## G. WESTINGHOUSE, Jr.

APPARATUS FOR RELIEVING PRESSURE IN BRAKE CYLINDERS.

## IJNITED STATES PATENT OFFICE.

GEORGE WESTINGHOUSE, JR., OF PITTSBURG, PENNSYLVANIA.

## APPARATUS FOR RELIEVING PRESSURE IN BRAKE-CYLINDERS.

SPECIFICATION forming part of Letters Patent No. 300,543, dated June 17, 1884.

Application filed November 30, 1883. (No model.)

To all whom it may concern:

Beitknown that I, GEORGE WESTINGHOUSE, Jr., a citizen of the United States, residing at Pittsburg, county of Allegheny, State of Penn-5 sylvania, have invented or discovered a new and useful Improvement in Apparatus for Relieving Pressure in Brake-Cylinders; and I do hereby declare the following to be a full, clear, concise, and exact description thereof, refer-10 ence being had to the accompanying drawings, making a part of this specification, in which—like letters indicating like parts—

Figure 1 is a sectional view (enlarged) of the valve for relieving the air-pressure in the 15 brake-cylinder. Fig. 2 is a view of the bottom of a car, showing the usual arrangement of air-reservoir, brake-cylinder and pipes, the signaling-pipe, and the exhaust-valve. Fig. 3 is a side view of an engine-cab, showing the 20 arrangement of the main reservoir, the auxiliary signaling-reservoir, and the necessary pipe-connections.

My invention is designed for use in connection with what are commonly known as "au-25 tomatic brakes," and I have shown it as applied to the Westinghouse automatic brake, in connection with a signal-operating mechanism in which a fluid pressure in excess of atmospheric pressure, but less than the press-30 ure in the brake apparatus, is ordinarily maintained.

It sometimes happens that the brakes are applied accidentally by the bursting of the hose-connection, and the object of this inven-35 tion is to provide a means additional to that ordinarily used for releasing the brakes, and to this end I utilize the signal-operating pipe to convey pressure from the main reservoir to a valve mechanism the ports of which con-40 nect with the brake-cylinder.

A is the main reservoir, attached, as usual, under the foot-board of a locomotive. B is the signaling-reservoir. A' is the auxiliary reservoir, usually arranged one under each 45 car, and C is the brake-cylinder, which is provided with a piston and piston-stem connected with a brake-lever in any suitable way.

The location of the triple valve is shown at a and the brake-pipe at a', Fig. 2. The triple 50 valve and brake-cylinder are connected by the

with a reducing-valve, R. This valve R is connected by a pipe, b, through a short branch to a signaling-valve, R', on the end of the signaling-reservoir B, and the signaling-valve R', 55 is connected by a pipe, s, to the signal s, which in this case is a whistle. By the use of the reducing-valve Ronly sufficient pressure is maintained in the signaling-reservoir and its pipes extending under the train to operate the sig- 60 nal. The pipe b is extended above the signaling-valve, and is connected with one of the ports of a cock, f, the other port of this cock being connected by a pipe, f', with the main reservoir A. Near the main reservoir, but 65 above the reducing-valve, the pipe b is provided with a branch b', which is connected with the signaling-pipe  $b^2$ , extending under the cars, the signaling-pipe under each car being connected with the pipe under the tender 70 or other cars by the usual hose and coupling.

Under each car the signaling-pipe is provided with a branch,  $b^3$ , which is connected by an elbow,  $b^4$ , to the valve mechanism D, which is connected to the same head of the 75 brake-cylinder as the pipe  $a^3$ , leading from the triple valve a. This valve mechanism D, Fig. 1, is formed of two parts, d and d', recessed at their ends, which recesses form, when the parts are secured together, the diaphragm- So chamber  $d^3$ . The part d is also provided with a longitudinal passage,  $d^2$ . In the chamber  $d^3$ is placed the flexible diaphragm  $d^3$ , which is held at its edge between the two parts d and d'of the valve-case. Within the part d'is formed 85 a valve-chamber,  $d^{\circ}$ . From one end of this chamber  $d^6$  extends a passage,  $d^7$ , connecting the chamber  $d^6$  with the recess  $d^3$ . This passage  $d^7$ is intersected by an exhaust-port,  $d^3$ . The other end of the chamber  $d^{6}$  is tapped, and into the 90 end of this chamber is screwed the plug  $d^n$ . This plug also is screwed into the cylinderhead, and is provided with a central longitudinal passage,  $d^{10}$ , and a series of two or more inclined passages,  $d^{H}$ . These inclined 95 passages connect the chamber d<sup>6</sup> with the passage  $d^{10}$ , midway of its length. The end of the passage  $d^{\dagger}$  which opens into the valvechamber  $d^{\epsilon}$  is provided with a valve-seat, against which is normally pressed the valve c 100 by the spring c', which surrounds one of the pipe  $a^3$ . The main reservoir A is provided | valve-stems  $c^2$  and bears at its ends against

