DOUGLAS VICKERS, ARTHUR TREVOR DAWSON, AND GEORGE THOMAS BUCKHAM, OF SHEFFIELD, ENGLAND, ASSIGNORS TO VICKERS SONS & CO., LIMITED, OF SAME PLACE.

FIRING MECHANISM FOR BREECH-LOADING ORDNANCE.

SPECIFICATION forming part of Letters Patent No. 610,110, dated August 30, 1898.

Application filed November 9, 1897. Serial No. 657,991. (No model.) Patented in England May 16, 1896, No. 10,606; in Belgium March 8, 1897, No. 126,799; in France March 8, 1897, No. 264,776; in Spain April 17, 1897, No. 20,528; in Austria April 30, 1897, No. 47/1,524, and in Italy May 8, 1897, XXXII, 44,074.

To all whom it may concern:

Be it known that we, Douglas Vickers, a managing director of Vickers Sons & Co., Limited, ARTHUR TREVOR DAWSON, late lieu-5 tenant, R. N., superintendent of ordnance department, and George Thomas Buckham, engineer, citizens of England, residing at River Don Works, Sheffield, in the county of York, England, have invented certain new and use-10 ful Improvements in Breech-Loading Ordnance and Their Mountings, (for which we have obtained patents in the following countries, viz: Austria April 30, 1897, No. 47/1,524; Belgium March 8, 1897, No. 126,799; France 15 March 8,1897, No. 264,776; Great Britain May 16, 1896, No. 10,606; Italy May 8, 1897, Vol. 32, No. 44,074, and Spain April 17, 1897, No. 20,528,) of which the following is a specification.

Our invention relates to mechanism applied at the breech of a breech-loading gun for firing the charge either by percussion or electrically, as we shall describe, referring to the accompanying drawings.

Figure 1 is a rear elevation of the firinggear according to our invention. Fig. 2 is a
section on line 1 1, and Fig. 3 is a plan. Fig.
3^A is a section on line 2 2 of Fig. 2, and Fig.
3^B is a section on line 3 3 of Fig. 1. Figs. 4,
30 5, and 6 show some of the parts to an enlarged
scale, Fig. 4 being a part transverse section,
Fig. 5 a rera elevation, and Fig. 6 a plan.
Figs. 7, 8, and 9 show a modification of the
firing-gear, Fig. 7 being a rear elevation, Fig.
35 8 a section on the line 4 4 of Fig. 7, and Fig.

9 is a plan.

In Figs. 1, 2, 3, 3^A, 3^B, 4, 5, and 6 the construction is as follows: In and on the sliding bar of a breech mechanism, preferably of the type described in Letters Patent of Great Britain No. 9,780 of 1895, is formed a groove A of varying depth, also an inclined groove A'. B is a firing-hammer pivoted to a slide C by an axis-pin D and having a toe B' engaging in the groove A. A projection B² on the hammer B engages with a firing-spring C³ of any suitable form. Another projection B³ on the hammer B engages with the trig-

ger E when the hammer is cocked for percussion firing. A handle F is fitted to the ham- 50 mer B for cocking it. A pin B4 is fitted and suitably insulated in the boss B⁵ of the hammer B. This pin B4 forms an electric contact for electric firing and a striker for percussion firing and passes through a hole in 55 the slide C. The slide C is retained and guided in a nut G and when in the firing position covers the head of a tube or primer. The nut G is carried on the end of the obturating-bolt G' and is fitted to it by inter- 60 rupted rings. In the front of this nut G is a hole G², through which the pin of the hammer passes to reach the tube or primer. A guide for the slide C is formed by jaws G⁴ and G⁵, projecting downward from the nut G and 65 so arranged as to allow the boss C², formed on the slide C, to move vertically between them. An extractor for ejecting the empty tube or primer is carried in the nut G and consists of two levers H and H', carried on 70 a pin H², fitted in bosses provided on the nut G. Around this pin H² is a torsion-spring H⁴, which actuates the lever H, its one end being connected to the nut G and the other to the lever H. The lever H has on it a pro- 75 jection H³, which engages with the extractorlever H' and is so arranged that on the lever H being forced out it brings the extractorlever H' with it, but is free to return to its original position without it. The torsion-80 spring H⁴ keeps the lever H in a suitable position. On the slide C is a boss C2, which contains the retaining-bolt C⁴. This bolt enters and fits the groove A', the incline of which is so arranged that on the horizontal bar being 85 moved it gives the necessary vertical motion to the slide C and also serves to retain it in the locked position. In the boss C² and round the bolt C⁴ is a helical spring C⁵ to enable the retaining-bolt C4 to be withdrawn from the 90 groove A' when necessary for detaching the firing-gear. The spring C3, which actuates the hammer, is carried in a recess cut in the slide C. The trigger E, for holding the hammer Bin cocked position for percussion firing, 95 is pivoted to the end of the retaining-bolt C4

and is actuated by a double lever-cam E', which allows the trigger to be released from either side or the rear of the gun. A suitable insulated contact-piece is carried in the nut B⁶, which is screwed to the boss on the hammer B and makes an electric contact with the

firing-pin B⁴.

