C. H. J. DILG & J. O. FOWLER.

ART OF COMMINUTING FRANGIBLE ARTICLES.

APPLICATION FILED OUT. 25, 1906.

UNITED STATES PATENT OFFICE.

CHARLES H. J. DILG AND JONATHAN O. FOWLER, OF NEW YORK, N. Y.

ART OF COMMINUTING FRANGIBLE ARTICLES.

No. 899,008.

Specification of Letters Patent.

· Patented Sept. 15, 1908.

Original application filed May 15, 1905, Serial No. 260,435. Divided and this application filed October 25, 1906. Serial No. 340,465.

To all whom it may concern:

Be it known that we, CHARLES H. J. DILG and Jonathan O. Fowler, citizens of the United States of America, and residents of 5 New York, in the county and State of New York, have invented a certain new and useful Art of Comminuting Frangible Articles, of which the following is a specification, the same being a full, clear, and exact descrip-10 tion of the invention, such as will enable others skilled in the art to which it appertains to make and use the same, the present application being a division of an application for soap-supplier filed by us on May 15, 1905, 15 Serial No. 260,435.

This invention relates to a novel art by means of which solid blocks of material may be disintegrated and furnished for use in the form of fine shavings, or in a comminuted 20 condition, and in particular to a method of disintegrating chemical compounds for washing or cleansing, as soap or like articles, and it has for its object the production of a method that will accomplish the above pur-25 pose, the same being explained in connection with and by reference to a machine by means of which our process may be carried on.

With this object in view the invention consists in a certain novel art, process or 30 method which will be hereinafter described.

Figure 1 represents a side elevation of an apparatus employed in carrying out this invention: Fig. 2 is a sectional view of the same; Figs. 3 and 4 are views in detail of 35 serrated cutting or granulating means; Fig. 5 is a detail view in elevation, partly in section, of interlocking cakes of soap; Fig. 6 is a view in section, and Fig. 7 is a side elevation, with the casing partly broken away, of 40 other soap suppliers; Fig. 8 is a plan view of a cake of soap; Figs. 9 and 10 are views in detail of other cutting devices; and Fig. 11 is an end view of the soap supplier.

Like letters of reference indicate like parts

45 in all the views.

Referring particularly to Figs. 1 and 2 of the drawings, A denotes the shell or casing of a soap supplier, the same preferably consisting of a cylinder upon which is ordinarily 50 mounted the vertical tubular extension a communicating with the said shell. A bearing is ordinarily formed in the shell of the scap supplier consisting in the present em-

bodiment of a sleeve B. Within the said sleeve works a spindle C, which may be pro- 55 vided with any suitable means for operating the same, as the manually actuated crank arm C'. The inner end of the spindle C preferably carries a bevel gear D which meshes with another bevel gear D' mounted in a ro- 60 tatable relation upon the plate or partition A' of the cylinder casing A. The said bevel gear D' is ordinarily keyed to a shank or spindle E which works in a bearing in the plate or partition A' and extends up into the 65 upper portion of the tube a, with which spindle is engaged a weight E' in order that the rotation of the spindle E may cause the said weight or follower E' to revolve. The upper portion of the gravity shank or spindle E 70 works in, and is embraced in, the sleeve A3 contained in the tube a and the upper end of the said sleeve or spindle preferably projects up from the top of the casing in order to serve as a means of actuating the said shank 75 or spindle E by means of the handle or crank arm C' if desired. The sleeve or spindle A3 is provided with a longitudinal slot or keyway A4, in which works a key or pin E4 projecting from the upper part of the shank or so

spindle E. The weight E' is ordinarily provided with any suitable means of interlocking with the soap through one or more engaging means, as for example the recess e, which recess is 85constructed and arranged to preferably engage the soap and to register and interlock. with a head f in the top of the cake of soap F. Each cake of soap is not only ordinarily provided with means to engage with the weight 90 through one or more interlocking devices, as for example the recessed portion f' on one say the lower face thereof, but is also preferably furnished with other interlocking means, as projecting portions f, of practically the 95 same size and contour and ordinarily located in the upper face of the same, and constructed and arranged to interlock with the recessed portion f' of an adjacent cake of soap. One end, preferably the lower portion, 100 of the casing A is provided with a cutting device consisting of a series of scraping, shave ing or granulating devices, as for example, the serrated blades G, G', G2, the serrations of said blades being preferably arranged in stag- 195

gered order, the teeth of one of the blades, as

ting blades or knives.

