PHILLIP HAMM AND JOHN WM. PERTZ, OF ELWOOD, INDIANA.

BOTTLE-WASHER.

SPECIFICATION forming part of Letters Patent No. 565,456, dated August 11, 1896.

Application filed January 4, 1896. Serial No. 574,357. (No model.)

To all whom it may concern:

Be it known that we, PHILLIP HAMM and JOHN WM. PERTZ, citizens of the United States, residing at Elwood, in the county of Madison, State of Indiana, have invented certain new and useful Improvements in Bottle-Washing Machines; and we hereby declare the following to be a full, clear, and exact description of the same, reference being had to the accompanying drawings, in which—

Figure 1 is a plan view of a machine embodying our invention, showing the position of the parts when not in operation. Fig. 2 is a longitudinal central section of the same 15 on the line x x, Fig. 1. Fig. 3 is a plan view similar to Fig. 1, the parts being in position they occupy when the machine is in operation, a bottle being shown in position on the nozzle of the brush-guide and the brushes 20 only partially advanced, the dotted lines indicating the position of the brushes when fully advanced so as to scrub the bottom of the bottle. Fig. 4 is an enlarged sectional view of the brushes and brush-guide. Fig. 25 5 is an end view of brush-guide, looking in i the direction of the arrow, Fig. 4. Fig. 6 is a view of the end of one of the brush-stems in elevation and of the brush thereon in longitudinal section, the section being at right 30 angles to that of Fig. 4; and Fig. 7 is an enlarged longitudinal central section of the water-supply valve.

Like symbols refer to like parts wherever

they occur.

Our invention relates to bottle-washing machines, and wherein the construction hereinafter described is applicable to bottle-washing machines in general no limitation to machines for washing any special form or char-40 acter of bottle is intended to be imposed; but inasmuch as difficulty has heretofore been experienced in washing by machinery that class of bottles (such as soda or pop bottles) which contain an included and retained stop-45 per, (such as the "Hutchinson" or stem-stopper,) special features of construction have been added to facilitate the cleaning of that class of bottles by means of brushes, and in addition to the general claims, special claims 50 thereto are hereinafter made.

The first feature of our invention therefore embraces the combination, with a rotat-

able cylinder, shell, or chamber, of a perforated head, piston, or brush-carrier, and a hollow stem on which the brush-head or piston is journaled, said brush-head or piston and stem longitudinally movable in the cylinder, and the brush-head capable of rotating with said shell or cylinder, and on the hollow piston-stem, whereby the brush may be rotated by the cylinder or shell and be advanced or retracted by the hollow stem, and an evenly balanced, efficient, and durable machine is obtained.

A second feature of our invention embraces 65 the combination, with the revolving shell and longitudinally movable water-pipe, of a spring-pressed counterweighted clutch, a spring-pressed valve for the water supply, and means for moving the water-supply valve 70 from the spring-pressed counterweighted clutch, whereby the said devices are simultaneously thrown into and out of operation.

A third feature embraces the combination, with the brushes, of a brush-guide having 75 means for securing and retaining a stemstopper so that it shall be held out of the way of the moving brushes during the operation thereof.

There are other minor features of invention, all as will hereinafter more fully appear.

We will now proceed to describe the preferred form of our machine more specifically, so that others skilled in the art to which it appertains may apply the invention.

In the drawings, A indicates a suitable bedplate provided with uprights, pedestals, or pillow-blocks a a, on which is journaled a rotatable shell or cylinder 1, and having a third upright b, which forms a guide or support 90 for the hollow stem or water-pipe 10. Secured to (or formed on) the rotatable shell or cylinder at suitable distances apart are limitcollars 22, which prevent the endwise play or movement of the rotatable cylinder 1. 95

3 indicates a belt-pulley loosely journaled on the cylinder 1 between pillow-blocks a a, adjacent to which is a collar 4, which may be formed on and moved with the rotatable cylinder 1, or it may be secured thereto by a set-screw 4^a, as preferred, and from said collar 4 projects a pin 5, which passes through a hole or perforation in the sliding friction-clutch 6, so that said sliding clutch is also caused to ro-

tate with the cylinder or shell 1. The sliding clutch 6 is coned at the end next the loose pulley 3, and said loose pulley 3 is correspondingly recessed on its side to receive the 5 cone end of the clutch, thus forming the usual friction-clutch, instead of which any approved form of clutch may be employed. Said sliding clutch is provided at its opposite end with a collar 6° or equivalent means for ro engaging a shifting mechanism, and is recessed for the reception of a spring 6^b or equivalent means for forcing the clutch 6 into engagement with the loose pulley 3.

