UNITED STATES PATENT OFFICE.

GEORGE THORN REED, OF BALTIMORE, MARYLAND, ASSIGNOR TO CONTINENTAL JAR & BOTTLE STOPPER COMPANY, OF BALTI-MORE, MARYLAND, A CORPORATION.

FIBER CLOSURE FOR JARS AND JELLY-GLASSES.

No. 827,667.

Specification of Letters Patent.

Latented July 31, 1906.

Application filed July 3, 1905. Serial No. 268,082.

To all whom it may concern:

Be it known that I, George Thorn Reed, a citizen of the United States, residing at Baltimore, in the State of Maryland, have 5 invented certain new and useful Improvements in Fiber Closures for Jars and Jelly-Glasses; and I do hereby declare the following to be a full, clear, and exact description of the invention, such as will enable others skilled in the art to which it appertains to

make and use the same.

My invention is directed to means for preventing the deterioration of preserves and analogous substances put up in jars, jelly-15 glasses, and the like; and for this purpose I have produced a closure of cap form made of wood-pulp and paraffin and having a construction of outer and inner annular walls or flanges adapted to have an elastic, sticking, 20 and adhesive sealing function upon the outer and upon the inner walls and the edge of a jar to effect an air-tight sealing, such elastic and adhesive walls being integral with the crown or disk of the closure and forming a 25 self-binder fastening in which each wall or flange in applying the cover will yield to any irregularity in the glass, while the element of paraffin which gives to the closure under heat a sticking character will cause its walls to 30 stick to the glass, rendering it thereby airtight.

The closure is non-corrosive and is not affected by acids and its preparation renders

it antiseptic and free from germs.

The accompanying drawings illustrate my improved fibrous cap-closure, which has both an elastic and an adhesive function in its sealing capacity as an envelop cover on the outer and inner walls of the jar.

Referring to the drawings, Figure 1 shows a jar having my improved closure-cap in vertical section, the cap being in partial perspective. Fig. 2 is a like view of a differentshaped cap. Fig. 3 shows my improved cap 45 as applied to a jelly-glass. Fig. 4 shows the

cap in perspective.

The cover is of cap form, preferably of woodpulp and paraffin in suitable proportions and pressed by dies into disk form with an annu-50 lar circumferential flange or wall 1, an inner circumferential flange or wall 2, and an annular top ridge 3, connecting the walls or

flanges and forming an interior groove 4, surrounding the crown or disk 5, so that the latter joins the inner edge of the groove. The 55 walls or flanges forming the grooves may have sharp or rounded angles or corners and the sealing walls or flanges may be of equal or of unequal width and each has a plain surface, so as to have a saddle fitting over and 60 upon the edge and upon the walls of the jar, each closure-wall fitting, by reason of its composite elastic material, with a binding function at every part of the annular walls upon the outer and upon the inner walls of the jar. 65

The wood fiber gives a certain elasticity to every part of the closure, while the paraffin gives a homogeneous and tough quality to the wood fiber and also an adhesive or sticking quality, and so far as I know and can find 70 I am the first to produce a fibrous enveloping closure for a jar having exterior and interior joint-forming walls or flanges, each wall having an elastic and an adhesive sealing function upon the inner and upon the outer walls 75 of the jar. In applying the cap-closure there is no danger of breaking the glass, and the element which gives the adhesive or sticking function of the sealing-walls of the cap is rendered active and effective by subjecting the 80 closure to a low degree of heat before applying the cap, or the heat of the jar imparted to it from its contents will be sufficient to develop the adhesive quality of the paraffin when the closure is firmly applied, or this 85 sticking function of the closure may be rendered effective by applying the closure-cap to the jar in a damp condition, so that in drying the walls or flanges of the closure will shrink tight and close all the crevices in the 90 walls of the jar, making the closure self-sealing and self-fastening.

In bleaching of the pulp to render it white all germs are killed, and the cap when formed is elastic at every part and can be stretched 95 in pressing it on the jar, and this with the adhesive and the shrinking functions will maintain an air-tight and a fastened closure.

The closure is preferably of uniform thickness, and the crown or disk is preferably con- 100 vex to have a yielding bracing function upon the inner wall or flange, tending to press said flange against the inner wall of the jar. In packing the jars for transportation the

annular crown of the groove will act as a cushion to the superposed jar to prevent breakage.

In Fig. 2 the closure walls or flanges are about equal width. In Figs. 1 and 3 the outer wall or flange is of greater width than the inner wall, and in either case the walls of the jar are unbroken by shoulder or groove, so that the closure is easily applied and removed and may be ornamented and made of various colors. I prefer to make the closure-cap from wood-pulp; but obviously equivalent material may be used which will have an elastic sealing function upon the jar-walls, while paraffin or its equivalent will impart to the walls an adhesive quality

the walls an adhesive quality. The importance of bulging or convexing the crown of the cap or closure resides in its capacity to yield to be fitted upon jars the 20 diameters of which may be of uneven circle or slightly larger than the outer graspingwalls of the cap; but this advantage is only possible in a cap of the yielding character described. Another advantage of this cap is 25 the spring function of its double graspingwalls allows them to be fitted and sprung upon walls of slightly greater thickness than the space between the grasping-walls and to conform to any unevenness or irregularity in 30 the circle of the jar-walls. This expansivespring function is rendered active in applying pressure upon the convex crown, and the pressure being removed the grasping-walls will, in contracting, having a binding force, 35 and this function will render the closure-cap effective as a bottle-stopper when applied

I claim—

under heat.

1. A fiber closure for vessels having as a component an adhesive element and comprising a central disk, an inner annular wall or flange integral with said disk, an outer annular wall integral with the inner wall, and an annular ridge connecting and forming a groove between said walls, the walls of the groove being adhesive in their closure function.

2. A fiber closure for jars having as a component an adhesive element and having a central

disk, an outer and an inner annular wall or 50 flange, said walls being elastic and adapted for elastic, adhesive and sealing engagement with the inner and the outer walls of a jar.

3. As an improved article of manufacture a closure for jars, consisting of wood fiber and 55 paraffin formed with a disk having inner and outer annular walls or flanges, each wall be-

ing both elastic and adhesive.

4. A fiber closure for jars having as a component an adhesive element and having an 60 outer circumferential wall or flange, an inner concentric wall or flange, both walls rendered adhesive, and a bulging or convex crown joining the edge of the inner wall whereby to cause an expansion in the diameter of the 65 grasping-walls in applying the cap and the sealing of the jar-walls.

5. A cap - closure for vessels formed of wood-pulp and paraffin having circular double walls, or flanges, each adapted to be rendered 70 adhesive under heat to adapt them to stick

to and seal the walls of the vessel.

6. A fiber cap for jars and the like having an adhesive substance and formed with a plurality of annular circumferential walls or 75 flanges caused to have a binding function to render it self-sealing and self-fastening when applied under heat.

7. As a new article of manufacture a closure for vessels consisting of a thin flexible 80 cap of fiber including an adhesive element and adapted to fit and inclose the inner and the outer walls of the vessel and having a

sealing and sticking function.

8. A removable flexible cap for vessels 85 formed of fiber pulp including an adhesive element and with an inner and an outer wall or flange adapted to inclose and to seal the inner and the outer walls of the neck of the vessel with a flexible sticking function.

In testimony whereof I have signed my name to this specification in the presence of

two subscribing witnesses.

GEORGE THORN REED.
