## A. S. WAITZFELDER. DRESS STAY.

No. 562,443.

Patented June 23, 1896.

Suspave Diteriole. Mille & Smith

Month of Hait felder

By Sniesen Skuaut

## UNITED STATES PATENT OFFICE.

ALBERT SIDNEY WAITZFELDER, OF NEW YORK, N. Y., ASSIGNOR TO THE KURSHEEDT MANUFACTURING COMPANY, OF SAME PLACE.

## DRESS-STAY.

SPECIFICATION forming part of Letters Patent No. 562,443, dated June 23, 1896.

Application filed November 28, 1894. Serial No. 530,239. (No model.)

To all whom it may concern:

Beit known that I, Albert Sidney Waitz-Felder, a resident of the city, county, and State of New York, have invented an Improved Dress-Stay, of which the following is

a specification.

My invention relates to dress-stays or garment-distenders, and has for its object to produce a new and useful braided dress-stay or garment-distender having a stiff body, of flat strips, overlaid with yarns or threads running uninterruptedly in straight lines from edge to edge, and which are braided at the outer edges of the strips and filled with longitudinal threads, known as "underwarps," between such strips in such a manner as to produce the character of edging known as "soutache" between the strips.

To this end my invention consists in the 20 article of manufacture hereinafter described

and claimed.

My invention will be understood by referring to the accompanying drawings, forming part of this specification, in which—

Figures 1 and 2 are detail plan and transverse sectional views, respectively, of a portion of a dress-stay or garment-distender

made according to my invention.

Heretofore in the manufacture of hat-wire 30 and the like it has been customary to cover a flat or round wire with threads or yarns by braiding the same over the entire surface of the wire, so as to produce the effect of a continuous covering of fabric. By my invention 35 I cover the faces of two flat resilient strips, such as spring-steel, with yarns or threads running in straight lines across both faces of each strip from edge to edge, and braided at the edges only, to produce a reticulated or 40 open effect upon the body or faces of the strips, and by bringing two longitudinal or underwarp threads of greater diameter than the thickness of the resilient strips adjacent to the inside edges of the strips and braiding 45 the threads around and between them as well as between a strip and its next adjacent underwarp to produce an edging known as "soutache" between the flat strips, and a braided beading without a filling-thread on 50 the outer edge of the stay or distender.

In the drawings, H H' represent two strips of resilient material, such as spring metal, which have overriding braiding-threads e, extending in an open-work manner in straight lines across both faces thereof without inter- 55 locking. These threads are interbraided at the outer edge of each of the strips H H' to form a close beading g g and are interbraided with longitudinal filling-threads or underwarps of greater diameter than the thickness 60 of the dress-stay or of the resilient strips thereof at  $d^2$   $d^2$ , so as to form what is known as a "soutache" edge between the strips. By this construction means are provided by the underwarps of the soutache for guiding 65 the needle in securing the stay to the garment to which it is attached and at the same time forming by the soutache and braided beading edges secure means by which the article can be attached to the garment with- 70 out exposing the attaching-threads, thereby providing an efficient article which is cheap in construction, can be readily attached, and presents an ornamental appearance.

I am aware that it is not broadly new to 75 make a dress stay or distender with an openwork covering. I am also aware that it is not broadly new to employ a single flat resilient strip in distenders, and such I do not elaim: but

claim; but

What I do claim, and desire to secure by

Letters Patent, is—

A dress stay or distender comprising two flat metallic resilient strips, a closely-braided beading on the outer edge of each of said 85 strips, all the threads constituting the said beading extending in straight lines across and overriding the faces of said strips and forming an open-work series of parallel strands which are interbraided between the 90 flat strips with two fibrous warp-strands of greater diameter than the thickness of the flat resilient strips to form a close edging, substantially as described.

ALBERT SIDNEY WAITZFELDER.
