LOZENGE MACHINE.

No. 376,068.

Patented Jan. 10, 1888.

United States Patent Office.

OLIVER R. CHASE, OF BOSTON, MASSACHUSETTS.

LOZENGE-MACHINE.

SPECIFICATION forming part of Letters Patent No. 376,068, dated January 10, 1888.

Application filed November 24, 1886. Serial No. 219,750 (No model.)

To all whom it may concern:

Be it known that I, OLIVER R. CHASE, of Boston, in the county of Suffolk and State of Massachusetts, have invented certain new and useful Improvements in Machines for Manufacturing Lozenges, of which the following, taken in connection with the accompanying

drawings, is a specification.

My invention relates to machines for manufacturing confectionery, and especially confectionery lozenges, and is an improvement upon the machines described in Letters Patent Nos. 279,132 and 279,913, granted to me June 12, 1883, and June 26, 1883, respectively; and it consists in certain novel features of construction, arrangement, and combination of parts, which will be readily understood by reference to the description of the drawings and to the claims to be hereinafter given.

The machine described in Letters Patent No. 279,132 was designed originally for feeding the sugar-paste into sticks or rods; but by an improvement in the discharging nozzle now embodied in this application it has been 25 used for molding the paste into a sheet or ribbon of, say, six or eight inches in width and about one-half an inch in thickness, more or less. The sheet or ribbon so formed was then taken by hand from said machine and trans-30 ferred to the feeding apron of the machine described in Letters Patent No. 279,913, where it was further reduced in thickness, planished, and then cut into lozenges. This mode of operation involved the running of two independ-35 ent machines and an extra handling of the material, which my present invention obviates.

In the drawings, Figure 1 is a side elevation of a machine embodying my invention. Fig. 2 is a longitudinal vertical section of the same.

40 Fig. 3 is a transverse vertical section on line 11 on Figs. 1 and 2, looking toward the delivery end of said machine, said figure being drawn to an enlarged scale. Fig. 4 is a vertical longitudinal section of a portion of the delivery end of the machine, also drawn to an enlarged scale. Fig. 5 is a side elevation of the upper portion of Fig. 4, looking in the opposite direction to that in which Fig. 4 is viewed, and drawn to the same scale as Figs. 3 and 4. Figs. 6 and 7 are details illustrating the manner of vibrating the printing-form

and holding it in position while giving an im-

pression or taking ink. Figs. 8 and 9 are respectively a plan and an elevation of the oscillating type-carrying bar. Figs. 10 and 11 are 55 respectively an elevation and a transverse section of the stripper-bar. Figs. 12, 13, and 14 are respectively an end elevation, a transverse section, and a front elevation of the rectangular discharge nozzle for forming the sheet 60 of sugar paste; and Fig. 15 is an inverted plan of a portion of the cutters, the embossing and printing bars, and the bail-like stand for carrying said bars. Fig. 16 is a partial longitudinal section illustrating a modification, to be 65 hereinafter referred to.

In the drawings, A A are the side frames of the machine, connected together by the tiegirts A' A' and the plates A² and P, as shown in Fig. 2.

70

Upon the plate A² is mounted the vertical cylinder B, provided with the revolving screwpiston B' and one or more horizontal screwfeeders, B2, all constructed, arranged, and operating substantially as described in the said 75 Letters Patent No. 279,132, and with the inclined feed table B3, from which the material is fed to the cylinder B, from which it is discharged in the form of a sheet or ribbon, a, through the rectangular opening b in the noz-80 zle C, as shown in Fig. 2. The nozzle C has pivoted therein the plate b', the free or outer edge of which may be adjusted by the setscrews b^2 , for the purpose of varying the thickness of the sheet of material that can be deliv- 85 ered therefrom, as shown in Figs. 2, 13, and 14. The sheet of material a, when delivered from said nozzle, falls upon the inner end of the apron b^2 , mounted upon the rolls b^3 and b^4 , and is carried by said apron beneath the end- 90 less band or apron c, mounted upon the rolls c' and c^2 , and upon the moving apron or endless band c^3 , mounted upon the rolls c^4 and c^5 , as shown in Fig. 2. The sheet of material, as it passes from the apron c^3 , where said apron 95passes around the roll c^5 , is turned downward

