UNITED STATES PATENT OFFICE.

JAMES SMITH LANIER, OF WEST POINT, GEORGIA.

MAIL RECEIVING AND DELIVERING APPARATUS.

No. 898,486.

Specification of Letters Patent.

Patented Sept. 15, 1908.

Application filed October 31, 1907. Serial No. 400,220.

To all whom it may concern:

Be it known that I, JAMES SMITH LANIER, a citizen of the United States, residing at | West Point, in the county of Troup and 5 State of Georgia, have invented certain new and useful Improvements in Mail Receiving and Delivering Apparatus; and I do hereby declare the following to be a full, clear, and exact description of the invention, such as 10 will enable others skilled in the art to which it appertains to make and use the same.

This invention relates to improvements in mail receiving and delivering apparatus and more particularly to the type especially 15 adapted for facilitating the receipt and delivery of mail from and to a container by a postman without requiring his dismounting.

Among the objects in view is the production of a simple and commercially practical 20 device which shall be at the same fine susceptible of ready and easy manipulation and capable of automatically assuming an out of the way position when not retained by an operator.

The invention comprises certain novel conof parts as will be hereinafter fully described and claimed.

In the accompanying drawing: Figure 1 is 30 a view in side elevation with the parts illustrated in full lines extended and in dotted lines just after being retracted and before returning to a lateral position. Fig. 2 is an edge view thereof showing the parts in full 35 lines in the normal at rest position and in dotted lines in either of the positions indicated in Fig. 1, parts being broken away for the saving of space. Fig. 3 is a horizontal section taken on the plane indicated on line 40 3—3 of Fig. 1 and looking downwardly. Fig. 4 is a transverse vertical central section taken through the support for the mail box detached from the box, the section being taken approximately on the line indicated by 45 line 4—4 of Fig. 1. Fig. 5 is an inverted plan view of the upper or swiveled portion of the parts seen in Fig. 4. Fig. 6 is a similar view of the lower or fixed portion of said parts. Fig. 7 is an enlarged detail transverse section 50 through the vertical bar of the bracket indicating the guiding cam in the top plan, the section being taken on the plane indicated by line 7—7 of Fig. 8. Fig. 8 is a vertical sec-115 engaging the respective upper and lower

tion taken on the plane indicated by line 8—8 on Fig. 7.

Referring to the drawing by numerals, 1 indicates a post or other suitable support to which is fixed a bracket plate 2. The lower end of the bracket plate 2 is bent first to a horizontal position into the horizontal por- 60 tion 3 and then bent to a vertical position into the vertical portion 4 parallel to the main body of the plate and the third time bent into the horizontal portion 5 parallel to portion 3. The upper end of the plate 3 is 65 provided with a horizontal flange or bracket portion 6, the said flange being formed with a longitudinal slot 7 having off-set portions 8 at its ends. It is to be observed that the offset portions 8 are each formed of a relatively 70 large shoulder 9 on the side of the slot 7 nearest the post 1 and a relatively small shoulder 10 on the opposite side of the slot. The horizontal portion 5 of the folded portion of the plate 2 is formed with an opening 11 and the 75 horizontal portion 3 is preferably provided with a depressed point or recess 12.

A bracket 13 is carried by the plate 2 and structions, combinations, and arrangement | consists preferably of a strap folded into a triangle having one end bolted as at 14' to 80 the vertical portion of the triangle above the lower end of said vertical portion, and between the horizontal portion 5 and flange 6 of plate 2, the said vertical portion of the bracket 13 being extended through slot 7 and 85 aperture 11 and having its lower end preferably beveled off as at 15' and extending into the recess 12. Of course in assembling or dismantling the parts it is necessary to remove the bolt 14' and spring the inclined arm 90

of the bracket 13 past the flange 6.

The upper edge of the strap of the bracket 13 is disposed in a horizontal plane when the vertical portion of the bracket is at either end of the slot 7, as indicated in Fig. 2, so 95 that said upper edge inclines upwardly in an outward direction when the vertical portion of said bracket is disposed centrally with respect to the length of the slot 7. Thus the bracket 13 is given the tendency to swing 100 laterally to the out of the way position indicated in Fig. 2 whenever the bracket is released and free to move.

