UNITED STATES PATENT OFFICE.

JOHN A. SVENSON, OF CHICAGO, ILLINOIS.

STEAM-ENGINE.

SPECIFICATION forming part of Letters Patent No. 640,238, dated January 2, 1900.

Application filed May 6, 1899. Serial No. 715,849. (No model.)

To all whom it may concern:

Be it known that I, John A. Svenson, a citizen of the United States, residing at Chicago, in the county of Cook and State of Illinois, have invented certain new and useful Improvements in Steam-Engines, of which the

following is a specification.

The object of my invention is the production of a steam-engine wherein means are pro-10 vided for diminishing those wastes of steam due to cylinder condensation and to clearancespaces, wherein the danger caused by the accidental presence of non-vaporized water in the cylinder is avoided, wherein simplicity of 15 mechanical structure is combined with a high degree of efficiency, and wherein moving parts and steam-surfaces are made easily accessible for inspection and repair. In the attainment of these objects I have produced an en-20 gine the pistons of which normally are relatively stationary, while the cylinders reciprocate. A steam-receiver incloses said cylinders, and live steam being admitted to all portions of the interior of said receiver en-25 tirely surrounds said cylinders. A valve of peculiar construction admits steam from the receiver to the interior of the cylinders, said valve being automatically operated by an eccentric with valve-rod connections and the 30 motion of said cylinders being imparted by the usual connecting-rods to a crank-shaft of ordinary form.

In the accompanying drawings, Figure 1 is a front elevation of this engine, showing the upper portion upon a vertical central section. Fig. 2 is a side elevation of the same, partly in section. Fig. 3 is a horizontal section on dotted line x x of Fig. 1, and Fig. 4 is a perspective view of the valve mechanism.

Like letters of reference indicate corresponding parts throughout the several views.

In the construction of a steam-engine embodying the improvements hereinbefore outlined I provide a supporting-bed A, having the usual crank-shaft A', the crank-pin A², and the balance-wheels A³. Above the bed A and rigidly affixed thereto is provided the supporting-frame A⁴, and upon this supporting-frame is mounted the receiver B. This receiver is of cylindrical dome form and is secured to a base B' by the bolts B², passing through annular flanges B³ on said receiver

and said base. The receiver B is removed from the base B' to give access to the working parts of the engine by merely taking out 55 these bolts B², and thus breaking only one steam-joint—that between the receiver B and the base B'. A steam-inlet B4 extends inward through the base B' and, turning upward within the walls of the receiver B, is pro- 60 vided at one of its sides with a dischargeopening B5 for the ingress of the live steam, whereby said steam is given a gyratory motion upon its entrance into the receiver B, which motion is calculated to separate the 65 water particles from the steam, and thus prevent the presence of water in the cylinders. The opening B⁵, however, is placed a little distance above the bottom of the receiver to provide a space for the reception of the con- 70 densation, should there be any such, and a drain-cock (not shown) may be provided, if necessary, to remove any water which accumulates in such space. An exhaust-port B⁶ extends from the center of said base B' to the 75 outer side thereof, connecting at its inner end with the exhaust-tube B7, which tube extends upward in the center of the receiver B.

An annular piston C, having the supporting-arms C' and the annular base-ring C2, sur- 80 rounds the exhaust-tube B7 and has a yielding connection with the base B' by means of the compression coil-springs C3, secured by the bolts C4, upon which said springs are mounted. These springs C³ are intended to 85 restore the piston C to its normal position, the pressure of the live steam within the receiver B against the under face of said piston being sufficient to hold it in its upper position. Should a blow fall upon the piston C- 90 as, for example, the shock which would be caused by the presence of a considerable quantity of water within the lower cylinder during the operation of the engine—the piston C yields, becoming a relief-valve of a size equal 95 to the full cylinder diameter. The yielding piston C permits the employment of a very small clearance-space between the said piston and the closed end of its cylinder. A second piston C⁵ is rigidly mounted in the upper 100 end of the receiver B, upon its integral stem C⁶. Under certain conditions it might be desirable to provide this piston with a yielding support similar to that of the piston C, but

for the sake of simplicity a rigid support for the upper piston is here employed.

When it is desirable to remove the receiver B, the piston C⁵ need not be disturbed, but 5 may be removed bodily with said receiver.

