United States Patent Office.

FREDERICK W. WIESEBROCK, OF NEW YORK, N. Y., ASSIGNOR TO JOHN GEORGE GILLIG AND ADAM E. SCHATZ; SAID SCHATZ ASSIGNOR OF THREE-EIGHTHS TO THEODORA WIESEBROCK, ALL OF SAME PLACE.

PROCESS OF AND APPARATUS FOR DESULPHURIZING AND PREPARING ORES.

SPECIFICATION forming part of Letters Patent No. 241,108, dated May 3, 1881.

Application filed October 7, 1879.

To all whom it may concern:

Be it known that I, FREDERICK W. WIESE-BROCK, of the city of New York, county of New York, State of New York, have invented 5 a new and useful Process of and Apparatus for Desulphurizing and Preparing Ores for the Extraction of Metals therefrom, of which the

following is a specification.

In order to thoroughly effect the desulphuri-10 zation of ores, it is necessary that the same should be subjected to the action of oxygen while in a highly-heated state, in order that the sulphur may be liberated. Heretofore this has been accomplished by passing a flame 15 commingled with atmospheric air into a body of the ore by blowing a current of pulverized ore into the flame of a furnace, or by forcing a jet or jets of atmospheric air into a highlyheated furnace, into which the ore, in a re-20 duced condition, is simultaneously introduced.

By the above-named methods it has been found almost impossible to thoroughly desulphurize ores containing a large percentage of sulphur, and such methods, moreover, are tedi-

25 ous and expensive.

The object of my invention is to obviate these objections and provide a means by which the ore may be thoroughly desulphurized, no matter what the percentage of sulphur may be, 30 and at a great reduction of time and expense; and to this end the invention consists, first, in a process for desulphurizing ores by dropping the finely-powdered ore into the oxidizing-flame of a compound blow-pipe injector, the said 35 flame carrying an excess of oxygen with the blast-flame, whereby the air and ore are highly heated, and regulating the supply of ore and the strength of the blast to carry the ore entirely through retorts or chambers into suitable 40 receivers, where the highly-heated ore is oxidized, and to convey the fumes resulting from the desulphurization into gatherers or condensers, where they are condensed and collected; second, in an apparatus for desulphurizing ores, 45 of the combination of a series of retorts, provided with tubes or hoppers having feed-conveyers, with a series of blow-pipe injectors for heating and conveying the ores through the retorts by means of blast-flames of carbureted 50 and atmospheric air, as more fully hereinafter

specified; third, in an apparatus for desulphurizing ores, of the combination of the feeding mechanism, the blow-pipes, and the retorts above mentioned, and a retort provided with a suitable conveyer and located in a suit- 55 able furnace, as more fully hereinafter specified; fourth, in the combination, in an apparatus for desulphurizing ores, of the feeding mechanism, blow-pipes, and retorts, one or more receivers connected with a flue leading 60 to a condenser or gatherer, as more fully hereinafter set forth; and, fifth, in the combination, with the retorts and hoppers, the blow-pipe injectors, and a series of receivers, of a furnace having a flue leading to the condenser, 65 as more fully hereinafter set forth.

In the drawings, Figure 1 represents a side elevation of the apparatus employed in carrying out the invention. Fig. 2 represents a front elevation. Fig. 3 represents a vertical 70 section of the same; and Fig. 4, a plan of the air-carbureting tank, the cover being removed.

The letter A indicates a hopper attached to a feed-pipe, a, into which it opens. The said feed-pipe is provided with a screw-conveyer, 75 a', by means of which a gradual or regulated delivery of ore to the retort B may be maintained. The said feed-pipe is preferably located at a greater elevation than the retort, in such manner that the ore may fall into the retort 80 from above. One end of said retort is open for the introduction of the blast-flame, and at the other end the retort is connected to a receiver, B', which is of sufficient size to permit the blast to expend its power therein, so as to 85 allow the ore to settle to the bottom of the same. The said receiver B' has a funnel-shaped bottom, which serves as a hopper, and is connected. with a feed-pipe, b, provided with a screw-conveyer, b', for the purpose of carrying the ore 90 to a retort, C, with which said pipe b is connected. Theretort C is substantially similar in construction to the retort B above mentioned.

The letter C' indicates a receiver similar to the receiver B', the said receiver being con- 95 nected with the retort C. The bottom of said receiver is connected with a retort, D, similar to the retorts B and C before mentioned, by means of a tube, c, provided with a screw-conveyer, c'. The last-mentioned retort commu-roo

nicates with an upright flue, D', which connects at its bottom with a retort, F, provided with a screw-conveyer, f, which is of less diameter than the said retort, in order to allow 5 an unobstructed passage of atmospheric air through the retort to assist in the final oxidization of the ore, as more fully hereinafter described.

