T. W. HARVEY.

PORTABLE PHOTOGRAPHIC DEVELOPING BOX.

No. 385,264.

Patented June 26, 1888.

United States Patent Office.

THOMAS WILLIAM HARVEY, OF ORANGE, NEW JERSEY.

PORTABLE PHOTOGRAPHIC DEVELOPING-BOX.

SPECIFICATION forming part of Letters Patent No. 385,264, dated June 26, 1888.

Application filed February 27, 1888. Serial No. 265,413. (No model.)

To all whom it may concern:

Orange, in the county of Essex and State of New 5 Jersey, have invented certain new and useful Improvements in Portable Photographic Developing-Boxes, of which the following is such a full, clear, and exact description as will enable any one skilled in the art to which it apro pertains to make and use the same, reference being had to the accompanying drawings, forming part of this specification.

This invention relates to a portable watertight photographic developing - box, made 15 partly of a tinted glass impervious to actinic light, and provided with a tight-fitting removable cover, and with pipe-connections for introducing into and withdrawing from the box liquids used in developing a sensitized plate 20 which has previously been exposed in a camera, and after removal therefrom placed in the developing-box.

The great advantage of the invention is that it permits the operator to conduct the devel-25 oping process in white light or even in sunlight, under the most favorable conditions for observation. Incidentally it dispenses with the developing closets or chambers of considerable dimensions commonly employed, and 30 hence materially diminishes the cost of the appliances required for conducting the developing process.

The accompanying drawings of a photographic developing-box containing the inven-35 tion are as follows:

Figure 1 is a top view, partly in section. Fig. 2 is a transverse section taken through the plane indicated by the line x x on Fig. 1. Fig. 3 is a longitudinal section taken through to the plane indicated by the line y y on Fig. 1.

The drawings represent a shallow box slightly exceeding in its length and width the length and width of the plates for which it is intended to be used. It consists of a substan-45 tial rectangular frame, A, in a portion of which there is formed a receiving chamber, a, connected with the liquid supply pipe B. The inner wall of the receiving-chamber a is provided with a series of perforations, a'. The 5c liquids used in the developing process are sup-

the pipe B, and discharged therefrom through Be it known that I, Thomas William Har- | the perforations a' simultaneously upon differ-VEY, a citizen of the United States, residing at | ent portions of the photographic plate C, which is held in position by having its sides entered, 55 respectively, into the grooves D D, formed in the opposite sides of the frame.

The top E and bottom e of the box are each formed of a pane of suitably-tinted glass, and each pane is secured in a seat formed around 60 the rectangular frame and makes a water-tight joint therewith. The panes of glass at the top and bottom of the box are intended to be transparent, but must be so tinted as to exclude actinic light-rays from the interior of the box. 65 For this purpose ruby or yellow-colored glass may be employed, or, what is better still, a pane of glass ruby-tinted on one side and yellow-tinted on the other.

One end of the rectangular frame is pro- 70 vided with a slot, F, the extremities of which coincide in alignment with the grooves DD, formed, respectively, in the inner sides of the side members of the rectangular frame. The slotted end F' of the frame is elongated, in 75 order to provide the two laterally-projecting lugs ff, through which holes are respectively tapped, to receive the clamping-screws gg, by means of which the cover G is clamped to the frame. The bearing-face of the cover is pro-80 vided with the packing-strip G', of rubber or other elastic material, so that the cover G, when clamped in place, will make a watertight joint with the frame and securely close the slot F after the photographic plate C has 85 been introduced into the box.

The supply-pipe B is preferably provided with a stop-cock, B', and for abundant caution, in order to prevent the entrance of white light through the pipe into the box, is sinuously 90 curved, as shown. A flexible coupling-pipe, b, is connected at one end to the outer extremity of the supply-pipe B, and is intended to have its other end applied to the nozzle of an ordinary bulb-syringe, H. An air passage or pipe, 95 I, also sinuously curved and provided with a stop-cock, I', is inserted through one of the side members of the rectangular frame, so that when the cock I' is opened the pipe I will serve as an outlet for the air expelled from the inte-100 rior of the box when liquids are injected into plied through the receiving-chamber a, through | it, and will serve to let air into the box when

liquid is withdrawn therefrom through the

pipe B.