Two cylinders D and D', of equal diameter, are provided for the pistons C and C⁵, respectively. These cylinders are secured together end to end by the rivets D², their adjacent 16 ends being wholly closed and their outer ends open. An exhaust-port D³ is formed between the closed ends of the cylinders D and D', and said cylinders are provided with the peripheral radial steam-ports D⁴ and D⁵, respec-15 tively, which ports are for the admission of live steam to the cylinders and also for the escape of the exhaust therefrom. The cylinder D has a central tube D⁶, which tube, telescoping with the exhaust-tube B7, forms a 20 communication between said exhaust-tube B⁷ and the exhaust-port D³. D⁷ and D⁸ are closed air-spaces designed to prevent the loss of heat by conduction from the interior of the cylinders D and D', respectively, to the cooler ex-25 haust-port D³. Said spaces may readily be opened to the admission of live steam should such change be found desirable. By the foregoing arrangement of cylinders and pistons within a chamber filled with live steam it will 30 be seen that the temperature of the steam meeting surfaces is held at a point near to that of the live steam, and consequently that the initial condensation in the cylinders is almost wholly eliminated.

The cylinder D by the lugs D⁹, formed on diametrically opposite points of its periphery, provides means for the attachment of the cylinder-rods E, whereby the motion of the cylinders is transmitted to the crank-shaft A'. 40 These cylinder-rods E are of tubular form. They extend through packing-boxes E' in the base B' and have a rigid connection with the lugs D⁹. At their lower ends they are connected with the cross-head E2, which cross-45 head is free to move vertically upon the guides E³. A wrist-pin E⁴ connects the two parts of the cross-head E² and is surrounded by a sleeve E⁵, having the two oppositely-extending lugs

 E^6 . A two-part connecting-rod E^7 extends 50 downward from the lugs E⁶ to the usual con-

nection with the crank-pin A^2 .

Valve-rods F and F' extend through the tubular cylinder-rods E, forming a steam-tight joint therein. The lower ends of these rods 55 are connected by the pin F², which pin is surrounded by the sleeve F³, integral with the eccentric-rod F⁴, the lower end of which rod F⁴ movably embraces the eccentric F⁵, fixed upon the crank-pin A². The upper ends of 60 the valve-rods F and F' support a ring F⁶, which ring is provided with two opposite perforated ears F⁷. The rod F extends through one of said ears F⁷ and has a rigid connection therewith, while the rod F', extending 65 through the other one of said ears F7, has a

rotatable bearing in said ear. This last-mentioned valve-rod has a hand-lever F⁸ at its l

lower end, by means of which lever the said valve-rod F' may be oscillated within the tubular cylinder-rods E. This hand-lever F⁸ is 70 free to turn in its supporting-bracket, but is prevented from vertical movement. The lower end of the valve-rod F' is squared and is free to reciprocate vertically in the hub of the hand-lever F⁸, which hub is formed to re- 75 ceive the rectangular portion of said valverod. An arm F⁹ is rigidly secured to said valve-rod F' near the upper end of said rod. Said hand-lever F⁸ and the arm F⁹ are instrumental in providing a variable cut-off for the 80 steam-valve, which variable cut-off will be hereinafter described.

A valve-ring G surrounds the cylinders D and D' and is free to slide thereon. This ring has the usual steam-packing G' and is pro- 85 vided with an annular exhaust-channel G², communicating with said exhaust-port. The width of the valve-ring G is such with regard to the exhaust-port D³ and the distance between the steam-ports D⁴ and D⁵ that its reciproca- 90 tory movement opens one set of steam-ports for the admission of live steam and opens the other set of steam-ports to the exhaust-channel G² in the usual manner. It will be noticed that the eccentric for communicating 95 motion to the valve-ring G is mounted on the crank-pin A² instead of upon the crank-shaft, as ordinarily; but when it is remembered that the valve-ring G travels mainly with the cylinders D and D', having but a slight move- 100 ment relative thereto, the reason for such connection will be seen.

The circumferential groove G³ is provided in the lower part of the valve-ring G for the reception of the ring F^6 , upon which ring F^6 105 said valve-ring G has an oscillatory move-

ment.

By the connections hereinbefore described to wit, the eccentric on the crank-pin A^2 and the valve-rods—the valve-ring G is moved 110 longitudinally with the cylinders D and D' to admit live steam alternately into said cylinders through the ports D⁴ and D⁵, respectively. With reference to Fig. 1 it will be seen that the parts are there represented in 115 position for the steam to enter the ports D⁵ from the interior of the receiver B. Steam entering thus will drive the cylinder D downward, actuating the crank-shaft A' through the cylinder-rods E and the connecting-rods 120 E⁷. The eccentric connection with said crank-shaft will cause the valve-ring G to close the ports D⁵ at the proper moment and will also move the escape-channel G² into coincidence with said ports D⁵ when the cylin- 125 der reaches the lowest point of its stroke. This movement of the valve-ring G will also open the ports D4, permitting live steam to enter the cylinder D at the beginning of the upward stroke. The exhaust-steam escaping 130 through the ports D4 and D5 alternately finds its way from the channel G2 in the valve-ring G into the exhaust-port D³ and is discharged through the tubular central portion of the

640,238

cylinder D, the exhaust-tube B⁷, and the exhaust-port B⁶.

