TRAVELING CRANE, DERRICK, &c.

No. 272,988.

Patented Feb. 27, 1883.

Attest: Halle Towler Min A. Gehoenborn

John Thompson by A. II. Evans & Co.

United States Patent Office.

JOHN THOMPSON, OF BUCYRUS, OHIO, ASSIGNOR TO THE BUCYRUS FOUNDRY AND MANUFACTURING COMPANY, OF SAME PLACE.

TRAVELING CRANE, DERRICK, &c.

SPECIFICATION forming part of Letters Patent No. 272,988, dated February 27, 1883.

Application filed January 17, 1883. (No model.)

To all whom it may concern:

Be it known that I, John Thompson, of the city of Bucyrus, county of Crawford, and State of Ohio, have invented certain Improvements in Traveling Cranes, Derricks, and Similar Devices; and I hereby declare the following to be a full, clear, and exact description thereof, reference being had to the accompanying drawings, making a part of the specification, in which—

Figure 1 is a horizontal sectional view of the lateral swinging mechanism of a traveling crane or similar device. Fig. 2 is a vertical section on the line x x of Fig. 1.

My invention relates to means for operating the chain-drums of traveling cranes, and has for its object to facilitate the handling of such machinery.

My invention consists of the details of con-20 struction of a friction-clutch mechanism and operating parts, as hereinafter fully described, and specifically set out in the claims.

In order that those skilled in the art may make and use my invention, I will proceed to describe the manner in which I have carried it out.

In the said drawings, I is the driving-shaft, to which the power is applied, and on it are keyed pinions K L, the pinion K meshing di-30 rectly with wheel A and pinion L meshing with intermediate pinions M N, which engage wheel B. By this gearing, when wheel A is revolved in one direction wheel B revolves in the opposite direction, and vice versa. The 35 wheels A B are loose upon shaft C, to which are keyed the chain drums a a, which swing the crane-boom in their rotation. Between wheels A B, around shaft C, is a collar, D, having four projecting arms, ttt't', which op-40 erate through turn-buckles h H, whose screws h' h' connect with arms t t' and sliding friction-shoes G G by means of pin or ball-joints, for a purpose hereinafter described. The shaft C is centrally bored from its end down to a 45 point between wheels A B, where a slot, s, (shown in Fig. 1,) is cut to the circumference. Within the central bore of shaft U is placed a l

rod, e, the inner end of which is secured to collar D by a key, k, so that a reciprocation of rod e will move collar D back and forth on 50 the shaft within the limits of the slot s. A yoke, P, at the end of shaft C supports a crank, W, which is connected to the outer end of rod e by a link, V, and the other arm of the crank, by means of connecting-rod Y, is connected 55 to a lever, Z, having a toothed rack properly and conveniently located on the platform, whereby the operator can reciprocate rod e back and forth and change the position of collar D in relation to wheels A B. As collar D 60 is forced toward wheel B the arms t t' move the turn-buckles h H toward the face of the wheel D, and, moving as they do on their pin or ball-joints, they force outward the frictionshoes G G, whose curved faces, coming in 65 contact with the interior surface of the rim of wheel D, clutch it to shatt C, so that the power through pinions L M N rotates the shaft and chain-drums in one direction. By reversing the movement of rod e the clutches seize 70 wheel A in a similar manner, and pinion K and wheel A rotate shaft C in the opposite direction.

The faces of the clutch-shoes G G may be covered with vulcanized fiber or any other de- 75 sirable material.

Having thus described my invention, what I claim as new, and desire to secure by Letters Patent, is—

1. In a traveling crane or derrick, the pow- 80 er-shaft I, pinions K L M N, shaft C, and loose wheels A B, in combination with collar D, provided with arms t t', turn-buckles h H, and sliding friction-shoes G G, all constructed, arranged, and operated as set forth.

2. The loose wheels A B, central hub or collar, D, provided with a friction clutching device in combination with the hollow slotted shaft C, rod e, and operating crank and lever, substantially as specified.

JOHN THOMPSON.
