UNITED STATES PATENT OFFICE.

WILLIAM EDWARD LYFORD, OF THOMPSONVILLE, CONNECTICUT, ASSIGNOR TO THE HARTFORD CARPET CORPORATION, OF THOMPSONVILLE, CONNECTICUT, A CORPORATION OF NECTICUT.

YARN-PRINTING MACHINE.

No. 840,353.

Specification of Letters Patent.

Patented Jan. 1, 1907.

Application filed June 28, 1906. Serial No. 323,804.

To all whom it may concern:

Be it known that I, WILLIAM EDWARD LY-FORD, a citizen of the United States, and a resident of Thompsonville, in the county of 5 Hartford and State of Connecticut, have invented new and useful Improvements in Yarn-Printing Machines, of which the following is a full, clear, and exact description.

The invention relates to yarn-printing ma-10 chines for producing printed yarns, such as are used by carpet-manufacturers in making tapestry and other carpets, rugs, and like fab-

· rics.

The object of the invention is to provide 15 certain new and useful improvements in yarn-printing machines whereby a proper and intense rubbing or scraping of the color is had to insure a thorough penetration of the color into the yarn, thus producing a 20 printed yarn of high quality.

The invention consists of novel features and parts and combinations of the same, which will be more fully described hereinafter and then pointed out in the claims.

A practical embodiment of the invention is represented in the accompanying drawings, forming a part of this specification, in which similar characters of reference indicate

corresponding parts in all the views.

Figure 1 is a side elevation of a yarn-printing machine provided with the improvement. Fig. 2 is a plan view of the same, the printing-drum being shown in dotted lines. Fig. 3 is a front end elevation of the same. 35 4 is an enlarged end elevation of the traversecarriage, parts being shown in section. Fig. 5 is a sectional front view of part of the mechanism for moving the rubbing devices out of action whenever desired, and Fig. 6 is 4° a perspective view of one of the rubbing or scraping blocks.

The printing-drum A, of any approved construction, is journaled on the frame B, supporting the track C for the traverse-carriage 45 D to travel on in the usual manner. The traverse-carriage D is provided with the colorbox E and the printing-roller F, employed for applying the color to the yarn wound on the printing-drum A; but as this arrangement 5° is the same as in yarn-printing machines as now constructed and used further detailed description of the same is not deemed necessary.

The color applied to the yarn by the printing-roller F is rubbed or scraped into the 55 yarn by the use of rubbing devices G and G', yieldingly mounted on the traverse-carriage D and located on opposite sides of the printing-roller F, the said rubbing devices G and G' being simultaneously active and capable 60 of rubbing the color into the yarn on the travel of the traverse-carriage D in either direction.

The rubbing devices G and G' are both alike in construction, and each is provided 65 with a rubbing-block G2, having a rubbingface G³, curved from the middle downwardly in opposite directions and in the direction of the travel of the traverse-carriage D, as will be readily understood by reference to the 70 drawings, the faces G³ of the blocks G² of the devices G and G' being in alinement with the peripheral face of the printing-roller F. (See-Fig. 2.)

Each printing-block G² has a hub G⁴ se- 75 cured by a set-screw G⁵ to a cross-head H, mounted to slide up and down on posts or other guideways I, secured to the traversecarriage D. Each cross-head H rests on springs J, coiled on the posts I, and the lower 80 ends of the said springs J rest on collars J', adjustably secured by set-screws J² to the posts I, so that the tension of the springs J can be regulated by moving the collars J' farther up or down on the posts I.

The cross-head H of each rubbing device G G' is provided with depending arms H', in the lower ends of which is journaled a friction-roller H2, extending immediately below a rail K, having its ends mounted to slide up 9c and down in suitable bearings arranged on

the ends of the track C.