To provide for a variable cut-off, the valvering G is formed with the serrations G4, which 5 may be turned more or less into coincidence with the ports D⁴ and D⁵, so that said ports will be more or less quickly closed by the reciprocation of the valve-ring, accordingly as it is desirable to cut off the live steam earlier or later in the stroke.

To turn the valve-ring G, a pivotal link connection is made between the arm F⁹ near the upper end of the valve-rod F and a lug G⁵ on the valve-ring, whereby a slight oscil-15 latory movement of said valve-rod will correspondingly oscillate the valve-ring G upon its supporting-ring F⁶. The hand-lever F⁸ is provided for oscillating the valve-rod F, and thus changing the time of cut-off in the stroke; 20 but, while I have shown a hand-lever for this purpose, it is clear that in practice a connection may be made between the valve-ring G and some form of governor for automatically actuating said valve.

I have here particularly described my invention in its application to the vertical type of steam-engines; but it should be understood that the invention may readily be adapted to the horizontal type as well.

I claim as my invention—

1. In a steam-engine, in combination, a relatively-stationary piston, a reciprocatory cylinder for the piston, having steam-ports in said cylinder, and means for opening and clos-35 ing said steam-ports for the admission of live steam to said cylinder.

2. In a steam-engine, in combination, a steam-receiver, a piston mounted in said steam-receiver, a reciprocatory cylinder for 40 said piston, having steam-ports in said cylinder, and means for opening and closing

said steam-ports.

3. In a steam-engine, in combination, a steam-receiver, a piston mounted in said 45 steam-receiver, a reciprocatory cylinder for said piston, having steam-ports in said cylinder, means for opening and closing said steam-ports, a crank-shaft, and a connection between the cylinder and the crank-shaft.

4. In a steam-engine, in combination, a steam-receiver, a piston capable of a yielding motion mounted in said steam-receiver, a reciprocatory cylinder for said piston, having steam-ports in said cylinder, means for open-55 ing and closing said steam-ports, a crankshaft, and a connection between the cylinder and the crank-shaft.

5. In a steam-engine, in combination, a steam-receiver, two pistons in said receiver, 60 a reciprocatory cylinder for each of said pistons, having steam-ports in said cylinders, means for opening and closing said steamports, a crank-shaft, and a connection between the cylinders and the crank-shaft.

6. In a steam-engine, in combination, a steam-receiver, two pistons in said receiver, a reciprocatory cylinder for each of said pis-

tons, which said cylinders are secured together and have an exhaust-port between their adjacent walls, also having steam-ports 70 in each of said cylinders, means for opening and closing said steam-ports, a crank-shaft, and a connection between the cylinders and the crank-shaft.

7. In a steam-engine, in combination, a 75 steam-receiver, a piston rigidly secured within said receiver, a piston having a yielding support within said receiver, two cylinders for said pistons, rigidly secured together, having an exhaust-port between their adja- 80 cent ends and being provided with steamports in each of said cylinders, means for opening and closing said steam-ports, a crankshaft, and a connection between the cylinders and the crank-shaft.

8. In a steam-engine, in combination, a steam-receiver, a piston rigidly mounted within said receiver, a piston having a yielding support within said receiver, two cylinders closed at their adjacent ends and rigidly se- 90 cured together, having an exhaust-port between them, also having steam-ports for each of said cylinders, means for opening and closing said steam-ports, a crank-shaft, a connecting-rod, a wrist-pin, a cross-head, and a 95

cylinder-rod.

9. In a steam-engine, in combination, a steam-receiver, a piston rigidly mounted in one end of said receiver, an annular piston having a yielding connection with the opposite end 100 of said receiver, two cylinders closed at their adjacent ends and rigidly secured together, having an exhaust-port between them and being provided with peripheral steam-ports, means for opening and closing said steam- 105 ports, an exhaust-tube extending through the cylinder surrounding the annular piston, a crank-shaft, a connecting-rod, a cross-head, and cylinder-rods.