A sleeve 14 surrounds the upper strap of the bracket 13 and is provided with rollers 15, 105

faces of said strap. The upper portion of | circular and then restricted at two points the sleeve 14 is fixed to a supporting bar 16 which carries the mail receptacle 17 at its outer end. Fixed to the outer end of the 5 bracket 13 is a sleeve 18 through which the bar 16 is passed. A roller 19 is preferably provided within the sleeve 18 upon which bar 16 rests. Thus it will be seen that the bar 16 is adapted to have a telescoping move-10 ment relative to the bracket 13 for adapting the receptacle 17 to be moved in and out as indicated respectively by the dotted and full lines in Fig. 1.

15 the bar 16 consists of a plate 20 riveted or otherwise suitably fixed to the bar 16 and a superposed revolubly mounted plate 21 resting upon the plate 20. The plate 21 is formed with an annular upstanding flange 22 formed 20 at its outer edge with an outwardly extending. flange 23 which latter flange is fixed to the bottom of the receptacle 17. The plate 21 is provided with a centrally disposed bearing sleeve 24 which may be suitably secured to 25 or formed integral with the plate 21 and a

similar sleeve 25 projects upwardly from the plate 20 through the sleeve 24. A cotter pin or other suitable securing means 26 is passed through the upper end of the sleeve 25 for 30 preventing displacement of the parts. It can be thus seen that the box 17 can be freely rotated at the same time being held against lateral play. In order to lock or retain the box 17 at any one or a number of positions

35 I preferably provide depressions 27, 27 in the plate 20 into which extend projections 28, 28 from the plate 21. Obviously as many depressions and as many of the projections may be employed as are preferred, and obviously 40 the positioning of the receptacle 17 may be

utilized for signaling purposes. In operation the operator simply grasps receptacle 17 or any suitably provided handle, swings the same outwardly and then 45 draws the same further outward so as to have easy access to the receptacle without having . to dismount. After making the collection or delivery the operator moves the receptacle 17 inwardly and then releases the same where-50 upon, owing to the weight of the parts and their inclined position, they swing laterally to a position parallel to the roadway, and are thus entirely out of the path of travel. In order to prevent too much vibration or 55 lateral swinging of the parts after they have arrived at the out of the way position I provide a detent on the vertical portion of the bracket 13 adapted to engage the shoulders 9 and 10 at either terminus of the slot 7, and 60 this detent preferably consists of a plate 28' which may be of thick material if desired but I preferably use comparatively thin material and therefor provide a flange 29 about the

edge of the plate as a substitute for thickness

65 of material. The plate 28' is formed partly l

producing a lateral projection 30, as best seen in Fig. 7, lying within the radius of the circle which would be described if the plate 28' were a complete disk. The material of the 70 plate 28' is stamped up from the center leaving an aperture through which the vertical portion of the bracket 13 extends and the stamped up portion is preferably riveted or otherwise suitably secured as in 31 to the 75 said vertical portion of the bracket 13. The plate 28' is positioned at that point in the length of said vertical portion which causes The connection for the receptacle 17 with | it to occupy a position within the slot 7, so that when the bracket 13 falls to the in- 80 clined position indicated in Figs. 2 and 3 projection 30, which extends outwardly in the direction of the extension of the bracket 13, will lie between the shoulders 9 and 10 and serve as a detent for preventing vibration of 85 the parts. Obviously the particular relationship of the projection 13 to the radius of the plate 28' readily enables the projection to be withdrawn from between the shoulders 9 and 10 when the bracket is swung outwardly. 90

> What I claim is: 1. In an apparatus of the class described, the combination, of a fixed bracket plate having a slotted bracket flange and an imperforate flange, a bracket pivotally engag- 95 ing the slot of the bracket flange and resting by weight upon the said imperforate flange, means for preventing vibration carried by said last mentioned bracket within said slot,

and a receptacle sustained by the last men- 100 tioned bracket.

