## United States Patent Office.

CASWELL LEE LEONARD AND ALBERT BEVER, OF VEEDERSBURG, INDIANA.

## CHURN.

SPECIFICATION forming part of Letters Patent No. 528,000, dated October 23, 1894.

Application filed July 21, 1894. Serial No. 518,172. (No model.)

To all whom it may concern:

Be it known that we, CASWELL LEE LEON-ARD and ALBERT BEVER, citizens of the United States, residing at Veedersburg, in the county of Fountain and State of Indiana, have invented certain new and useful Improvements in Churns, of which the following is a specification.

Our invention refers particularly to an osto cillating churn having for its object the production of an oscillatory churn whereby the movement of the churn is impeded, stopped and reverted at each complete oscillation by means of suitably bent springs, a pair of 15 pivots, and an actuating lever mechanism, and consists in the peculiar construction, combination, and arrangement of the several parts as will be fully pointed out in the following description and claim.

Referring to the accompanying drawings forming a part of this specification, Figure 1 is a top plan view of our churn. Fig. 2 is a elevation. Fig. 4 is a side plan view of the 25 leg casting 5'. Fig. 5 is a plan view showing the inner side of the lever handle 7 and lever casting 7'. Fig. 6 is a detail view of the little lever casting pivot 72.

Like numbers of reference indicate corre-30 ponding parts throughout the several views.

In the embodiment of our invention we use a rectangular, oscillating churn-box 1, a pair of pivots 2 and 2' rigidly mounted at the sides of the churn-box, a pair of V-shaped 35 legs 3 supporting the churn-box and pivots, a pair of bent springs 4 securely mounted upon the inner sides of the V-shaped legs, a pair of castings 5 and 5' securely mounted upon the upper ends of the legs, an X-shaped 40 casting 6 bracing the legs, and an oscillating lever mechanism 7 for actuating the oscillatory churn-box 1.

Centrally upon the sides of the rectangular churn-box 1 are rigidly mounted its pivots 2 45 and 2' standing out laterally therefrom and working in suitable reciprocal apertures in the castings 5 and 5' of the V-shaped legs 3, the supporting frame-work of the churn, the V-shaped legs 3 being braced near the 50 bottom by an X-shaped casting 6.

1' refers to a rectangular lid for being re-

moved so as to pour milk or cream into or out of the churn and is provided with a small circular glass 12 for viewing the interior of the churn-box while churning. The lid 1' is se- 55 curely held in position on the churn-box by means of a hinged bar 13 hinged at 14 and adapted to be securely fastened at the free end to the churn-box casting 15 by means of a removable thumb-screw 16.

15 refers to a pair of castings at the ends of the churn-box for rigidly holding it together.

The bent springs 4 being suitably secured to the V-shaped legs are coiled about one and a half times around and bent parallel with 65 the leg to which each is secured and then curved inwardly at the lower end toward the churn-box so as to hook in the staples 17 at the sides of the churn-box to impede, stop, and revert the oscillations of the churn.

6 indicates an X-shaped casting rigidly bracing the lower ends of the V shaped legs.

The V-shaped legs are suitably and sefront elevation of the same. Fig. 3 is a side | curely mounted at the upper ends in a pair of castings 5 and 5' having suitable recipro- 75 cal apertures for the reception of the pivots 2 and 2'. The casting 5' is formed with a segment shaped frame 52 supporting the adjustable, oscillating lever mechanism 7 for operating the churn. The oscillating lever 80 mechanism comprises a lever handle 7, a segment shaped lever casting 7', a small casting pivot 72 for the segment shaped lever casting, and a through bolt 7<sup>3</sup> for securing the casting pivot 7<sup>2</sup> securely upon the sup- 85 porting frame 5<sup>2</sup>.

> 74 refers to a small cog-wheel rigidly fixed upon the outer end of the pivot 2' so as to mesh with the section of cogs 75 on the segment shaped lever casting 7'.

The segment shaped lever casting 7' is provided on the inner side with a section of cogs 75 adapted to mesh with the small cogwheel 74 rigidly fixed upon the outer end of the pivot 2' and impart to said cog-wheel, 95 pivot, and churn-box one complete revolution at a single stroke of the lever mechanism. The lever handle 7 is securely screwed to the segment shaped lever casting 7' and the casting pivot 72 upon which said casting 100 oscillates, is adapted to be set at any point in its reciprocal circular opening 53 in the seg-

ment shaped supporting frame 52 and securely bolted there by the through-bolt 73. This peculiar construction of the adjustable oscillating lever mechanism and its support-5 ing frame enables the operator to set the operating lever mechanism in a horizontal or a vertical position or at any point between said positions. It will be observed that the bent springs impede and stop the churn-box at to about a complete revolution and revert its movement in the opposite direction successively and consecutively as it about completes a revolution in either direction, imparting to the churn-box an automatic rocking or os-15 cillatory movement, effectually working its contents in every direction.

Having thus fully described our invention and shown the operation thereof, what we claim as new, and desire to secure by Letters

20 Patent, is—

A churn having a pair of V-shaped legs securely braced near the bottom by an X-shaped casting and mounted at their upper ends in a pair of castings provided with suitable reciprocal apertures for the reception of the churn-box pivots, a rectangular churn box having a removable lid held securely in position thereon by means of a hinged bar having a thumb-screw at its free outer end adapted to be screwed into a reciprocal opening of the casting at the upper end of the churn box, a pair of pivots mounted centrally at the sides of the churn-box standing out

laterally therefrom and adapted to work in reciprocal openings of the V-shaped leg cast- 35 ings, having a small cog-wheel rigidly fixed upon the outer end of a pivot adjacent the adjustable, oscillatable lever mechanism so as to be actuated by said mechanism, a segment shaped supporting frame having a cir- 40 cular reciprocal opening for the reception of the movable casting pivot of the lever mechanism, and an adjustable, oscillatable lever mechanism comprising a lever handle, a segment shaped lever casting rigidly fixed to 45 the lever handle and mounted upon a movable casting pivot adapted to be secured rigidly to the segment shaped supporting frame by a through-bolt and a section of cogs on the inner side of the segment-shaped cast- 50 ing adapted to mesh with the small cog-wheel of the pivot so as to impart to it a complete revolution at a single stroke of the lever mechanism, and a pair of bent springs mounted rigidly upon the inner side of the 55 V-shaped legs adapted to impede and to stop the rocking oscillatory churn-box and to revert its movement in an opposite direction successively and consecutively at about a complete revolution in either direction, sub- 60 stantially as specified.

CASWELL LEE LEONARD.
ALBERT BEVER.
