J. J. GERARD.

FEED MECHANISM FOR ROLLER MILLS.

APPLICATION FILED NOV. 2, 1903.

UNITED STATES PATENT OFFICE.

JOHN J. GERARD, OF MINNEAPOLIS, MINNESOTA, ASSIGNOR TO ALLIS-CHALMERS COMPANY, OF CHICAGO, ILLINOIS, A CORPORATION OF NEW JERSEY.

FEED MECHANISM FOR ROLLER-MILLS.

SPECIFICATION forming part of Letters Patent No. 775,350, dated November 22, 1904.

Application filed November 2, 1903. Serial No. 179,542. (No model.)

To all whom it may concern:

Be it known that I, John J. Gerard, a citizen of the United States, residing at Minneapolis, in the county of Hennepin and State 5 of Minnesota, have invented a new and useful Feed Mechanism for Roller-Mills, of which

the following is a specification.

My invention relates to feed mechanism for roller-mills; and its object is to provide a con-10 struction in which the feed may be more accurately and rapidly adjusted, the wear diminished, a greater exposed feed-surface provided, and the possibility of the dropping through of the material between the feed-roll 15 and the hopper-board more efficiently avoided than in the existing constructions. I also provide a double adjustment, automatic and positive, for the depth of feed.

Other objects of the invention will appear 20 from the following specification and the ac-

companying drawings, in which—

Figure 1 is a sectional view on the line x x, Fig. 2, of the various parts of the feed. Fig. 2 is a sectional view on the line y y, Fig. 1. 25 Fig. 3 is a detailed sectional view of the feedgate adjustment.

Referring to Fig. 1, the material in the hopper 1 is fed to the rollers (shown diagrammatically) by the roll rotating in the direction 30 of the arrow shown. The amount of feed is regulated by the adjustment of the feed-gate 3. The feed-roll 2 rotates in close proximity to the back hopper-board 4. In order to prevent the material from dropping through be-35 tween said hopper-board and the feed-roll, a shield of sheet metal 5 is attached to the lower edge of the board and surrounds a part of the circumference of the roller, extending the full length of the roller. The edge of said 40 shield is in line with the edges of the side hopper-boards, as shown, in order to form a tight joint everywhere. In previous constructions the joint between the back hopper-board and the roller has been formed by arranging said 45 board radially or nearly radially to the feedroll and touching the latter. As this feedroll is corrugated, it will be understood that the wear is very rapid, and a space will soon

form through which the material can drop on the rollers. By my construction the hop- 50 per-board is arranged tangentially to the feedroll and in conjunction with the shield forms a perfectly tight joint, not depending upon close proximity of the roll and board. Besides this, because of the tangential arrange- 55 ment of the hopper-board, there is a greater exposed feed-surface, giving less liability of stoppage of feed. The feed-gate 3 is made adjustable with relation to the feed-roll in two directions—laterally and vertically. The 60 vertical adjustment consists of the adjusting-screws 6, provided with thumb-nuts, attached thereto, as shown. These adjustingscrews fit in corresponding sockets in the feedgate. In order to allow the swinging of the 65 gate away from the feed-roll, a semispherical block 7 is placed under the head of the adjusting-screw and rests on the edges of an opening in the plate 8. This plate 8 is provided with longitudinal slots 9 9, through which 7° pass screws 10, which attach the plate to the hopper-cover. By means of these longitudinal slots the plate, and consequently the feedgate, can be adjusted laterally. It will thus be seen that the position of the feed-gate with 75 relation to the feed-roll may be adjusted to any point between the extreme outer and the highest point of the circumference of said feed-roll. In other words, the feed-gate may be adjusted from a tangential to a radial po- 80 sition, thus giving the widest possible range of adjustment of feed-surface. The space between the edge of the feed-gate and the roll may be automatically regulated by means of the arms 11, mounted on rock-shafts 12, 85 passing through the casing and carrying rockarms 13, provided with adjustable weights in the well-known manner. In order to positively determine this space, thumb-screws 14 are provided, so located that the feed-gate 90 will abut against them. By adjusting these thumb-screws the space can be positively limited. The depth of the feed can thus be either automatically or positively regulated at will.

The construction described is duplicated on 95

both sides of the mill, as shown.

Having thus described my invention, what I claim is—

1. In feeding mechanism for roller-mills, in combination with the feed-gate, a vertical ad-5 justment and suspension therefor, consisting of plates provided with perforations, rounded blocks resting on the edges of the perforations, and adjusting-screws passing through

the blocks and supported thereby.

2. In feeding mechanism for roller-mills, in combination with the feed-gate, a combined vertical and lateral adjustment and suspension therefor, consisting of plates provided with perforations and slots and adjustable 15 laterally on fastening means passing through the slots, rounded blocks resting on the edges of the perforations, and adjusting-screws connected to the feed-gate, passing through the

blocks and supported thereby.

3. In feeding mechanism for roller-mills, a 20 feed-gate, a vertical adjustment for said feedgate consisting of adjusting-screws, a plate pivotally supporting said adjusting-screws and gate, and means for laterally adjusting said parts.

In testimony whereof I have signed my name to this specification in the presence of two subscribing witnesses.

JOHN J. GERARD.

Witnesses:

J. F. HARRISON, Mamie R. Bacon.