7 indicates a shifting-rod having at one end 15 a hook 7^a or equivalent means for engaging the friction-clutch 6, said shifting-rod being passed loosely through a cross-head 8 and provided with an adjustable nut 7^b or equivalent means of engaging said cross-head 8, the 20 other end of said shifting-rod terminating in or provided with an arm 7°, adapted to engage the valve-stem 9° of spring-pressed valve 9a, which controls the water supply of the machine. It will be noted that arm 7° is pro-25 vided with a set-screw 7^d, which strikes the valve-rod 9°, and the same or its equivalent may be used to adjust the movement of valve 9^a and regulate the water supply.

9 indicates the shell or casing of the water-30 supply valve 9a, which casing may be attached to or supported on the upright b, and from which a flexible hose 9b leads to the hollow stem 10 or water-supply pipe of the

machine.

35 Connected to the cross-head 8 above referred to is a cord or chain 8a, which passes over pulleys 8^b 8^c, and to which is attached a weight 8d, so that as the cross-head 8 engages 40 shifting-rod 7 passes loosely through crosshead 8,) and shifting-rod 7 engages springpressed sliding clutch 6, through the medium of hook 7a, it will be noted that said clutch 6 is pressed by spring 6b in one direction, and

45 at certain times counterweighted in the opposite direction. As the arm 7° of shiftingrod 7, through the medium of set-screw 7^d, engages the stem 9° of spring-pressed watersupply valve 9a, it will be further noted that 50 the water-supply valve is alternately spring

pressed in reverse directions.

10 indicates the water-supply pipe of the machine, which is secured in the cross-head 8 by a set-screw 10°, or its equivalent, so as 55 to move therewith or be moved thereby, and said cross-head 8 is connected by a set-screw 8°, or otherwise, with the hand (or operating) rod 11, so as to give the operator, (who is stationed at the nozzle end of the machine,) to through said rod 11 and cross-head 8, complete control of the machine, to start or stop

it, simultaneously turn on or off the water,

and project or retract the brushes.

The water-supply pipe 10 passes through 65 guide-pedestal or support b, and at one end is connected with the water supply by a flexi-

ble pipe 9b, as hereinbefore pointed out. The other end of said water-pipe (which is arranged in the axis of rotation of the cylinder) enters the rotatable cylinder 1 through a 70 suitable stuffing-box or cylinder-head 12, and by means of a collar 10^a and threaded sleeve 10^b, or otherwise, is loosely connected with a perforated brush-head 13 or piston, for which the supply-pipe constitutes a hollow 75 stem, so that said brush-head or piston while compelled to move longitudinally with the hollow stem or water-supply pipe 10 is capable of rotation on said stem or pipe and with the rotatable cylinder 1. Secured to said 80 brush-head or perforated piston 13 are brushstems 13^a 13^a, preferably spring-steel strips, whose outer ends terminate in flexible brushes 13^b 13^b, or wipers, which are usually of rubber, and secured to the stems by means of sockets 85 which are slipped over the irregularly-shaped ends of the stems 13^a, as shown in sectional view, Fig. 6.

Secured to that end of rotatable cylinder 1 from which the brushes 13^b 13^b project is 90 a brush guide and nozzle 14, having a plurality of slots 14^a for the passage and guidance of the brushes 13^b 13^b, between which slots is a notch recess or pocket 15 for the reception of the stem of a stopper, (see s, Fig. 3,) and 95 the stopper-stem will, without other provision, be retained therein during the rotation of the cylinder and the operation of brushes 13^b 13^b. Sprung upon the nozzle or projecting end of brush-guide 14 is a rubber sleeve 100 or washer 16, to close against the mouth of the bottle and prevent the escape of water during the operation of the machine.

The operation of the machine is as follows: nut 7^b, which is fast on shifting-rod 7, (though | In case of a bottle having an included or re- 105 tained stopper, the bottle is inverted until the stem of the stopper projects, and the end of the stem is inserted in the notch or recess 15 in the brush-guide, the mouth of the bottle being held over the nozzle of the guide and 110 against the washer 16. The bottle being in position as aforesaid, the hand or operating rod 11 is drawn forward, (see Fig. 3,) which in turn, through cross-head 8, forces the watersupply pipe 10 (or hollow piston-stem) into cyl-115 inder 1 and moves the brush-head 13 forward in the cylinder 1, thus projecting the brushes 13b, which brushes pass to both sides of the securely-held stopper S, (see Fig. 3,) and by the spring action of stems 13^b 13^b are brought 120 in contact with the sides of the bottle. As the brush-head 13 continues to advance, the brushes are carried to the bottom of the bottle, and, being bent or flexed, meet at the center and thus perfectly cleanse the bottom as well 125 as the sides of the bottle. As the brush-guide 14 is attached to and rotates with the cylinder or shell 1, and the brush-stems 13a, which are attached to the brush-head 13, (or piston,) pass through the brush-guide 14 eccentrically, 130 (or off the axis,) the brushes 13b, brush-stems 13^a, and head 13 will revolve with cylinder 1.