the valve c and the plug d. The valve-stem  $c^2$  extends throught he valve-chamber  $d^6$ , and enters and is guided by the central passage,  $d^{10}$ , of the plug  $d^9$ . The other side of the valve is provided with a short-winged stem,  $c^3$ , which extends into the passage  $d^7$  and guides the valve c to its seat. Against the end of the winged stem bears the pressure-stem e, which works in the enlarged part of the passage  $d^7$  to the right of the exhaust-port  $d^8$ . The end of this pressure-stem, where it extends into the exhaust-port  $d^8$ , is provided with wings, and its end which extends into the diaphragm-chamber  $d^3$  bears by its enlarged head e' against the diaphragm  $d^5$ .

The operation of my mechanism is as follows: The main reservoir A, the signal-reservoir B, the auxiliary reservoirs A' under the cars, and the brake and signal pipes are all charged with fluid under pressure, the press-20 ure in the signal reservoir and pipes being less than that in the other reservoirs and pipes. The brakes having been applied by the bursting or breaking of the brake-pipes, to release them the engineer turns the cock f, thereby 25 allowing the full pressure of the main reservoir to act in the signal-pipes. This pressure, acting on the diaphragm  $d^5$ , moves the stem  $e^3$ , and through that the valve c is unseated, thereby allowing a free exhaust from the brake-30 cylinder through passages  $d^{10}$  and  $d^{11}$ , the chamber  $d^6$ , the passage  $d^7$ , and the exhaust-port  $d^{8}$ , and thus relieving the wheels from the pressure of the brake-shoes.

The spring c' should have sufficient tension to withstand the normal pressure in the signal-pipes, which, as before stated, is less than that in the main and auxiliary reservoirs and the brake-pipes.

Under each car is formed a branch, m, in the signaling-pipe, said branch extending up into the car, where it is provided with a suitable cock to enable the conductor to signal to the engineer by allowing a slight escape of fluid from the signal-pipe.

In so far as relates to the construction of the parts hereinbefore described, I consider all known substitutes and equivalents therefor as within the scope of my invention.

I claim herein as my invention—

50 1. The method of releasing brakes operated by an artificially-created fluid-pressure, con-

sisting in releasing the pressure in the brakecylinder by increasing the fluid-pressure on a movable diaphragm, substantially as set forth.

2. The combination of a brake-cylinder, an 55 exhaust-valve, an independent signal-pipe, the main reservoir, and a cock for admitting the full pressure of the main reservoir into the signal-pipe, substantially as set forth.

3. In a fluid-pressure brake mechanism hav- 60 ing a brake-pipe for operating the brakes by the use of any desired pressure, and a signal-pipe normally charged with a less pressure, both connected with the brake-cylinder, and, in combination therewith, a pressure-relieving mech- 65 anism arranged in the line of communication from the signal-pipe to the brake-cylinder, and a cock arranged in the pipe which connects the main reservoir with the signaling-pipe, substantially as set forth.

4. A fluid-pressure brake and signaling apparatus having, in combination, a brake-pipe and an independent signaling-pipe, a connection from one to the other through a common reservoir, and means for keeping the signal-75 ing-pipe continuously charged with fluid-pressure, but at a less pressure than that normally contained in the brake-pipe, substantially as set forth.

5. In combination with a brake-cylinder, C, 80 and a pipe,  $a^3$ , for the supply and discharge of fluid-pressure in the normal operation of the brakes, an independent exhaust-valve, a movable diaphragm for operating said valve, a spring to hold said valve to its seat as against 85 normal pressure, and a fluid-pressure-supply pipe and cock for applying an excess of fluid-pressure to unseat said valve, substantially as set forth.

6. In an exhaust-valve, the combination of 90 the parts d and d', the part d having the passage  $d^2$  and recess  $d^3$ , the part d' having the passages  $d^{10}$ ,  $d^{11}$ ,  $d^6$ ,  $d^7$ , and  $d^8$  and recess  $d^3$ , the diaphragm  $d^5$ , the presser-stem e, the valve e, provided with guides, and the spring e', 95 substantially as set forth.

In testimony whereof I have hereunto set my hand.

GEORGE WESTINGHOUSE, Jr. Witnesses:

R. H. WHITTLESEY, DARWIN S. WOLCOTT.