The rail K is provided at or near its ends with downwardly-extending links K', pivotally connected with a U-shaped lever L, ful- 95 crumed at L' on the track C. The middle bar L² of the lever L extends outside of the track C and is provided with an arm L3, pressed on by a spring N (see Fig. 3) and pivotally connected by a link O with a 100 treadle P, fulcrumed at P' on the frame B, the said treadle having a foot-piece P2 to enable the operator to conveniently press the treadle downward whenever it is desired to do so, the downward-swinging motion of the 105 treadle being limited by a suitable stop Q, at-

tached to the frame B. Now it is evident that when the foot-piece P2 of the treadle P is pressed the link O is raised, and thereby imparts a swinging motion to the lever L, so 5 that the rail K is caused to move downward and in doing so acts on the friction-rollers H² to cause the cross-heads H of the rubbing devices G and G' to slide downward on their posts I and against the tensions of the 10 springs J. The cross-heads H in moving downward carry the rubbing or scraping blocks G² along to move the rubbing-faces G³ out of engagement with the yarn on the printing-drum A. It is understood that 15 when the operator releases the pressure on the treadle P then the spring N immediately returns the lever L to its normal position, so that the rail K is raised and the springs J return the cross-heads H and their blocks G2 to 20 their normal uppermost position.

When the yarn-printing machine is in operation, the traverse-carriage D travels in the usual manner on the track C and across the peripheral surface of the printing-drum A to 25 cause the printing-roller F to apply color to the yarn in the form of a transverse stripe, and this color is rubbed or scraped firmly into the yarn by the action of the rubbing-

blocks G². It is understood that both rubbing-blocks G² are simultaneously in engagement with . the yarn on the printing-drum A and during both the forward and return travel of the traverse-carriage D, and consequently an in-35 tense rubbing action is had to insure uniform and thorough rubbing of the color into the yarn to completely penetrate the same. When it is desired to interrupt the rubbing action at any time, it is only necessary for the 40 operator to press the treadle P, as above described, to remove the rubbing-blocks G2 of both rubbing devices G and G'simultaneously

out of action—that is, away from the yarn on the printing-drum A.

It is understood that by giving the curvature described and shown to the rubbingface G3 of each rubbing-block G2 it is evident that the said face can act on the yarn when the carriage travels in either direction. As 50 one of the blocks travels in advance of the printing-roller F and the other in the rear thereof and both blocks are active simultaneously, it is evident that a double rubbing or scraping is given to the color on the yarn, and hence a thorough penetration of the color into the yarn is had.

The improvement shown and described is very simple and durable and can be readily applied to yarn-printing machines as now constructed.

Having thus described my invention, I claim as new and desire to secure by Letters

Patent—

1. A yarn-printing machine provided with a traverse-carriage having sets of posts at the 65 ends thereof, cross-heads mounted to slide on the sets of posts, springs normally retaining the cross-heads in their uppermost positions, rubbing-blocks adjustably mounted on the cross-heads, said cross-heads having spaced 7° depending arms, rollers journaled between the arms at the lower ends thereof, a rail extending across the machine above the rollers, links pivoted to the rail at each end thereof, a U-shaped lever having the arms thereof 75 pivotally connected with the links, a spring connected with the body portion of the lever for normally maintaining the track in its elevated position, and a treadle connected with the U-shaped lever for depressing the track 80 whereby to depress the rubbers.

2. A yarn-printing machine provided with a traverse-carriage having sets of posts, crossheads mounted to slide on the posts, springs for supporting the cross-heads, rubbing-85 blocks on the cross-heads, spaced depending arms on the cross-heads, rollers journaled between the arms at the lower ends thereof, a rail extending across the machine above the rollers, and means for depressing the rail 90

whereby to depress the rubbers.

3. A yarn-printing machine provided with a printing-drum, a traverse-carriage having a color-box, a printing-roller and rubbing devices, each rubbing device being yield- 95 ingly mounted and provided with a rubbingblock having a curved rubbing-face capable of rubbing the yarn on the travel of the said traverse-carriage in either direction, a rail for engaging the rubbing devices to move the 100 same simultaneously out of action, a lever pivotally connected with the ends of the said rail, and a treadle connected with the said lever.

In testimony whereof I have signed my 105 name to this specification in the presence of

two subscribing witnesses.

WILLIAM EDWARD LYFORD.