The action is as follows: On the first movement of the sliding bar of the breech mechro anism in unlocking the breech-plug the hammer B is caused to move away from the tube or primer by means of the toe B' being forced outward by the varying depth of the groove A, thus breaking the electric circuit between 15 the firing-pin B4 and the tube and preventing the pin B⁴ from striking the percussion-tube. On the continued movement of the sliding bar the toe is brought out of the groove A and rides on the face of the bar, thus insur-20 ing safety while the breech mechanism is unlocked. At the same time the slide C is moved vertically away from the tube or primer, leaving its end uncovered, by means of the retaining-bolt C^4 being actuated by the groove A'. 25 This vertical movement of the slide C causes the projection C' to engage with the extractorlever H, which in turn forces the lever H' backward, thereby ejecting the tube or primer. On withdrawing the retaining-bolt C⁴ from 30 the groove A' in the sliding bar the slide C can be moved vertically downward and the lock worked without moving the sliding bar of the breech. To cock the hammer B for percussion firing, it is drawn rearward by 35 hand until it is caught by the trigger E, which can be released from either side or rear of the gun.

In Figs. 7, 8, and 9, showing a modification, instead of the swinging hammer B, pivoted 40 on the slide C, we use a sliding hammer C⁷. This hammer C⁷ is suitably insulated in a tube C⁸, which works inside a boss C⁶, formed on the slide C. The hammer is held against an electric tube by means of the helical spring 45 C⁹, which also gives it the percussive force when a percussion-tube is used and is placed around the tube C⁸ and held in position by the screwed cap C¹⁰ at one end and a collar C¹¹, formed on the tube C⁸, at the other. The 50 firing-pin C⁷ has a head C¹² formed on its end bearing against the insulated collar C¹¹ of the tube C⁸. On the end of the tube C⁸ is placed a suitable handle C¹³, which is kept in place by the nuts C^{14} and C^{15} . The head C^{11} of the 55 tube C⁸ has a toe C¹⁶ projecting through and working in a slot in the side of the boss C⁶. The projection C¹⁶ works against an inclined ledge C¹⁷, formed on the nut G. It also forms a sear for engaging with trigger E² when

cocked for percussion firing. The trigger E² 60 is the ordinary form of spring-trigger and is carried in a projecting boss C¹⁸ from the side of the boss C⁶. A suitable electric contact is carried in the nut B⁶, screwed on a boss provided on the nut G. The connection between 65 the contact and the firing-pin is made on the head C¹² of the pin C⁷. The retaining-bolt C⁴ is formed on the outer end in the shape of a ring or loop for withdrawing purposes.

The action is as follows: On the first move- 70 ment of the sliding bar of the breech mechanism in unlocking the breech-plug the head C¹² of the needle C⁷ is caused to move away from the tube or primer by means of the toe C¹⁶ riding up the inclined ledge C¹⁷ of the nut 75 G, thus breaking the electric circuit between the firing-head C^{12} and the tube and preventing the head C¹² from striking the percussiontube. On the continued movement of the sliding bar the toe C¹⁶ continues to ride on the 80 ledge C¹⁷, thus insuring safety while the breech mechanism is unlocked. The movement downward of the slide and action of the extractor is the same as that described in reference to Figs. 1 to 7, inclusive. To cock the head C¹² 85 for percussion firing, it is drawn rearward by hand until it is retained by the trigger E².

Having thus described the nature of this invention and the best means we know for carrying the same into practical effect, we claim—90

1. In firing mechanism for a breech-loading gun, in combination with the breech-plug carrier and its horizontal slide-bar, a hammer having an insulated striker, a spring-trigger, a nut on the obturating-bolt, and a sliding 95 plate thereon adapted to cover and uncover the head of a firing-tube, or primer, and to actuate an extractor, substantially as described.

2. In firing mechanism for a breech-loading 100 gun, in combination with the breech-plug carrier and its horizontal slide-bar, an insulated sliding striker and its spring-trigger, a nut on the obturating-bolt, and a sliding plate thereon adapted to cover and uncover the 105 head of a firing-tube, or primer, and to actuate an extractor, substantially as described,

In witness whereof we have signed our names to this specification, in presence of two subscribing witnesses, this 4th day of October, 110 A. D. 1897.