It will of course be understood that the developing-box may be varied in its shape and 5 in the manner of its mechanical construction without departing from the invention, the essential requirements of which are that the box shall have an opening allowing such access to its interior as will permit the introduction to therein of the plate which is to be developed; a movable cover, by means of which said opening can be closed water-tight; a transparent portion, which permits a photographic plate within the box to be visually observed during 15 the progress of the developing operation, but which will not admit into the interior of the box light which is actinic; and, finally, means for introducing into and withdrawing from the interior of the closed box the liquids used in 20 the developing process.

In practice the removal of a plate from the camera in which it has been exposed to the developing-box will be effected with the aid of a changing-box or a changing-bag, both of which 25 appliances, being well known, do not herein

need description.

After the plate has been introduced into the developing-box and the cover thereof fastened in place, the operation of developing and fix-30 ing the picture is performed by the use of the usual liquids without any further precaution against the exposure of the photographic

plate to white light.

When the top and bottom panes of glass are 35 each ruby-tinted on one side and yellowtinted on the other, the developing-box may be exposed even to sunlight without injury to the sensitized plate inclosed therein, excepting when such plate is very highly sensi-40 tized, in which case it will be better not to expose the developing-box to the direct rays of the sun nor to very brilliant white light.

By filling the bulb of the syringe with liquid and connecting its nozzle with the flexi-45 ble tube B and compressing the bulb such liquid is readily injected into the interior of the box and discharged in jets over the surface of the sensitized plate therein, the air cock I' being open during this operation. By then 50 closing the air-cock I' and removing the pressure from the bulb of the syringe the liquid in the box is readily withdrawn therefrom.

The developing-box, during the injection of the liquids employed, is held in a horizon-

55 tal or slightly-inclined position.

The tinted glass may be used for the top only of the box, in which case the developing of the picture can be observed by light reflected from the surface of the photographic

plate. It is, however, manifestly preferable (o to make both the top and the bottom of the box transparent, so that the box can be held up toward the light and the progress of the developing operation rendered plainly visible by light which shines through the photo- 65 graphic plate.

What is claimed as the invention is—

1. A portable photographic developing-box made partly of tinted glass impervious to actinic light, and provided with a tight-fitting re- 70 movable cover and with pipe-connections for introducing into and withdrawing from the box the liquids used in developing a picture upon a sensitized plate which has previously been exposed in a camera and after removal 75 therefrom placed in the developing box.

2. A photographic developing-box partly made of transparent tinted glass and adapted to contain a photographic plate, and provided with an internal receiving chamber having 80 perforations in its inner wall, for the purpose of effecting the simultaneous discharge upon different portions of the plate under treatment of liquid introduced into the said receivingchamber by means of a suitable pipe connected 85

therewith.

3. A photographic developing box made partly of tinted glass, in combination with a pipe for introducing into and withdrawing from the interior of said box the liquid em- 90 ployed in the developing process, and an air passage or pipe for letting air escape from the box when liquid is injected into it, and for permitting air to enter the box when the liquid : previously therein contained is withdrawn 95 from it.

4. A photographic developing box made partly of tinted glass and provided with an opening for permitting the introduction into the box of a photographic plate, in-combina- 100 tion with a removable cover faced with an elastic material, and a fastening for said cover for securing it to the box and closing the said opening water-tight after said photographic plate has been introduced into the box.

5. The herein-described photographic developing-box, made partly of tinted glass, substantially as and for the purpose set forth, in combination with the liquid supply pipe B, provided with the stop-cock B', and the 110 air-pipe I, provided with the stop-cock I'.

107

In testimony whereof I have hereunto set my hand, this 23d day of February, 1888, in the presence of two subscribing witnesses.

THOMAS WILLIAM HARVEY.
