T. E. RICHARD. PORTABLE EVAPORATING APPARATUS.

No. 481,675.

Patented Aug. 30, 1892.

T.E. Richard. By his Attorneys,

Harry D. amer. Deptachaupter

United States Patent Office.

THEOGENE E. RICHARD, OF LAKE CHARLES, LOUISIANA.

PORTABLE EVAPORATING APPARATUS.

SPECIFICATION forming part of Letters Patent No. 481,675, dated August 30, 1892.

Application filed April 5, 1892. Serial No. 427,876. (No model.)

To all whom it may concern:

Be it known that I, THEOGENE E. RICHARD, a citizen of the United States, residing at Lake Charles, in the parish of Calcasieu and State of Louisiana, have invented a new and useful Portable Evaporator, of which the following is a specification.

This invention relates to evaporators; and it has for its object to provide an improved portable evaporator particularly adapted for the evaporation of successions.

the evaporation of sugar solutions.

To this end it is the main and primary object of the invention to provide a portable evaporator which is designed especially for use at the farm of small planters of sugar too remote from rail or water transportation for shipping their cane to large factories by providing a simple yet efficient evaporator for such use.

With these and many other objects in view, which will readily appear as the nature of the invention is better understood, the same consists in the novel construction, combination, and arrangement of parts hereinafter more fully described, illustrated, and claimed.

In the accompanying drawings, Figure 1 is a perspective view of a portable evaporator constructed in accordance with my invention. Fig. 2 is a vertical longitudinal sectional view of the same. Fig. 3 is a vertical transverse

sectional view on line x x of Fig. 2.

Referring to the accompanying drawings, A represents an elongated furnace provided at one end with the ordinary fire-box B, hav-35 ing the grate C and ash-pan C' therebeneath, while the opposite end thereof is provided with the ordinary escape-stack D, from which the smoke and other products of combustion escape. The said furnace is mounted upon 40 the front and rear axles E, carrying the wheels F, by means of which the said furnace may be transported readily from one place to another. Supported within said furnace and extending the entire length thereof is the semicircular 45 evaporating-pan G. The said evaporatingpan G has a horizontal bottom g the entire | length thereof, and is also provided with a series of independent partitions H, forming a

ing-chambers I, which evaporating chambers 50 or pans decrease in size from the fire-box of the furnace where the heat is the greatest to the escape end thereof, so as to compensate for the different intensities of heat, which is greatest directly over the grate and fire-box 55 and is the least at the smoke-stack end thereof, at which point is located the shallowest pan. Therefore by such construction and arrangement of evaporating-pan the evaporation is even and the several compartments or 60 chambers have a uniform area of exposed surface, owing to the gradual decrease of heat to which said compartments are subjected. The extreme upper edge of the furnace and the evaporating-pan resting therein is banded by 65 a continuous band L, extending entirely around the same, which not only serves to support the said evaporating-pan in the top of the furnace, but also strengthens and renders more durable the entire structure.

One side and end of the evaporating-pan is provided with an offstanding gutter M, which is designed to receive the skimmings of the juice, which is swabbed while the juice is boiling. It will of course be understood that the 75 fire is the hottest directly under the largest compartment directly thereover and the boiling is therefore most rapid in said compartment. After the juice has been partially boiled in the largest compartment it is dipped 80 therefrom successively into the other compartments to the last small one in which it is finished, cooled, and drawn off through the pipe N, passing through the bottom of the furnace and said smaller compartment; but 85 it will of course be understood that the juice can be transferred from one compartment into the other in any suitable manner.

Having thus described my invention, what I claim, and desire to secure by Letters Pat- 90

ent, is—

Supported within said furnace and extending the entire length thereof is the semicircular evaporating-pan G. The said evaporating-pan G has a horizontal bottom g the entire length thereof, and is also provided with a series of independent partitions H, forming a series of separate and independent evaporat-

: -jl. ·

independent compartments decreasing in size from the fire-box of the furnace to the opposite end, and a strengthening and supporting band encircling the upper edge of the fur-5 nace and the evaporating-pan resting thereon, substantially as set forth.

In testimony that I claim the foregoing as

my own I have hereto affixed my signature in the presence of two witnesses.

THEOGENE E. RICHARD.