The letter G indicates a furnace, in which 10 said retort F is located, the retort passing entirely through the furnace, which is provided with proper doors, g g', and draft-openings 1 2 3 4.

The letters QRS, Fig. 3, indicate flues lead-15 ing from the furnace to the chimney g^2 , through which the products of combustion escape.

The receivers B' C' D' communicate with the flues E E', which lead to the condensers E2, and are inclined in order to prevent the ac-20 cumulation of the ore therein.

The condenser is provided with a perforated or foraminous partition, E3, near its upper end, through which a stream of water is caused to flow into the condenser in a shower or spray, 25 in order to arrest the fine particles of ore and prevent their escape.

The respective screw-conveyers above mentioned are each provided at one end with bevelgear wheels z, gearing into bevel-gear wheels z'30 on a shaft, H, so as to convey the ore to the respective retorts in proper quantities.

The letter I indicates a blower having a blastpipe, I' and I2, which latter is provided with a stop-cock, i. The pipe I' passes through the 5 furnace in order that the air may be heated, and is provided at one end with the branch pipes i' i^2 i^3 , which are provided with suitable stop-cocks, and lead respectively to the nozzles P P' P2, the said pipes projecting into said o nozzles, as shown in Fig. 3, forming a blowpipe injector.

The letters J J' indicate oil-tanks, and K an intermediate air-carbureting tank, which communicates with the tank J by means of a pump, 5 J², pipe j, and pipe L. The supply-pipe L has a stop-cock, L2, and branches L', the said branches connecting with a series of pipes, ll, which pass through the side of the carbureting-tank into the same, being perforated at o their inner ends. The said tank K is provided with partitions k k, as shown in Fig. 4, the alternate partitions being set in such a manner that the space between them forms a circuitous channel, as shown by the arrows.

The letter M indicates an overflow-pipe inserted in the tank K at its bottom, extending sufficiently into the tank to maintain a proper quantity of oil therein. The lower end of said pipe leads into the tank J', in order to convey the overflow-oil from the tank K to said tank J'.

The blast-pipe I² connects with the carbureting-tank at one end of the circuitous channel, as shown at T, Fig. 4 of the drawings, and from the other end of said channel extend the pipes ; o o' o², provided with suitable stop-cocks, the

nozzles P P' P2, to convey the carbureted air to the same, and to regulate the flow for increasing or diminishing the blast-flame in its action upon the ore.

The letter N indicates a pipe connected at one end to the tank J, and provided with branches N' N2 N3, the said pipe and branches being provided with suitable stop-cocks. The ends of the said pipe N and the branches N' N2 75 pass through the nozzles P P' P2 and connect with the ends of the blast-pipe injectors.

The branch N³, Fig. 1, is connected with the furnace, and is intended to convey oil to the same from the tank J, to be used as fuel when 80 desired.

The branches N' N² and pipe N are for the purpose of feeding oil to the nozzles when desired.

The operation of my invention is as follows: 85 The reservoir J' is properly filled with oil. A suitable quantity is then pumped into the tank J. This oil, flowing through the pipe L, passes into the perforated pipes l l, and is distributed in spray between the partitions k k, and drops 95into the bottom of the carbureting-tank, where it collects until it reaches the end of the overflow-pipe M. Having heated the air-blast pipe and the retorts and receivers by means of the furnace, so as to prevent the absorption of heat 95 from the blast-flames, the apparatus is in condition to commence the process of desulphurization. The hopper A is then charged with the ore properly comminuted or pulverized, and the blower is put in operation. The stop- 100 cock L² is then opened, allowing the oil to flow into the carbureting-tank, the stop-cock i of the blast-pipe I² being also opened. A current of air is thus forced through the channels k kand through the spray of oil, evaporating and 105 absorbing the oil in its passage. The stopcocks of the blast-pipe injectors and gas-pipes are now opened and the gas or carbureted air ignited, after which the retorts are ready to receive the ore. The shafting is then set in 110 motion, rotating the screw-conveyers, so as to feed the ore to the apparatus. The delivery of theore is regulated by the velocity of the shafting, which is adjusted so as to deliver the ore at greater or less speed, according as the per- 115 centage of sulphur in the same varies—the larger the percentage of sulphur the slower the feed, and vice versa.