10. In a steam-engine, in combination, a 110 steam-receiver, a piston rigidly mounted within said receiver at one end thereof, an annular piston having a yielding connection with the opposite end of said receiver, a cylinder for the first-mentioned piston, a cylinder for the 115 last-mentioned piston, which latter cylinder has a central opening therein, an exhaust-tube telescoping within the said opening, means for securing said cylinders together at their closed ends, said cylinders being provided with an 120 exhaust-port between them and having a series of peripheral steam-ports for each cylinder, means for opening and closing said steamports, a crank-shaft, a connecting-rod, a crosshead, and a cylinder-rod.

11. In a steam-engine, in combination, a steam-receiver, a piston rigidly secured within said receiver to one end thereof, a cylinder closed at one of its ends for said piston and having a series of peripheral steam-ports in 130 its walls, an annular piston opposite the firstmentioned piston, having a yielding connection with said receiver, a cylinder for said annular piston having a central opening and

125

a series of peripheral steam-ports near its closed end, an exhaust-tube telescoping in the central opening in the last-mentioned cylinder, means for securing the two said cylinders together at their closed ends to allow an exhaust-port between them, means for opening and closing the steam-ports in said cylinders, a crank-shaft, a connecting-rod, a cross-head, and two cylinder-rods extending between the rocross-head and the last-mentioned cylinder.

12. In a steam-engine, in combination, two pistons, reciprocatory cylinders therefor, which cylinders are provided with peripheral steam-ports, a valve-ring surrounding said cylinders, and means for reciprocating said ring relative to said cylinders for opening and

closing said steam-ports.

13. In a steam-engine, in combination, two pistons, reciprocatory cylinders therefor, which cylinders are provided with peripheral steam-ports, a valve-ring surrounding said cylinders, which ring is serrated at its outer edges, means for reciprocating said ring relative to said cylinders for opening and closing said steam-ports, and means for turning said ring to place said serrations more or less in coincidence with the steam-ports.

14. In a steam-engine, in combination, two pistons, reciprocatory cylinders therefor, 30 which cylinders are provided with peripheral steam-ports, valve-rods, a supporting-ring mounted on said rods, a valve-ring having a bearing in said supporting-ring, which valve-ring is serrated at its upper and lower edges, an arm fixed on one of said valve-rods, a lug on the valve-ring, a link between said arm and said lug, and means for turning said

valve-rod.

15. In a steam-engine, in combination, a steam-receiver, two pistons in said receiver, a reciprocatory cylinder for each of said pistons, having steam-ports in said cylinders, a crank-shaft, a connection between the cylinders and the crank-shaft, two valve-rods hav-

ing a connection with the crank-shaft, a supporting-ring on the valve-rods, and a valvering surrounding the cylinders and mounted on said supporting-ring.

16. In a steam-engine, in combination, a steam-receiver, a steam-inlet pipe provided

at its side with an opening for admitting steam to said receiver, whereby the incoming steam is given a gyratory motion within said receiver, a piston mounted in said steam-receiver, a reciprocatory cylinder for said piston, having steam-ports in said cylinder, and means for opening and closing said steam-ports.

17. In a steam-engine, in combination, a steam-receiver, a piston rigidly mounted in 60 one end of said receiver, an annular piston for the opposite end of said receiver, which latter piston has an annular supporting-ring, coil-springs under said ring, bolts extending through openings in said ring and securing 65 said annular piston in position in said steam-receiver, two cylinders closed at their adjacent ends, and rigidly secured together, having an exhaust-port between them and being provided with peripheral steam-ports, means 70 for opening and closing said steam-ports, a crank-shaft, a connecting-rod, a cross-head, and cylinder-rods.

18. In a steam-engine, in combination, a steam-receiver, two pistons in said receiver, 75 a reciprocatory cylinder for each of said pistons, which cylinders are secured together and have an exhaust-port between their adjacent walls, also having steam-ports in each of said cylinders, means for opening and closing said steam-ports, a crank-shaft, a crosshead, cylinder-rods, and a bifurcated connecting-rod extending between the cross-head

and the crank-shaft.

19. In a steam-engine, in combination, a 85 steam-receiver, two pistons in said receiver, a reciprocatory cylinder for each of said pistons, which said cylinders are secured together and have an exhaust-port between their adjacent walls, also having non-conducting spaces between said exhaust-port and the cylinder ends, and being provided with steam-ports in each of said cylinders, means for opening and closing said steam-ports, a crank-shaft, and a connection between the 95 cylinders and the crank-shaft.
