United States Patent Office.

FRANK SNYDER, OF FULTON, NEW YORK, ASSIGNOR TO HUNTER ARMS COMPANY, OF FULTON, NEW YORK, A CORPORATION OF NEW YORK.

BREECH-LOADING FIREARM.

SPECIFICATION forming part of Letters Patent No. 694,331, dated February 25, 1902.

Application filed November 21, 1900. Serial No. 37,221. (No model.)

To all whom it may concern:

Be it known that I, FRANK SNYDER, of Fulton, in the county of Oswego, in the State of New York, have invented new and useful Improvements in Breech-Loading Firearms, of which the following, taken in connection with the accompanying drawings, is a full, clear, and exact description.

This invention relates to improvements in breech-loading firearms, and particularly to the ejector mechanism for extracting the car-

tridges.

The object of my invention is to produce a simple and practical mechanism removably supported on the barrels of the gun and adapted to operate an extractor-bar for forcibly ejecting the cartridges from the barrel when the gun is broken and only after the cartridge has been fired or discharged.

The further object of my invention is to provide means for starting the cartridge and moving the same a limited distance independently of the former mechanism when the gun is broken, whereupon a loaded cartridge may

25 be withdrawn by hand, if desired.

To this end the invention consists in the combination, construction, and arrangement of the component parts of an ejector mechanism, as hereinafter fully described, and

30 pointed out in the claims.

Figures 1, 2, 3, and 4 are similar elevations, partly in section, of my improved ejector mechanism, illustrating the successive operations of said mechanism for discharging the 35 cartridge and extracting the same from the barrel. Fig. 5 is a top plan view of the detached ejector mechanism as seen in Fig. 1. Fig. 6 is an end view of the gun-stock or frame, showing particularly the ends of the 40 cocking bars or levers. Fig. 7 is a rear end view of the detached fore-end piece and the ejector mechanism mounted thereon. Figs. 8 and 9 are isometric yiews, respectively, of one of the detached tumblers or kickers and 45 one of the sears for controlling the movement of the said tumbler or kicker.

Similar reference characters indicate cor-

responding parts in all the views.

As seen in the drawings, my improved ejector mechanism consists, essentially, of an extractor-bar 1, spring-actuated means 2 for out-

erating the extractor-bar, a sear 3 for controlling the operation of the spring-actuated means, and additional means 4 for starting the extractor-bar and moving the same a limited distance.

The extractor-bar 1 may be of any desired form, size, or construction, provided with a flanged head 5, separated stop-shoulders 6, and an abutting face 7. This extractor-bar is reciprocally movable in the barrel-frame, the head 5 being adapted to engage the rim of the cartridge for forcing said cartridge substantially parallel with the bore of the barrel. The stop-shoulders 6 are arranged to engage the opposite faces of a suitable stop 8, removably secured to the barrel-lug, and serves to limit the reciprocal movement of the extractor-bar. The spring-actuated means 2 for forcing the extractor-bar lengthwise of the barrel for forcibly ejecting the cartridge consists of a rock bar or lever pivoted at 9 and having one end adapted to engage the forward end face of the extractor-bar and its other end provided with an inclined face 10 and an engaging shoulder 11. The spring for actuating the rock-arm 2 is substantially V-shaped, consisting of two spring-arms 12 and 13, united at one end, the free end of the arm 12 being arranged to engage the end face 14 of the gunframe and is provided with an engaging shoulder 15 in proximity to its free extremity for engaging the sear presently described. The free end of the arm 13 is provided with an engaging shoulder 16 for engaging the inclined face 10 of the rock-arm or tumbler 2. being normally engaged with said tumbler at a point in proximity to its pivot 9, and is adapted to ride upon the inclined face 10 during the breaking of the gun for operating the tumbler 2 and forcing the extractor-bar outwardly a limited distance.

The united ends of the spring-arms 12 and 13 are movable in an inclined way 17, provided in a suitable block 18, which is secured to the fore-end piece of the gun in any desired manner. The inclined face 10 of the tumbler 2 usually inclines downwardly from its pivotal point 9, and it is evident that when the gun is broken the rear end of the spring-arm 12, abutting against the shoulder 14 of the gun-frame, thereby forces the spring for-

inclined way 17. The rear e downwardly-inclined face ressing the spring, it being he forward movement of said inclined way 17 also serves ompress the leaves of said ch other. The sear 3 is also fore-end piece, having one a suitable way or slot 19, lock 18, and its other end is engaging shoulder 20, nore path of the shoulder 11 of ig the movement of said tumrtridge has been discharged reaking of the gun.

s. 1 and 2, the shoulders 11 mally separated from each tance for permitting the tumed a limited distance before her for the purpose of movr-bar a slight distance, and the discharged cartridge

This sear 3 extends beyond id is provided at its rear end noulders 22 and 23, the shoulinged to engage the forward e cocking member a and the g disposed in the path of the espring-arm 12. When the e gun is forced to its cocked 1 in Fig. 1, by the cocking orward end of said cocking rlocked with the shoulder 22 ld the shoulder 20 of the sear h of movement of the shoulnbler 2.

