Inventor: By his atti

Anited States Patent Pffice

TIMOTHEUS VOGELMANN, OF HAMILTON, OHIO.

Letters Patent No. 67,235, dated July 30, 1867.

IMPROVED STEP-LADDER.

The Schedule referred to in these Aetters Patent and making part of the same.

TO ALL WHOM IT MAY CONCERN:

Be it known that I, TIMOTHEUS VOGELMANN, of Hamilton, in Butler county, in the State of Ohio, have invented certain new and useful improvements in Step-Lauders; and I do hereby declare that the following is a full and exact description thereof, reference being had to the accompanying drawings, and to the letters of reference marked thereon.

Figure 1 represents my improved ladder complete.

Figure 2 represents the same, adjusted as an extension-ladder, part being broken away.

Figure 3 is a part of one of the rails, to show the double hook and bracket.

Figure 4 represents the sliding clasp and part of the hinge detached.

My improved ladder is designed to be used as a self-sustaining step-ladder, and as an adjustable extension-

ladder, which may be folded in a compact manner for transportation.

The drawings represent the ladder A, with steps 10, having the ladder B hinged to it, the latter being made with "rounds" instead of steps. The ladder A is made with grooves, a, in the edges of its rails, in which the tongues b of clasps C fit loosely, so as to be easily adjusted up and down, as occasion may require. The strap d of clasp C extends out, as seen at d', to form a hinge for the ladder B. The traversing blocks f are part and parcel of the same piece with tongues b, and this portion of the clasp may be made of wood, and the part d d' may be made of iron, and bolts or rivets may be used to connect them. The ribs g, on the edges of the rails of the hinged ladder B will fit into the grooves a a of ladder A, in which grooves the tongues b will slide to adjust the ladder B to any desired position. Ladder B, when standing as a support for ladder A, as represented in fig. 1, is so adjusted, by sliding the hinge-clasp C, as to bring the upper round o under the hooks h, which are turned upon their hinge upwards for the purpose of fastening the ladder B, by preventing clasps C from sliding. The metal double hooks h are formed with a shoulder, and are secured on the inner sides of the rails of ladder A by a screw and curved bracket, i, which permit the hooks h to be moved upon the hinge or screw pivot n in the arc of a circle up or down, to bring either of the hooks upon a round of ladder D to support it either as a step-ladder or as an extension-ladder, seen in fig. 2. In adjusting double hooks h, the shoulders formed upon their shanks at 5 will move along the inner curved edges of brackets i, which assist in strengthening the fastening. The brackets i serve to limit the movement of the hooks h in both directions. The cord m, fastened by one end to a round of ladder B, may be readily secured to or detached from the double spring-catch under the step 10', to hold ladder B from moving outwards, when the whole structure is adjusted as a stepladder. When the ladders are adjusted for the extension-ladder, either of the rounds o and p may be brought in connection with hooks h, which, together with the hinge-clasp C, constitute a secure fastening to retain the two ladders in a parallel relation to each other, and the ribs g of ladder B fit in the grooves a of ladder A, and thereby prevent lateral strain on the hinge-clasp and double hooks h. The hinge-clasp C, with its ladder B, may be moved in either direction past the double hooks h, by adjusting the hooks so that the upper round o will fit. into the depression at the vertex of the shank of the double hook; and as the clasp moves past the hooks the round o will cause the hooks to turn on their joints either up or down, according to the direction the ladder B is at the time of being moved.

From the foregoing description it will be understood that my ladder will serve the double purpose of a step-ladder and an extension-ladder, and may be conveniently folded together, or the two sections or ladders detached from each other by sliding the hinge-clasp off of the ends of the rails of ladder A.

Having fully described my improvements in step-ladders, what I claim therein as my invention, and desire to secure by Letters Patent, is—

- 1. The ladder A, constructed with the grooves a a, in combination with the ladder B, constructed with the ribs g, arranged and operating in the manner and for the purpose described.
- 2. The hinge-clasp C, represented in fig. 4, in combination with the rails of-ladder A, all constructed, arranged, and operating in the manner and for the purpose described.
- 3. The combination of double hooks h and brackets i, constructed, arranged, and operating with hinge-clasp C and ladder B, in the manner and for the purpose specified.

In testimony whereof I have hereunto set my hand this 27th day of February, 1867.

TIMOTHEUS VOGELMANN.