The flame produced by the carbureted air is sufficient to desulphurize ore containing a very 120 large percentage of sulphur; but should it be desired to still further augment its intensity, the stop-cock of the oil-pipe N may be opened, so as to allow a proper quantity of oil to flow directly into the current of heated air in the 125 blast-pipe, which almost instantly evaporates and ignites the oil and forms an increased flame, which is also carried into the retorts. The current of blast-flame, as it is forced into the retorts, carries with it an additional supply of 130 air, which enters around the blast-flame of the said pipes connecting respectively with the linjector, whereby a powerful desulphurizing

241,108

flame is projected into the retorts, directly into the ore as it falls into the same, insuring the most thorough heating prior to reaching the

receiving or oxidizing chambers.

These retorts are of a length sufficient to cause the ore to be suspended in the blast-flame until the same is sufficiently heated in order to absorb the oxygen from the atmosphere drawn in by the blast-flame, and as the blast-flame has sufficient oxygen for supporting its own combustion, the oxygen drawn in at the mouth of the retort by the force or impetus of the blast-flame is, by its passage through the retort, heated, so that on coming in contact with the heated ore the oxidation of the same is facilitated and insured.

It is obvious that the fine particles of ore, by reason of the force of the flame-blast, are kept in constant suspension and agitation, thus 20 exposing them thoroughly to the action of the flame, by means of which the sulphur is eliminated. The particles of ore, upon reaching the end of the retort, are carried into the receiver B', which is of such size and length as to allow 25 the force of the blast to nearly expend itself therein, but at the same time permit the highlyheated particles to be thoroughly agitated and oxidized without being carried over into the condensers to any great extent, so that they 30 will finally settle in the bottom of said receiver, while the fumes pass over to the condenser through the flues by the slight force still exerted by the blast-flame, thus obviating the injurious results attendant upon carrying the 35 fumes and gases along with the ore-particles, as when thus carried along with the ores the particles are liable to become enveloped with the sulphurous fumes liberated by the heat, and thus oxidation is retarded or wholly pre-40 vented.

The ore, after settling in the receiver B, passes through the successive retorts until it finally reaches the retort F, from which it is discharged into a suitable receptacle.

Thus it is evident that a greater number of retorts and receivers than herein shown and described may be employed, if desired, whereby much expense and labor may be saved in handling ores where it is necessary to subject the same to the desulphurizing process a number of successive times.

After the fumes and fine ore-particles pass through the flue E, they enter the condenser E², where, in their ascension, they are met by the water-spray, and are carried downward into a suitable tank or receiver and collected, and, if necessary, the fine particles of ore may be again passed through a retort, and thus almost all of the metal saved.

When it is necessary to chloridize the ores, 60 mechanical means for the introduction of the necessary ingredients and any suitable menstruum may be provided for the purpose.

Having thus described my invention, what I claim, and desire to secure by Letters Pat- 65

ent, is—

1. The process herein described of desulphurizing ore, which consists in dropping the finely-powdered ore into the oxidizing-flame of the compound blow-pipe injector, admitting excess 70 of air with the blast-flame, whereby the air and ore are highly heated, and regulating the supply of fine ore and the strength of the blast-flame to carry the ore entirely through retorts or chambers into receivers, where the highly-75 heated ore is oxidized, and the fumes resulting from oxidation into condensers or gatherers, substantially as described.

2. In an apparatus for desulphurizing ores, the combination of the series of retorts, provided 80 with tubes or hoppers having feed-conveyers, with the series of blow-pipe injectors for heating and conveying the ores through the retorts by means of blast-flames of carbureted and atmospheric air, all substantially as and for the 85

purpose specified.

3. In an apparatus for desulphurizing ores, the combination of the series of retorts provided with tubes or hoppers having feed-conveyers, the series of blow-pipe injectors for heating and 90 conveying the ores through the retorts by means of blast-flames of carbureted and atmospheric air, and the retort F, provided with conveyer f, located in the furnace G, all substantially as and for the purpose specified.

4. The combination, in an apparatus for desulphurizing ores, of the series of retorts provided with tubes or hoppers having feed-conveyers, the series of blow-pipe injectors for heating and conveying the ores through the retorts by means of blast-flames of carbureted and atmospheric air, the receivers B' C' D', flue E, and condenser E², all substantially as and for the purpose specified.

5. The combination, in an apparatus for desulphurizing ores, of the series of retorts and hoppers, each of the latter provided with a conveyer, the series of blow-pipe injectors, the receivers B' C' D', furnace G, flue E, and condenser E², all substantially as and for the purpose specified.

In witness I have hereunto set my name this 4th day of October, 1879.

FREDERICK W. WIESEBROCK.

In presence of— FREDERICK OPPERMANN, Jr., JOHN GEO. GILLIG.