15 and 23 are normally sepaother when the gun is closed, 1 and 2, and are arranged in each other that when the gun oulders 15 and 23 engage each he same time that the shoult of engagement with the forcocking-bar, and it is thereat the shoulder 15 serves to 3 forwardly and to hold the of the path of movement of the etumbler 2 when the shoulder out of engagement with the he cocking-bar. It is thus apn the hammer is in its cocked the cartridge has been fired he gun may be broken any es without ejecting the carbarrel. This feature of my ieved to be entirely new, and isly stated, the cartridge may racted during the breaking of dent that the cartridge canom the barrel by the ejector il the same has been fired or

ımmer has been released, as ind 3, the spring 21 forces the

20 into the path of movement of the shoulder during the breaking of the 11, and during the breaking of the gun said shoulder 11 engages the shoulder 20, thereby 70 limiting the movement of the tumbler 2 and permitting the spring-arms 12 and 13 to be tensioned toward each other by the inclined face 10 and the way 17. As the barrel continues its downward movement and the end 75 of the spring-arm 13 continues to ride upon the inclined face 10 of the tumbler 2 away from the pivot 9 the shoulder 15 of the springarm 12 engages the shoulder 23 of the sear, thereby moving the sear forwardly and forc- 80, a suitable spring 21 for the | ing the shoulder 20 out of engagement with the shoulder 11 of the tumbler 2, whereupon the spring-arm 13 instantly rocks the tumbler 2, and thereby forces the extractor-bar rearwardly for forcibly ejecting the cartridge 85 from the barrel.

As previously stated, the shoulders 15 and 23 are normally separated from each other and are only adapted to engage with each other when the barrel reaches the limit of its 90 downward movement, thereby compressing the spring as much as possible before the shoulder 20 is released from engagement with

the shoulder 11 of the tumbler 2.

By constructing and arranging the parts of 95 my ejecting mechanism as just described I am enabled to remove the loaded cartridge at any time desired, the extractor-bar is prevented from being actuated by the springs before the cartridge is fired, and the spring 100 is tensioned to its extreme limit and serves to eject the cartridge from the barrel with considerable force only at such time as the barrel reaches the limit of its downward movement.

105 The means 4 for moving the extractor-bar a limited distance independently of the mechanism just described consists of a plunger reciprocally movable in the frame of the gun, one end being adapted to engage the shoul- 110 der 7 of the extractor-bar and the other end being arranged to engage a suitable shoulder 25, formed on the forward end of the gunframe. By thus interposing the plunger 4 between the shoulder 7 of the movable barrel 115 and the fixed shoulder 25 of the gun-frame it is apparent that when the gun is broken the extractor-bar will be moved a limited distance for starting the cartridge from the barrel. This feature of my invention not only per- 120 mits a loaded cartridge to be withdrawn by hand, if desired, but also relieves the work of the spring-arm 13 and tumbler 2 after the. cartridge has been fired and the gun moved to the limit of its downward movement for 125 forcibly ejecting the cartridge.

Although I have shown and described an ejector mechanism for a single barrel, I have shown a double-barreled gun, each barrel being provided with one of the described mech- 13d anisms which operate independently of each other.

The cocking-lever previously referred to , thereby moving the shoulders may be of any desired form or construction,

and while I have shown a rock-shaft having ! its forward end provided with a laterally-extending arm having an engaging shoulder for engaging the shoulder 22 of the sear 3 and 5 its rear end provided with a cam for engaging the shoulder on the hammer and rocking the same to its cocked position, yet it is obvious that I may employ a reciprocally-movable bar operating for the same purpose as the rock-10 bar a herein shown and described.

The fore-end piece upon which the mechanism for operating the extractor-bar is mounted is provided with an inclined face 26, which engages the forward end of the cock-15 ing-bar for rocking the same when the gun is | broken, and thereby automatically cocking

the hammer in the usual manner.

The operation of my invention will now be readily understood upon reference to the fore-20 going description and the accompanying drawing, and it will be noted that considerable change may be made in the detail construction and arrangement of the parts of my invention without departing from the spirit 25 thereof. Therefore I do not limit myself to such precise construction and arrangement as herein shown and described.