The lower part of the casing head H, which is ordinarily attached to the bottom of 5 the casing A, is preferably reduced in diameter so as to converge and form a contracted opening or mouth A², which ordinarily detachable casing head is preferably interlocked, as at k, with the upper shell or casing Λ , and 10 may be fastened to the casing or cylinder A, as by means of a padlock K.

The soap supplier may be sustained by any suitable means, as for example, by means of a

supporting arm or standard I.

The depending portion of the projection e' of the weight E' will hold the body of the weight from the teeth of the cutting device, and thus prevent the same from being cut or marred, or the teeth being dulled, as might 20 occur if the knives or cutting blades were to come into actual frictional contact with the weight in cases where the soap is practically

entirely cut or worn away. In the apparatus shown in Fig. 6, the cas-25 ing A¹⁰ is provided with a partition A¹¹ through which and the top of the shell or casing works the spindle E¹⁰. The said spindle actuates the bevel gear D¹¹ fixed thereto, which meshes with another bevel gear D¹⁰, 30 the shaft C of which works in a sleeve B and carries a crank arm C'. The crank arm may, however, be attached directly to the top of the spindle E¹⁰ if preferred, as is indicated by the dotted lines. The lower and detachable 35 part of the casing, consisting of the head H10, supports the cutters G¹⁰, G¹¹, G¹², which are interlocked with the squared extension e^{10} of the spindle E^{10} . The hub h^{10} of the said head H¹⁰ is elevated a short distance above the 40 plane of the serrated blades in order to prevent the weight E' from coming at any time ! into frictional contact therewith. The interior of the casing or shell A^{10} is provided ! 45 weight and the soap, consisting in the pres- of other and equivalent soap feeding means, 110

50 E'. A recess e extending up into the weight | or casing A. 55 curb a^3 , thus forming a circular groove in lower cake of soap gets worn down to a thin 120 60 detachable, and it (or, if so desired, the parts | tirety until the engaging or intermeshing por- 125

H or H10) may be secured to the casing of the tions of the uneven face of the cake above it apparatus by means of a catch or keeper h^{20} ; are presented for abrasion. Then for a pewhich is constructed and arranged to be en- | riod of time the abrasive action is on both gaged with a pivoted spring latch h^{21} attached $\frac{1}{2}$ cakes of soap, by which construction an even 65 to the casing, and which may be released by and uniform surface is always presented to 130

G', being wider than those of the other cut-1 moving the lower arm of the catch h^{21} up wardly by means of a key inserted in the keyhole h=

> The operation is as follows: The cylinder A is charged with a suitable number of pref- 70 erably interlocking cakes of soap, the upper one of which is interlocked with a follower consisting of a plate or weight E' which may be caused to descend by its own weight or by equivalent impelling devices, as a spring, and 75 which weight is raised, when the apparatus is charged, to the position desired. The casing head is now fastened to the cylinder, upon which the apparatus is ready for use, and by turning the crank arm C', the soap and cut- 80 ting device become engaged with an abrading or scraping action in practically a plane surface and the lowest cake of soap becomes gradually worn away by reason of its contact with the cutting blades, the said disin- 85 tegrated particles of soap falling through the contracted discharge nozzle or mouth of the casing head.

As described and shown, the soap may be rotated against the stationary cutting blades, 90 or the soap may be held stationary and the cutting blades may be caused to revolve, and as the soap is preferably fed by gravity, the action of the apparatus will be uniform until the soap is practically entirely worn away; 95 or, if preferred, upon the lowest cake of soap becoming nearly ground away, it may be detached from the weight E', and a new series of cakes of soap inserted between the partially used cake and the said weight, thus 100 avoiding any waste of soap whatever.

