W. R. MACKLIND. RAILROAD CROSSING.

(Application filed Aug. 10, 1901.)

(No Model.)

UNITED STATES PATENT OFFICE.

WILLIAM R. MACKLIND, OF ST. LOUIS, MISSOURI.

RAILROAD-CROSSING.

SPECIFICATION forming part of Letters Patent No. 696,376, dated March 25, 1902.

Application filed August 10, 1901. Serial No. 71,566. (No model.)

To all whom it may concern:

Be it known that I, WILLIAM R. MACKLIND, a citizen of the United States, residing at St. Louis, Missouri, have invented a certain new and useful Improvement in Railroad-Crossings, of which the following is a full, clear, and exact description, such as will enable others skilled in the art to which it appertains to make and use the same, reference being had to the accompanying drawings, forming part of this specification, in which—

Figure 1 is a top plan view, one of the wearing-surface sections being removed. Fig. 2 is an elevation, chiefly in section, on the line 22 of Fig. 1, both wearing-surface sections being illustrated in position. Fig. 3 is an end elevation; and Fig. 4 is a sectional elevation on the line 4 4 of Fig. 1, the wearing-surface

section being shown in position.

My invention relates to improvements in railroad-crossings, my objects being to provide a crossing so constructed that all jolting and jarring of the car are avoided, that there is presented a renewable wearing-surface securely held to the base, and that the members forming the crossing are securely held in position.

To these ends and also to improve generally upon constructions of the nature indicated my invention consists in the various matters

hereinafter described and claimed.

Referring now more particularly to the drawings, A A represent the base crossing-sections, and BB the renewable wearing-surface 35 sections, there being provided two of each of said sections and the members of each respective sections being interchangeable. Each base-section comprises a main rail-section a, extending between the lines of the usual track-40 rails and having longitudinal extensions a' at its ends, adapted to register with the usual track-rails, there being also provided angular extensions a^2 and a^3 , the former projecting away from and the latter projecting toward 45 the central line of the crossing and said extensions a^3 being one-half the length of the space between the crossing rails. The heads a^4 of the base-sections are provided in their upper surfaces with grooves a^5 , in which the 50 wearing-surfaces B are secured. Each wearing-surface section B has sections b, b', b^2 , and b^3 , corresponding with the respective sec-

tions of the base-sections. The crossing is therefore composed of four sections, which are generally similar in plan, the two base-sec- 55 tions combining to form the complete base and the two wearing-surface sections combining to complete the corresponding wearing-surface for said base. I prefer, however, to so assemble the before-mentioned parts that the 60 joints between the base-sections shall be upon the sides of the crossing other than those upon which the wearing-surface joints occur. Thus the joints between the base-sections occurring at diametrically opposite points upon 65 one track the wearing-surface sections will be so placed that their joints occur at diametrically opposite points of the transverse track, and the said wearing-surface sections being secured in the grooves formed in the base- 70 sections the entire crossing is thus by its own parts securely locked together and held against spreading or twisting.

Manifestly the wearing-surfaces can be fastened upon the base in many ways; but I pre- 75 fer for this purpose to employ headed bolts b^4 , extending from top to bottom through the assembled wearing-surface and projecting base-head, nuts b^5 being applied to the portions of said bolts below the said base-head. 80 This construction results in firmly clamping the wearing-plates in position in such manner that the passage of cars does not tend to jar the bolt loose, an evil which must follow in those constructions in which the bolt ex- 85 tends horizontally through the webs of the base and wearing-plate and must, therefore, initially have some slight play in the boltholes. Furthermore, as will be more fully hereinafter explained, the bolt-heads b^4 are go placed in the portions of the wearing-surface which are not engaged by the car-wheels, and said heads are thus saved from wear.

Each wearing-surface has at its outer portion—i. e., its portion farthest removed from 95 the center of the crossing—a tread 1, which corresponds generally with the tread of the track, while just inside of said tread is a groove 2, corresponding with the usual trackgroove. A guard-rail 3 is formed upon the 100 wearing-surface at the inner side of the groove for a well-known purpose. At the outer points of the crossing—i. e., the points adjacent the usual track ends—the treads 1 are