Having thus described my invention, what I claim, and desire to secure by Letters Pat-

30 ent, is—

1. In a breech-loading firearm, an ejector mechanism comprising a spring-actuated extractor-bar, in combination with a hammer, and means controlled by the hammer for pre-35 venting the tensioning of the spring when the

hammer is cocked.

2. In a breech-loading firearm, an ejector mechanism comprising an extractor-bar, a spring-actuated tumbler for moving the ex-40 tractor-bar, means movable into and out of the path of movement of the tumbler for the purpose described, in combination with a hammer, and a cocking-bar for controlling the position of said means as the hammer as-45 sumes its cocked and firing positions.

3. In a breech-loading firearm, an ejector mechanism comprising an extractor-bar, a spring-actuated tumbler for moving the extractor-bar, a sear reciprocally movable into 50 and out of the path of the tumbler for the purpose described, in combination with a hammer, and a cocking-bar for controlling the position of the sear as the hammer is

cocked or fired.

4. In a breech-loading firearm, an ejector mechanism comprising an extractor-bar, a spring-actuated tumbler for moving the extractor-bar, a movable sear, a spring for foreing the sear into the path of the tumbler, in 60 combination with a hammer, and a cocking member adapted to hold the sear out of the path of the tumbler when the hammer is cocked.

5. In a breech-loading firearm, an ejector 65 mechanism comprising an extractor-bar, a spring-actuated tumbler for moving the extractor-bar, a spring-actuated sear for hold- tumbler for the purpose describe

ing the tumbler in its inoperat and means for forcing the sear to tive position when the gun is dis broken.

6. In a breech-loading firearm nation with the frame and barre tor mechanism mounted on th comprising an extractor-bar, a ated tumbler for actuating the b controlling the movement of the means mounted on the frame and the hammer for controlling the p sear.

7. In a breech-loading firearn nation with the frame and barre tor mechanism mounted on the comprising an extractor-bar, a ated tumbler for actuating the b controlling the movement of the means engaged with the frame fo sear to its inoperative position v

is broken.

8. In a breech-loading firearm nation with the frame and barre tor mechanism mounted on the comprising an extractor-bar, a ated tumbler for actuating the b controlling the movement of the cocking-bar mounted on the fra ing the sear in its inoperative po the hammer is cocked and for r same when the hammer is fired,: for forcing the sear to its operat

9. In a breech-loading firearm nation with the frame and barrel tor mechanism mounted on the comprising an extractor-bar, a actuating the bar and provided face, a support, and spring-arms responding ends movably mounte port and their opposite ends enga tively with the frame and with sa

10. In a breech-loading firearm nation with the frame and barrel tor mechanism mounted on the comprising an extractor-bar, a actuating the bar and provided face, a support, and spring-arms responding ends movably mounte port and their opposite ends eng tively with the frame and with sai a spring-actuated sear movable i of the tumbler, said sear being for the path of the tumbler by the spring engaging with the frame a broken for the purpose described

11. In a breech-loading firearm nation with the frame and barrel; tor mechanism mounted on the comprising an extractor-bar, a actuating the bar and provided face, a support having an inclin face, and spring-arms having co ends mounted on the inclined l and their opposite ends engaged 1 with the frame and with the cam

me and barrel; of an ejecounted on the barrel and ractor-bar, a pivoted tumthe bar and provided with nding outwardly from its laving a guideway and an ace, a sear guided in the the purpose described, a the sear into the bath of g-arms having correspondd movable on said bearingosite ends engaged respecf the spring arms being arsear out of the path of the gun is broken.

loading firearm, the combi-ime and barrel; of an ejecounted on the barrel and ractor-bar, a pivoted tum- H. E. CHASE, the bar and provided with

loading firearm, the combi- a cam - face extending outwardly from its pivot, a support having a guideway and an 25 inclined bearing-face, a sear guided in the ways and movable into and out of the path of the tumbler for the purpose described, a spring for forcing the sear into the path of the tumbler, spring-arms having correspond- 30 ing ends united and movable on said bearinge into and out of the path | face and their opposite ends engaged respectively with the frame and the cam-face of the tumbler, one of the spring-arms being ar-*ranged to force the sear out of the path of the 35 tumbler when the gun is broken, and a cocking-bar mounted on the frame and adapted ame and the cam-face of to hold the sear out of engagement with the tumbler when the hammer is cocked.

In witness whereof I have hereunto set my. 40

hand this 20th day of October, 1900.

FRANK SNYDER.

Witnesses:

HOWARD P. DENISON.
