HARRY H. RUMBLE, OF NORFOLK, VIRGINIA, ASSIGNOR OF ONE-HALF TO J. FRANK EAST, OF SAME PLACE.

MOSQUITO-NET FRAME.

SPECIFICATION forming part of Letters Patent No. 506,551, dated October 10, 1893.

Application filed June 30, 1893. Serial No. 479,246. (No model.)

To all whom it may concern:

Be it known that I, HARRY H. RUMBLE, residing at Norfolk, in the county of Norfolk and State of Virginia, have invented a new and useful Improvement in Mosquito-Net Frames, of which the following is a specification.

My invention is an improvement in frames for supporting mosquito nets seeking among to other improvements to provide a simple, light and inexpensive construction by which to support the net properly over the bed when in use and which will enable the net to be easily lifted and adjusted back out of the way when it is desired to make the bed.

The invention consists in the novel construction and combinations of parts as will be hereinafter described and pointed out in the claims.

view of my improvement applied to a bed. Fig. 2 is a side view showing the edge frame and thrown up vertically into position to hold the net entirely off the bed. Fig. 3 illustrates one of the corner joint pieces. Fig. 4 illustrates that the connection between the head and side rods of the odge frame.

side rods of the edge frame. As shown in the accompanying drawings I employ two frames A and B, which for con-30 venience of reference I shall term respectively the top or canopy frame and the edge or base frame. The top frame A is formed with the standards α , the horizontal arms α' extended from the upper ends of the stand-35 ards a and the connecting rod a^2 , joining the front ends of the arms a'. The standards are connected to the arms a' and the latter to the connecting rod a^2 by means of corner pieces C shown in detail in Fig. 3 and con-40 sisting of thimbles C' arranged at right angles to each other and joined by a connection C², preferably rounded and curved as shown. These thimbles C' receive the ends of the rods and the latter are clamped by means of thumb 45 screws C³, as shown. In practice I arrange the screws C³ upon the side of the thimble opposite that upon which the net rests so that

the net will not be caught by the screw heads.

Strut braces D are interposed between the

braces may be secured in any suitable man-

50 angle of the standards a and arms a'. These

ner, a simple construction being that shown in which the braces have spurs d at their ends which are pressed into the standard and arms as will be readily understood. A wire A' ex- 55 tends between the corner pieces which unite the standards and arms and forms a support for the net at such point. The standards aare secured to the head board by fitting them in eyes or sockets E upon the back of the 60 head board. To permit a vertical adjustment of the top frame I provide the standards with a vertical series of holes to receive pins e so the standards may be held at any desired height. The parts a a' and a^2 of the frame A 65 are preferably formed of some strong light wood as bamboo or cane. The edge frame B is formed with the head bar F side bars G and end cross bar H. The bar F is preferably metal and the bars G and H of light 70 wood such as is mentioned above. I connect the bars G and H by corner pieces C, such as before described and I provide stops to limit the downward movement of the frame, such stops being shown as legs I depending from 75 the bars G and arranged to rest upon the floor when the frame B is lowered.

The head bar F which may preferably be adjustable in length by means of set screws is provided between its ends with the crank 80 arm f and is journaled to the bed in rear of the head board; it may preferably be on a level with the lower edge of the bed rails. This journal is preferably secured by means of brackets J, secured to the bedstead and 85 having rings j to receive the shaft like head bar, as shown most clearly in Fig. 1. At its ends the head bar F is provided with arms K extended at right angles and having collars L L secured to them by bolts. These 90 collars receive the ends of the side bars G and are provided with thumb screws on the under side by which to clamp the said bars in place. A spring M is secured at one end to the crank arm f and is secured at its other 95 end to the bedstead. In securing said spring to the bedstead it is preferred to provide it with a hook m so it may be caught into engagement with a bed slat and the spring may be suitably connected with the crank arm to roo enable its tension to be adjusted. The purpose of this spring is to assist in lifting the

edge frame, it serving as a counterbalance spring so the edge frame and the net may be easily lifted in the use of the improvement. The net is thrown over the top frame and bed and extends around the bed and is suitably secured to the cross bar of the canopy frame and the cross bar H of the edge frame B. This may be by pinning it to said frames or otherwise as desired. To get into or out of bed it is only necessary to lift the loose side edges of the net to a sufficient height.

When it is desired to adjust the net entirely back from the bed it is only necessary to throw the frame B back to the position indicated in dotted lines Fig. 2 when the net will fall in graceful folds from the outer edge of the canopy to the head bar F, leaving the

bed free, as seen in Fig. 2.

It will be seen that the application of the two frames A and B to the bed is simple so they may be conveniently applied to and removed from the bed. It will also be noticed that the bars of the two frames are so united that they may be easily detached and stored in a small space, when not in use. A turn button N is pivoted to the head board and is adapted at its swinging edge to engage one of the side bars G of the edge frame, when the latter is turned vertically upward, to second the said parts in such adjustment.

Having thus described my invention, what

I claim is—

1. In a mosquito net frame, an edge frame extending entirely around the bed outside of and approximately on a level with the lower edge of the rails thereof whereby it may carry the net positively to a point below the bed surface and hinged or journaled at the back of the head thereof and adapted for use sub-to stantially as set forth.

2. In a mosquito net frame, an edge frame extending along the sides and foot of the bed

and having a hinged or journaled shaft at the head thereof combined with a counterbalance spring connected with said shaft and 45 adapted to assist in raising the frame, substantially as set forth.

2 Transpassorite

3. In a mosquito net frame, an edge frame extended outside of and along the sides and foot of the bed and hinged or journaled at 5c the head thereof, whereby to encircle the bed substantially as shown and provided with a stop whereby to limit the downward movement of the frame, substantially as set forth.

4. In a mosquito net frame, an edge frame 55 comprising the head bar having a crank arm, and the side and foot bars, combined with the bed to which said head bar is journaled and the spring connecting the crank arm of said head bar with the bed, substantially as 60

set forth.

5. An improvement in mosquito nets consisting of the top or canopy frame fixed normally to and extended forward from the head board and the edge frame extended along the 65 sides and foot of and embracing such portions of the bed and hinged or journaled at the head thereof whereby its foot bar may be swung up over the fixed top or canopy frame, all substantially as set forth.

6. The improvement in mosquito net frames, substantially as described, consisting of the top or canopy frame, the edge frame fitting around the bed and having its head bar journaled thereto and provided with a 75 crank arm, a spring connecting said crank arm with the bed, and legs depending from said frame and forming stops to limit the downward movement thereof, all substantially as and for the purposes set forth.

HARRY H. RUMBLE.