of the height of the treads of the track-rail; but at a point considerably removed—say about two feet—from the intersection of the crossing rails each tread 1 commences to in-5 cline gradually downward and toward the central line of the crossing. At a point in advance of the before-mentioned intersection the tread has decreased in height to merely the height of the wheel-flange; but said tread conto tinues to decrease in height until it is of less height than said wheel-flange and only sufficiently high to preserve the groove 2, the upper face of the wearing-surface being substantially horizontal, but of less height than 15 that of the wheel-flange, entirely across the space between the crossing rails. The crossing is thus grooved for its entire width; but between the crossing rails and for a distance at each side of a given set of said rails the tread 20 is of less height than is the wheel-flange, whereby at a suitable point before reaching the intersecting tracks the wheel-flanges, which have previously been held out of contact with the bottoms of the track-grooves by 25 reason of the wheel-treads bearing upon the track-treads, are gradually lowered until they ride upon the bottoms of said grooves 2, the wheel-treads then moving entirely across the crossing above and out of contact with the 30 treads of the wearing-surfaces, (which combine with the base-sections A to form, in effect, rails,) and when the wheels have reached the opposite side of the crossing the wheeltreads gradually ride upon the upwardly-in-35 clining treads of the wearing-surfaces, and thus carry the wheel-flanges into normal position above and out of contact with the bottoms of the grooves 2. Furthermore, during the passage of a wheel across the crossing it is 40 guided by the groove 2, so that all jarring or jolting heretofore due to sudden vertical inequalities in the tracks at the rail intersections or to lateral displacement of the wheels at such intersections are rendered impossible. 45 The before-mentioned bolt-heads b^4 are placed in the portion of the wearing-surface tread which is not engaged by the wheel-tread—i. e., in the before-described lower wearing-surface tread portion—whereby said bolt-heads are

I am aware that many minor changes in the construction, arrangement, and combination of the several parts of my invention can be made and substituted for those herein shown 55 and described without in the least departing from the nature and principle of the invention.

50 saved from wear.

Having thus described my invention, what I claim as new, and desire to secure by Letters. 60 Patent of the United States, is—

1. In a railroad-crossing or the like, basesections, each having a main rail-section and an angular section extending toward the central line of the crossing, and a wearing-sur-65 face section having a main section extending across the said angular sections of said basesections and angular sections in line with the

said main rail-sections of said base-sections, there being locking engagement between said main rail-sections of the base and said angu- 70 lar sections of said wearing-surface, whereby said wearing-surface section serves to lock said base-sections against displacement; substantially as described.

2. In a railroad-crossing or the like, wear- 75 ing-surface sections each having a main section and an angular section extending toward the central line of the crossing, and a basesection having a main rail-section extending across the said angular sections of said wear- 80 ing-surface sections and angular sections in line with the said main sections of said wearing-surface sections, there being locking engagement between said main sections of said wearing-surface and said angular sections of 85 said base, whereby said base-section-serves to lock said wearing-surface sections against displacement; substantially as described.

3. In a railroad-crossing or the like, complementary base-sections each having a main 90 rail-section and angular sections extending toward the central line of the crossing, the joints between said base-sections being upon opposite sides of the crossing, and complementary wearing surface sections fitting upon 95 said base, each wearing-surface section having a main section and angular sections extending toward the central line of the crossing, the joints between said wearing-surface sections being upon sides of the crossing other 100 than those upon which occur the joints between said base-sections, there being locking engagement between the said wearing-surface sections and base-sections upon all four sides of the crossing, whereby said several 105 sections serve to lock each other against displacement; substantially as described.

4. In a railroad-crossing or the like, basesections each having a main rail-section and an angular section extending toward the cen-110 tral line of the crossing, and a wearing-surface section having a main section extending across the said angular sections of said basesections and angular sections in line with the said main rail-sections of said base-sections, 115 there being groove connection between said main rail-sections of the base and said angular sections of said wearing-surface, and means for securing said main section of the wearingsurface against lateral displacement upon said 120 angular sections of said base; substantially as described.

5. In a railroad-crossing or the like, complementary base-sections each having a main rail-section and angular sections extending 125 toward the central line of the crossing, the joints between said base-sections being upon opposite sides of the crossing, and complementary wearing-surface sections fitting upon and having groove connection with said base, 130 each wearing-surface section having a main section and angular sections extending toward the central line of the crossing, the joints between said wearing-surface sections being

upon sides of the crossing other than those upon which occur the joints between said base-sections; substantially as described.

6. The combination with a rail-base, of a 5 separate wearing-surface upon said base, and a bolt extending from top to bottom through suitable portions of said base and wearingsurface and securing said parts together, the head of said bolt lying in the tread of said 10 wearing-surface and in a portion thereof not engaged by the wheels; substantially as described.

7. In a railroad-crossing or the like, a wearing-surface having a tread portion and a 15 wheel-guard, a groove for the wheel-flange being formed between said tread and wheelguard, said tread extending entirely across the crossing but between points outside of the rail intersections being reduced to a height 20 less than that of the wheel-flange and said lower tread portion being connected to the normal tread portions by gradual inclines; substantially as described.

8. In a railroad-crossing or the like, a base, a separate wearing-surface upon said base, 25 said wearing-surface having grooves extending across the rail intersections, the wearingsurface tread between points outside of said intersections being of less height than the flange of the wheel designed to run upon said 30 tracks and said lower tread portions being connected to the normal tread portions by gradual inclines, and bolts connecting said base and wearing-surface and extending from top to bottom through the same, the bolt- 35 heads lying in the before - mentioned lower tread portion, whereby they are not engaged. by passing wheels; substantially as described.

In testimony whereof I hereunto affix my signature, in the presence of two witnesses, 40

this 8th day of August, 1901.

WILLIAM R. MACKLIND.