upon the rolls e', e^2 , and e^3 , as shown. The rolls d and d' are partially surrounded by the endless bands or aprons d^4 and d^5 , respectively, which extend to and partially sur-

between the pressure-rolls d and d', where it

is reduced in thickness and compacted, and

then between the planishing-rolls d^2 and d^3 , and

deposited upon the moving apron e, mounted 100

round the rolls d^6 and d^7 , respectively, as shown. The aprons b^2 , c, d^4 , and d^5 each have placed thereon a quantity of flour or powdered starch within a shallow hopper or receptacle, f, of 5 which said apron forms a moving bottom, as described in said Letters Patent No. 279,913, whereby the sheet or ribbon of paste has deposited upon each side thereof a thin coating of said flour or starch to prevent it from ad-10 hering to any of the aprons or the planishingrolls. The aprons b^2 , c, d^4 , and d^5 may be made taut by adjusting the rolls b^4 , c^2 , d^6 , and d^7 in any well-known manner.

The screw pistons or feeders B' and B² are 15 driven from the shaft D in the same manner as described in the before-mentioned Letters Patent No. 279,132, said shaft D being driven by a belt (not shown) leading from the drivingpulley D' to any suitable counter shaft. (Not

20 shown.)

The shaft D has mounted thereon the pulley D2, from which the belt D3 leads to the pulley D4, mounted upon the shaft D5, which has its bearings in the frames A A, and has 25 secured thereon the pinion g, which engages with and imparts motion to the gear-wheel D^6 on the shaft g', also mounted in bearings in the frames A A, and having mounted thereon the pinion g^2 , which engages with and imparts 30 motion to the gear-wheel E, mounted upon one end of the shaft of the roll b^3 , the opposite end of which shaft has secured thereon the gear-wheel h, which engages with and imparts motion to the gear-wheel h', mounted upon 35 the shaft of the roll c', as shown. The shaft of the roll b^3 has mounted thereon a pulley, from which the belt h^2 leads to a similar pulley on the roll c^5 , for the purpose of revolving said roll c^5 in unison with the roll b^3 and im-40 parting motion to the apron c^3 , for conveying the sheet of paste a to a position to be delivered to the pressure rolls d and d', as shown. The upper portions of the endless belts c^3 and e are supported between their carrying-rolls 45 by the bed-plates or tables c^6 and e^4 , respect-

Motion is imparted to the rolls d, d', d^2 , and d^3 and the aprons d^4 and d^5 from the roll c^5 by means of the gear-wheels i^5 , i^6 , i^7 , i^8 , i^9 , i^{10} , i^{11} ,

ively, as shown in Figs. 2 and 3.

50 and i^{12} .

The endless apron e has an intermittent motion imparted thereto by means of the crankpin i, set in the disk i', mounted upon one end of the shaft F, the connecting rod F', the le-55 ver i^2 , the pawl i^3 , and the ratchet-wheel i^4 , mounted on the shaft of the roll e' in substantially the same manner as described in said Letters Patent No. 279,913.

The shaft F has mounted thereon the gear-60 wheel F2, with which the pinion F3, mounted upon the shaft G, engages, to impart to said shaft F a rotary motion, said shaft G being revolved by means of the pulley G', mounted thereon, and a belt leading therefrom to a suit-65 able counter-shaft, which may be the same from which the shaft D is driven or an inde-

pendent one, as may be preferred, care being

taken to so proportion the several pulleys that said shafts G and D shall be driven at the

proper relative speed.

