# UNITED STATES PATENT OFFICE.

JAMES SUGDEN AND WALLACE J. L. SANDY, OF LONDON, ENGLAND, ASSIGN-  
ORS TO CHARLES HENRY FREEDMAN, FRANK WEST SUTER, AND HAR-  
RINGTON WYMAN, OF SAME PLACE.

## ELECTRIC-ARC LAMP.

SPECIFICATION forming part of Letters Patent No. 490,992, dated January 31, 1893.

Application filed July 13, 1892. Serial No. 439,913. (No model.) Patented in France June 28, 1892, No. 222,653, and in England  
April 13, 1892, No. 7,095.

*To all whom it may concern:*

Be it known that we, JAMES SUGDEN, resid-  
ing at 99 Wyndham Road, Camberwell, and  
WALLACE JAMES LAMBERT SANDY, residing  
5 at 41 Choumert Road, Peckham, London, Eng-  
land, citizens of England, have invented cer-  
tain new and useful Improvements in Elec-  
tric-Arc Lamps, (for which we have obtained  
patents in England, No. 7,095, dated April 13,  
10 1892, and in France, No. 222,653, dated June  
28, 1892,) of which the following is a specifi-  
cation.

Our invention relates to the mechanism for  
automatically feeding the carbons or other  
15 electrodes of electric arc lamps and regulat-  
ing their distance as we shall describe refer-  
ring to the accompanying drawing which is a  
vertical section partly in elevation of a lamp  
according to our invention.

20 The lower carbon A is clamped by a setting  
screw A' in the socket head A<sup>2</sup> of a tube A<sup>3</sup>  
which passes through the tubular core of an  
electro magnet A<sup>4</sup> having its coil in the lamp  
circuit. To the underside of the socket A<sup>2</sup> is  
25 fixed an iron washer A<sup>5</sup> constituting an arma-  
ture which is attracted when the electro mag-  
net A<sup>4</sup> is excited and is drawn down in oppo-  
sition to a spring A<sup>6</sup>, but when A<sup>4</sup> is inert is  
pushed up by the spring as far as permitted  
30 by a nut A<sup>7</sup> acting as a stop. The electro  
magnet A<sup>4</sup> is itself carried by the rods B B  
which with a casing C to which they are se-  
cured constitute the framing of the lamp. The  
upper carbon D is held in a split spring socket  
35 D' which is pivoted by a ball pressed by a  
spring D<sup>2</sup> within a hollow plunger or piston  
D<sup>3</sup> which fits but not tightly the interior of a  
tube D<sup>4</sup> which is closed at the top. Spring  
blades D<sup>5</sup> project down from the piston D<sup>3</sup>  
40 and rub against the interior of the tube D<sup>4</sup>  
so as to insure conducting electrical contact  
therewith. One side of the carbon D bears  
against the periphery of a grooved roller E;  
facing its other side is the end of a screw F

which by means of a milled nut F' can be ad- 45  
justed nearer to or farther from the carbon.  
The screw F is held in one arm G' of a bell  
crank lever pivoted at G; another arm G<sup>2</sup> car-  
ries an armature G<sup>4</sup> to an electro magnet H  
and has its stroke limited by an adjusting 50  
screw G<sup>5</sup>. The third arm G<sup>3</sup> of the lever car-  
ries an adjustable counterweight G<sup>6</sup>. The coil  
of the electro magnet H, as well as that of A<sup>4</sup>  
is in the lamp circuit which is so arranged  
with the parts suitably insulated, that the cur- 55  
rent from the one leading in wire passes  
through the coil of H to the casing C tube D<sup>4</sup>,  
blades D<sup>5</sup> piston D<sup>3</sup> to the upper carbon D,  
then through the arc to the lower carbon A,  
through the coil of A<sup>4</sup> up one of the rods B to 60  
the other leading in wire.

The action of the lamp is as follows:—The  
points of the two carbons A and D, being in  
contact, A being then held up by the spring A<sup>6</sup>  
when the lamp is put in circuit, both the mag- 65  
nets A<sup>4</sup> and H are excited. The one A<sup>4</sup> attracts  
its armature A<sup>5</sup> lowering the lower carbon A,  
while the other H attracts its armature G<sup>4</sup> and  
thereby causes the point of the screw F to press  
against the upper carbon D, and to prevent it 70  
from descending, thus by the separation of the  
point of the carbon the arc is struck. After-  
ward when owing to consumption of the car-  
bons the resistance of the arc increases, the  
weight G<sup>6</sup> overcomes the attraction of the ar- 75  
mature G<sup>4</sup> and the point of F is withdrawn  
from the carbon D, which is thus permitted to  
descend, but it can only descend very slowly,  
because it takes time for air to leak past the  
piston D<sup>3</sup> to the space in the tube above it. 80  
As the upper carbon is thus permitted to ap-  
proach the lower carbon, the resistance is less-  
ened, the armature G<sup>4</sup> is again attracted, and  
the carbon D is again held stationary by the  
pressure of the screw F. The electro magnet 85  
H might have its coil in a shunt to the lamp  
circuit, the lever carrying the screw F being  
arranged so that the carbon should be re-

leased when the armature G<sup>4</sup> was attracted owing to greater current in the shunt resulting from greater resistance of the arc.

5 Having thus described the nature of our invention and the best means we know for carrying the same into practical effect we claim:—

10 The combination in an electric arc lamp, of a lower electro magnet having a spring supported armature to which the lower carbon is attached, with a closed air tube, a piston within the closed air tube to which the upper carbon is attached, a roller at one side of the upper carbon, and an electro magnet having an armature lever the arm of which is located at  
15 the opposite side of the upper carbon and acts in connection with the roller as a brake to hold the upper carbon stationary, substantially as described.

In testimony whereof we have signed our

names to this specification, in the presence of 20 two subscribing witnesses, the 28th and 30th days of June, A. D. 1892.