565,456

Simultaneously with the advance of watersupply pipe 10 and cross-head 8, as above noted, the sliding clutch 6 is thrown into engagement with loose pulley 3 by the operation 5 of spring 6b, and the cylinder 1 is set in motion, while at the same time and by operation of said spring 6^b the shifting-rod 7 is drawn forward so that arm 7° on the end thereof, through the medium of set-screw 7^d, strikes the 10 stem 9° of water-supply valve 9°, compresses the spring thereof, forces the valve 9a off its seat, and thus turns on the water, which passes by supply-pipe 10 (or hollow piston-rod) through the perforated brush-head 13, (or pis-15 ton,) cylinder 1, and slotted brush-guide 14 to the bottle to be washed.

When the bottle has been sufficiently washed, the hand or operating rod 11 is released or pushed back, permitting or causing 20 the counterweighted cross-head 8 and attached supply-pipe or hollow stem 10 to recede, which carries with it the brush-head 13 and withdraws the brushes 13^b 13^b from the bottle and into the brush-guide 14, and when 25 the cross-head 8 has nearly completed its retreat, it strikes nut 7^b on shifting-rod 7, which takes up and carries with it said rod 7 and fork 7^a, compressing spring 6^b, and withdrawing sliding clutch 6, thus releasing loose pul-30 ley 3 and stopping the rotation of cylinder 1. As soon as the recession or backward movement of shifting-rod 7 begins, the arm 7° on the end thereof releases the valve-stem 9° of watersupply valve 9^a, and the spring thereof, aided 35 by the pressure of the water, immediately closes said valve and shuts off the water from the machine.

Having thus described our invention, what we claim, and desire to secure by Letters Pat-

40 ent, is—

1. In a bottle-washing machine, the combination with a rotatable shell or cylinder, of a perforated brush-head or piston, longitudinally movable therein, and a hollow stem, on 45 which the brush-head or piston is journaled, substantially as and for the purposes specified.

2. In a bottle-washing machine, the combination with a rotatable shell or cylinder pro-50 vided at one end with a brush-guide, of a longitudinally-movable brush-head arranged in said shell or cylinder and provided with brushes, and a longitudinally-movable water-supply tube arranged in the axis of the 55 rotatable cylinder and loosely connected with the brush-head; substantially as and for the purposes specified.

3. In a bottle-washing machine, the combination with a rotatable shell or cylinder, 60 bearings therefor, suitable brushes, and a water-supply pipe, of a clutch for transmitting motion to the rotatable cylinder or shell, a valve for controlling the water-supply pipe, and means for opening the water-supply valve from the clutch; substantially as and for the 65

purposes specified.

4. In a bottle-washing machine, the combination with a rotatable shell or cylinder, bearings therefor, suitable brushes, and a water-supply pipe, of a spring-pressed clutch for 70 transmitting motion to the rotatable cylinder, a spring-pressed water-supply valve, and an interposed shifting device whereby the clutch when released is automatically operated and operates or opens the valve of the water-sup- 75 ply pipe; substantially as and for the pur-

poses specified.

5. In a bottle-washing machine, the combination with a rotatable shell or cylinder having suitable bearings and provided with a 80 brush-guide, of a brush-head longitudinally movable therein and provided with suitable brushes, an axially-arranged longitudinallymovable stem or water-supply pipe to which the brush-head is loosely connected, a loose 85 pulley and a spring-pressed clutch mounted on the rotatable cylinder, a spring-pressed valve for the water supply, and a shifting-rod arranged to be actuated by the clutch and to actuate the water-supply valve; substantially 90 as and for the purposes specified.

6. In a bottle-washing machine, the combination with a rotatable cylinder or shell, bearings therefor suitable brushes and a water-supply pipe, of a spring-pressed and coun- 95 terweighted clutch for transmitting motion to the rotatable cylinder, a spring-pressed valve for the water supply, and means for moving the water-supply valve from the spring-pressed counterweighted clutch; sub- 100 stantially as and for the purposes specified.

7. In a bottle-washing machine the combination with a suitable brush, of a brushguide having a slot for the brush and provided with means for holding a bottle-stop- 105 per; substantially as and for the purposes

specified.

8. In a bottle-washing machine, the combination with a movable brush, of a nozzle and brush-guide provided with a slot or passage 110 for the brush, and adjacent thereto a recess to receive the stem of a bottle-stopper; substantially as and for the purposes specified.

9. A brush-guide for bottle-washing machine, said brush-guide having a plurality of 115 slots for the passage of the brushes, and a center recess to receive the stem of a stopper, substantially as and for the purposes specified.

In testimony whereof we affix our signa- 120 tures, in presence of two witnesses, this 2d day of January, 1896.