The shaft F has mounted thereon two eccentrics, H and H', which work in slots in the lower ends of the vertical bars H2 and H3, respectively, in such a manner as to impart to said bars a vertical reciprocating motion, said 75 bars being fitted to slide in dovetailed bearings in the inner faces of the stands I and I', bolted to the upper edges of the frames A A. as shown. To these bars H² and H³ is bolted the horizontal bar H4, having set therein a se- 80 ries of tubular cutters, k k, which project downward therefrom and surround the fixed pistons l, suspended from the under side of the fixed bar J, said cutters, when moved downward to cut lozenges from the sheet of 8; material a, passing through holes in the fixed bar J, supported upon the raised ribs of the bed-plate e^4 , as shown in Fig. 3. The shaft F also has mounted thereon the eccentric m, which works in the strap end of the eccen- 90 tric-rod m', which in turn is connected to the lever m^2 , firmly secured upon the rocker-shaft m^3 , mounted in bearings in the frames A and carrying the two arms $m^4 m^4$, the free ends of which are connected to the rods n n, having 95 bearings in the stands I and I' and carrying at their opposite ends the reciprocating lozengecarrying plate n', all constructed and operating substantially as described in said Letters Patent No. 279,943, except that the plate n', 100 instead of having a jointed flap, as described in said patent, has a fixed raised rib, n^2 , upon its inner edge, and except, also, that instead of the lozenge being brushed from the inner edge of said plate as said plate is moving out. 105 ward, as described in said patent, the lozenge is removed from the outer edge of said plate as it is moving inward after having been moved outward, as will be further described. The plate n' also has at each end thereof the raised 110 cam shaped rib n^3 n^3 , arranged to act upon the pendent arms of the elbow-levers n^4 , pivoted upon the arms or rods n^5 , to move said levers about their pivots and raise or lower the stripper-bar J', fitted to move vertically in slots n^6 , 115 formed in the outer ends of the arms n^5 , as shown in Figs. 1 and 4.

The stripper J' is composed of the central plate, o, arranged to fit the slots n^6 and to rest upon the free ends of the horizontal arms of 120 the elbow-levers n^4 at o', the two plates o^2 and o³, and the sheet or plate of vulcanized rubber o4, all secured together by screws or rivets, as

shown in Figs. 10 and 11.

When the plate n' is moved outward, after 125 having received from the cutters a series of lozenges, the outer throws of the cams n^3 coming in contact with the pendent arms of the levers n^4 causes the stripper-bar to be raised and held in such raised position until the 130 lozenges on said plate have passed outward beyond the rubber flap of the stripper-bar, when the inner throws of the cams n^3 will have passed from beneath the levers n^4 , when the

stripper-bar will descend to a position with | formed in said bar for the purpose, as shown the lower edge of the rubber flap o⁴ on a level with the upper surface of the plate n' behind the lozenges, and as the plate n' is again moved 5 inward the lozenges are brushed from said plate by said flap o^4 , or, more literally, the lozenges are prevented from moving back by said flap after they come in contact therewith and the plate is moved from beneath them, and ic they fall upon the apron p, mounted upon the roll p' and another roll (not shown) that may be at a considerable distance from the roll p'and mounted upon an independent stand, from which apron the lozenges are delivered to a 15 board or receptacle provided for the purpose.

Motion is imparted to the roll p' by the gearwheels K and L, mounted, respectively, on the shaft F and the shaft of the roll p', as shown in

Figs. 1, 2, 3, and 4.

23 A standard, M, is firmly secured to the upper end of each of the stands I and I' in such a manner that it may be readily removed by simply slackening the nuts p^2 p^2 and raising said standard to lift the holding-bolt out of 25 the open slot p^3 in the stand I and I'. In bearings formed in the upper ends of the standards M is mounted the roll q, and in bearings formed in the lower ends of said standards are mounted the two smaller rolls, q' q', and the impression 30 bar or platen q^2 , around which is strained the endless band q^3 of cloth, to serve as a color pad, upon which coloring-matter for printing mottoes in color upon the lozenges is distributed from the color-roll r by the cylindrical brush 35 r', assisted by the distributing-roll r^2 , as shown in Fig. 4. Rotary motion is imparted to the brush r' by means of the belt r^3 , leading from the pulley N on the shaft G to the pulley N' on the shaft of said brush, as shown in Fig. 4, 40 and the roll r is revolved by means of the pinion r^4 and gear-wheel r^5 , mounted, respectively, on the shaft of said brush r' and the shaft of said roll r, as shown in Fig. 1.

