W. H. H. TRACY.

CREASING MACHINE.

APPLICATION FILED MAY 22, 1905.

## UNITED STATES PATENT OFFICE.

WILLIAM H. H. TRACY, OF TROY, NEW YORK.

## CREASING-MACHINE.

No. 815,234.

Specification of Letters Patent,

Patented March 13, 1906.

Application filed May 22, 1905. Serial No. 261,519.

To all whom it may concern:

Be it known that I, WILLIAM H. H. TRACY, a citizen of the United States, and a resident of Troy, Rensselaer county, State of New York, have invented certain new and useful Improvements in Creasing-Machines, of which the following is a specification.

My invention relates to machines for creasing collars and cuffs, and has for its object to provide a simple and efficient device of this

character.

My invention will be described in detail hereinafter, and the features of novelty will be pointed out in the appended claims.

Reference is to be had to the accompany-

ing drawings, in which-

Figure 1 is a plan view of a machine constructed according to my invention. Fig. 2 is a sectional view thereof on the line 2 2 of Fig. 1. Fig. 3 is a sectional view taken on line 3 3 of Fig. 2. Fig. 4 is a detail view of another form of creasing-rollers, and Fig. 5 is a detail view of still another form of creasing-rollers.

A represents the base of the machine, provided with standards B and B'. Attached to these standards B and B' is a protecting-hood C, secured in position by screws C'.

A driving-shaft D is journaled in bearings
3° E and E' in the standards B and B' and has
mounted upon it at the end a driving-pulley
D', to which power may be applied in any
suitable manner. At its other end the said
shaft D carries a creasing-roller D<sup>2</sup>. A counter-shaft F, journaled in bearings F' and F<sup>2</sup> in
the standards B and B', also carries a creasing-roller G at its one end and has mounted
upon it a gear-wheel H, which meshes with a

corresponding gear-wheel I on the shaft D.
Thus as power is applied to the pulley D' the driving-shaft D is rotated and through the medium of the gears H and I transmits power to the counter-shaft F, thus rotating the crossing rollers D' and C

the creasing-rollers D<sup>2</sup> and G.

J is a table adapted to receive the material. A guide J' is secured to this table J by means of a screw J<sup>2</sup>. This guide may be of any suitable and well-known form to guide the folded material to the creasing-rollers D<sup>2</sup> and G.

Mounted on the counter-shaft F to rotate therewith is a cam K, which coöperates with a rocker-arm L. This said rocker-arm is provided with a roller L' at the point where it engages the cam Kin order to reduce the friction. The rocker-arm L is pivoted at L2 to a

55 tion. The rocker-arm L is pivoted at L<sup>2</sup> to a lug or projection A' on the base A and is pro-

vided at its one end with a stud L³, which engages the bearing F² for the purposes to be

more fully described hereinafter.

To accommodate goods or material of va- 60 rying degrees of thickness, there is provided a spring M, mounted in a casing M' and with its one end in engagement with a washer M², abutting against the bearing E'. The other end of the spring M is in engagement with an 65 adjustable cap M³, which screws into the upper end of the casing M'. A rod N, provided with an enlargement or collar N', passes through this cap M³ and has its lower end screw - threaded and screws through the 70 washer M² and into the bearing E'. The object of this construction will appear from the description hereinafter.

The operation of the device is as follows: After the several thicknesses of material have 75 been sewed together to form the collar in the usual manner the said material is folded or bent over at one end and inserted into the guide J' and between the rollers D<sup>2</sup> and G. Power now being applied to revolve the roll- 80 ers D<sup>2</sup> and G, the material will be fed along and creased as it travels. As the shaft F is revolved the cam K will cause the rocker-arm L to vibrate and the roller G to alternately move toward and away from the roller D2. The object of this intermittent motion is to allow the material being creased to be gradually turned to accommodate the curved or irregular line, upon which the edge of the collar may be cut. If the rollers were con- 90 stantly in engagement, it would be impossible to turn the material without buckling it. In order to prevent the roller D<sup>2</sup> from following the roller G when said roller G drops away as the rocker-arm L is operated by the 95 cam K, the rod N is provided, the enlargement or collar N' of which engages the cap M3, and thus limits the downward movement of the bearing E' and the roller G. It will be understood that the bearing F', in which the 1co counter-shaft F is journaled, is so arranged as to permit of the limited downward swinging movement of the shaft F and the roller G when the end of the arm L passes into the cutout portions of the cam K and, further, that 105 the said shaft F and the roller G drop down by gravity.

In the form of creasing-rollers shown in Fig. 4 the upper roller d may be of the same character at the roller  $D^2$  described above, 110 while the lower roller g is a mutilated roller—that is, said roller is in feeding or creasing en-

gagement with the roller d intermittently, thus permitting the goods to be turned, as

mentioned hereinbefore.

In the structure shown in Fig. 5 both the rollers 1 and 2 are of the mutilated type, engaged intermittently in the same manner and for the same reasons as described with rela-

tion to Fig. 4.

It will be understood that when the creasing-rollers shown in either Fig. 4 or Fig. 5 are used the cam K and the rocker-arm L will be omitted and the bearing F<sup>2</sup> will be made stationary. Otherwise the remaining mechanism may be the same as described with respect to Figs. 1, 2, and 3.

I wish it understood that while I have described my invention in connection with collars and cuffs the said machine may be used whenever it is desired to crease material for

20 any purpose.

Various modifications may be made without departing from the nature of my inven-

tion.

The intermissions occurring in the feeding movement release the fabric sufficiently to enable it to be turned so that the crease will be curved to correspond to the edge of the article. The guide J' simply folds the material preparatory to creasing it and governs the distance of the crease from the edge.

It is unnecessary when using my invention to indicate the crease by a line on the goods or to use any particular care in order to have the crease at a uniform distance from the

35 edge.

I claim as my invention—

1. In a creasing-machine, the combination

of two rollers geared together so as to rotate continuously in opposite directions one of said rollers being movable toward and from 40 the other without bringing them out of gear, and means for shifting the movable roller toward and from the other roller at regular intervals as the rollers rotate.

2. In a creasing-machine, the combination 45 of two creasing-rollers permanently geared together, and means for alternately separating the working surfaces of the rollers and again bringing them into coöperative relation at regular intervals during the revolution of 50

the rollers.

3. In a creasing-machine, the combination of two creasing-rollers, one of which is movable toward and from the other, means for rotating said rollers in opposite directions, 55 and a shifting device, governed by said means, for shifting said movable roller toward and from the other roller.

4. In a creasing-machine, the combination of two creasing-rollers, one of which is mov- 60 able toward and from the other, means for rotating said rollers in opposite directions, a rocker-arm extending lengthwise of the shaft of the movable roller and connected therewith to shift said roller, and means, located 65 on one of the roller-shafts, for periodically swinging said rocker-arm.

In testimony whereof I have hereunto set my hand in the presence of two subscribing

witnesses.

WILLIAM H. H. TRACY.

Witnesses:

J. E. Hoag, P. J. McGowan.