2. In an apparatus of the class described, the combination, of a slotted bracket, a bracket comprising a continuously integral strip bent into bracket form and having a 105 vertical portion extending through the slot. of the slotted bracket, a guide plate fixed to said vertical portion within said slot and formed with a detent, shoulders being formed at the ends of said slot adapted to be engaged 110 by said detent, the upper edge of the second mentioned bracket being constructed to be disposed in outwardly and upwardly inclined planes when the said vertical portion is positioned centrally of said slot and to be 115 in horizontal planes when the said vertical portion is at either terminus of the slot, and a receptacle sustained by said second mentioned bracket.

3. In an apparatus of the class described, 120 the combination of a fixed bracket plate formed with a slot, a support, a bracket having a member extending through said slot and resting upon said support, the slot being formed with shoulders at its end, a guide 125 plate within the slot fixed to the bracket member which extends through the slot, said guide plate being formed with a laterally projecting detent adapted to engage said shoulder for preventing vibration of the bracket, 130

per edge lie in a horizontal plane when the slot engaging member of the bracket is at one terminus of the slot, and a receptacle sup-

5 ported by said bracket

4. In an apparatus of the class described, a support, a bracket having a member ex- | such angularity thereto as to extend in outtending through the slot of said bracket 10 plate and resting upon said support, the main portion of said bracket extending at such angularity with respect to the slot engaging member as to be disposed in upwardly and outwardly inclined planes when If the slot engaging member is intermediate the length of the slot, and a receptacle carried by said bracket.

5. In an apparatus of the class described, the combination, of a slotted bracket plate, 20 a support, a bracket comprising a strap of angular material bent into bracket form and having one member extending through the slot of said bracket plate, the second mentioned bracket being disposed to extend in 25 upwardly and outwardly inclined planes when the slot engaging member is intermediate the length of the slot, a guiding plate fixed to and surrounding said slot engaging member within the slot, and a re-30 ceptacle sustained by said bracket.

6. In an apparatus of the class described, the combination, of a slotted bracket plate, a support, a bracket having a member extending through said slot and resting upon 35 said support, a relatively thin flanged plate fixed to the slot engaging member and extending within the slot and adapted to guide the said member in its movement within the slot, and a receptacle sustained by said sec-

40 ond mentioned bracket.

7. In an apparatus of the class described, the combination of a slotted bracket plate, a support, a bracket having a member extending through said slot resting upon said sup-45 port, a relatively thin plate having an intermediate portion stamped out and fixed to said slot engaging member, said slot engaging member extending through the opening produced by the stamped out portion, and

the bracket being constructed to have its up- | the said plate being disposed within the slot 50 for guiding said slot engaging member in its movement within the slot, and a receptacle

sustained by said bracket.

8. In an apparatus of the class described, the combination, with a support, of a bracket 55 the combination, of a slotted bracket plate, | pivotally carried thereby and disposed at wardly upwardly inclined planes when projecting outwardly from said support, and a receptacle slidingly carried by said bracket. 60

9. In an apparatus of the class described, the combination, with a support, of a bracket pivotally sustained thereby and having its upper member spaced from the remaining portions of the bracket, a sleeve carried at 65 the outer end of the bracket, a sleeve movably engaging the upper member of the bracket, a bar fixed to said movable sleeve and movably extending through the first mentioned sleeve, and a receptacle carried 70 by said bar.

10. In an apparatus of the class described, the combination, with a bar, of a plate fixed thereto and having an upstanding cylindrical portion, a second mentioned plate rota 75 tably mounted on the first plate and formed with an upstanding sleeve surrounding the cylindrical portion of the first mentioned plate, and a receptacle sustained by the sec-

ond mentioned plate.

11. In an apparatus of the class described, the combination with a supporting bar, a plate fixed thereto having an upstanding cylindrical portion, a plate rotatably mounted upon the first mentioned plate and hav- 85 ing an upstanding sleeve surrounding said cylindrical portion, retaining means extending through said sleeve for preventing displacement of the sleeve, a plate connected therewith, and a receptacle carried by the 90 second mentioned plate.

In testimony whereof I affix my signature

in presence of two witnesses.

JAMES SMITH LANIER.

Witnesses: JOHN L. FLETCHER, EDGAR M. KITCHIN.