A bail-like stand, O, is securely bolted to 45 each of the vertically-reciprocating bars H2 and H³, so as to move up and down therewith, and upon its lower bar is adjustably secured the bar r^6 , from which is suspended so as to be adjustable vertically, by means of the threaded 50 bolts r^7 and the nuts r^8 and r^9 , the bar s, having formed in or secured to its under side a series of dies adapted to emboss upon the sheet of sugar-paste a row of ornamental figures or designs corresponding in number and distance 55 apart from center to center with the number and distance apart of the cutters k k, said bar r being secured to the stand O at a distance from the center of the line of cutters k k corresponding to a multiple of the distance which 60 said sheet of paste is fed forward at each intermittent movement thereof, all substantially as described in the before-mentioned Letters Patent No. 279,913.

O' is a rocker-shaft mounted in bearings s', 65 adjustably secured to the lower bar of the stand O by means of bolts arranged to be interchangeably inserted in either of the holes s^2 ,

in Fig. 15.

The shaft O' projects beyond its bearings at 70 each end, and has formed upon one of said projecting portions a tooth, s³, which engages with the rock-like teeth s4, formed on the edge of the stand I, as said shaft is moved up and down with the stands O, thereby imparting to 75 said shaft a semi-rotation about its axis. (See Fig. 6.) The opposite projecting end of said shaft is made square, and acts in conjunction with the edge of the stand I' to maintain said shaft in a fixed position as to rotation after it 80 has been moved about its axis a half-revolution both in its upward and downward movement, the edge of said stand I' having a recess, s⁵, formed therein at the proper point and of the proper length to permit the rotation of 85 said shaft when the tooth s^3 engages with the teeth s^4 , all as shown in Fig. 7.

The shaft O' has suspended therefrom, by means of the threaded bolts $s^6 s^6$ and nuts $s^7 s^7$, the bar s⁸, which may be adjusted toward or 90 from said shaft by said bolts and nuts and the set screw s⁹, as shown in Figs. 8 and 9. The bar s⁸ has secured thereto the plate t, of typemetal, having cast thereon a series of mottoes, the type composing which project from the 95 surface of said plate, and in the operation of the machine are alternately brought into contact with the endless-belt pad q^3 to take color therefrom and into contact with the upper surface of the sheet of sugar-paste a to print said 100 mottoes thereon, these operations being accomplished by the upward and downward movement of the stands O and the bars H² and H³, caused by the rotation of the eccentrics H and H'.

In order to present a fresh portion of the color-band to the type at each upward movement thereof, the band q^3 has imparted thereto an intermittent movement around the rolls qand q' q', as follows: The shaft of the roll q has 110 loosely mounted thereon one end of a togglelink, t', the opposite end of which is pivoted to one end of the toggle-link t^2 , which in turn is pivoted to the stand O at t^3 , as shown in Figs. 4 and 5.

To the link t' is pivoted the pawl t^4 , the toe of which is held in contact with the periphery of the ratchet-wheel t^5 , secured upon the shaft of said roll q by the preponderance of weight in the long or outer arm of said pawl, the 120 whole being so arranged that every downward movement of the stand O causes a partial straightening of the toggle, and as a consequence thereof a partial rotation of the roll qand a movement of the color-band around the 125 same. When the stand O is again moved upward, the pawl t is carried backward over the teeth of the ratchet-wheel t5, preparatory to its engaging with another tooth of said wheel, when the stand O is again moved downward. 13C

P is the inclined plate down which the waste from which the lozenges have been cut slides and falls into any suitable receptacle provided for the purpose.

The rubber flap of of the stripper-bar J' has its lower edge divided into a series of sections by vertical slits, as shown in Fig. 10, so as to present less resistance in case a lozenge should 5 stick to the plate n'when said plate is moving backward beneath the stripper bar.

The operation of my invention, I think, will be readily understood from the foregoing with-

out further explanation.

the little in the cases I propose to dispense with the aprons c^3 , d^4 , and d^5 and the rolls c^5 , d, d', d^6 , and d^r , and place the rolls d^s and d^s directly the rolls b^{\sharp} and c^{\sharp} , respectively, said: oxdots oxderror and the figure of the distance apart, as shown in Fig. 16, whereby the machine may be considerably reduced in In this is the factor to the factor length .