By arranging the serrations or cutting blades so as to be of different size, the face of the soap becomes evenly ground off without leaving any very marked ridges or grooves in 105

the same. Manifestly the casing or cylinder may be placed in a slanting or horizontal position, if with means for preventing the rotation of the preferred, and the soap propelled by means ent instance of a vertical part a^{10} projecting as a spring placed on the rod between the into the chamber and registering and engag- cross piece or partition A' and the upper face ing with the groove or recess F¹⁰ of the soap of the weight or plate E', in which case the F, and a similar groove formed in the weight | mouth A^2 would be at the side of the cylinder

E' engages the soap F as before described, The advantage gained by constructing the whereby the weight and soap are held rigidly | cakes of soap with uneven interlocking or intogether. The top of the shell or casing is termeshing faces is a material saving of the preferably furnished with an inbent rim or | soap. for the reason that as the body of the which the end of the crank arm C' works disk it will not break or crumble as it is supwhen the handle is located at the top of the ported by its upwardly extending part f and apparatus. In the soap supplier illustrated i the parts surrounding the recess f' of the in Fig. 7, the upper head H²⁰ of the casing is superimposed cake. But will retain its en-

the serrated face of the cutter, and all liability of breakage and wastage of the soap cakes—such as occurs when non-interlocking or non-intermeshing cakes of soap are used 5 is overcome.

It will be observed that the blades, as G, G² and G²⁰, G²¹ have a serrated cutting edge which extends from the body slightly upwardly and is bent or inclined forwardly rela-10 tive to the vertical case of the soap shaving machine, the serrations each having ordinarily two cutting edges, one edge, as g^{22} , Fig. 10, approximately circumferentially disposed, or lying practically parallel to the cir-15 cumference of the case of the machine, and the other edge, as g^{23} , extending approximately in a radial plane or in one parallel therewith.

In respect to the blades named above, it 20 will be seen that the actual cutting lines of the edges of the teeth are those of the individual serrations, and that as some of these lines are non-radial, they give a shear cut. One series of edged teeth, as G or G21 are 25 preferably staggered in relation to another series, as G² or G²⁰, so that their circles of rotation will not coincide. We prefer to locate the serrations or teeth in lines at a distance from the axis of the cutter and to form the 30 teeth so that their pointed ends will all face the same way in the same line, in order that, no matter in which direction the cutter is turned, some of the teeth will present a cutting edge to the soap, and the teeth which do 35 not bite or cut will prevent the cutting teeth from burrowing too deeply into the soap and thus secure a fine or thin shaving.

We use the term "advancing cutting edge" to denote the presentation of one of the edges 40 of each one of the serrations to the surface of the soap to be cut, whether the cutter is moved with relation to the cake of soap, as in Fig. 4, or the cake of soap is moved over a stationary cutter, as in Fig. 2, in either of 45 which cases, each of the cutter points acts on the soap with a self burrowing cut. And inasmuch as the practically circumferentially parallel edge of a tooth limits or determines the width of the narrow shaving cut by the 50 appreximately radial or radially parallel edge, we denote the said former named edge by the term "offset". as by the said construction, each cutting edge cuts its own distinct shaving.

The blade G²⁰ in Fig. 10 has the teeth formed, as stated, so as to cut when rotated in either direction. When the said blade is rotated clockwise, for example, the width of the shaving will be limited by the width of 60 the radial or radially parallel edges g^{23} located on the left hand side of the cutter. If, however the cutter is rotated in the opposite direction, or anti-clockwise, the width of the shaving will be determined by the width of 65 the radial or radially parallel edges g^{25} .

The cutter blades we prefer to use are formed with a suitable supporting member, as a hub, or a ring or any other equivalent means with or without the use of a hub, and have, as stated, non-radially disposed blades, 70 as G²⁰ and G²¹. In Fig. 9, a plurality of blades G10, G11, G12 extend from a central supporting member or hub.

It is manifest that although we ordinarily prefer to perform our new method, art or 75 process by means of the use of a soap dispensing or soap shaving machine, such for example as the one herein described and shown, yet the said method of disintegrating soap or other frangible articles may be per- 85 formed by simple manipulation, as by holding the interlocked column of soap cakes in one hand, and by pressing against the same, a suitable instrumentality or tool, as a cutter, held in the other hand and rotating 85 either the material or the abrading device.

We do not claim in this application the machine or apparatus herein described and shown, as that is claimed in the application of which this is a division, although the same 90 is preferably employed as a part of our art or method of comminuting or reducing to a fine condition any frangible or molded, or semiplastic or sequacious material, which latter we refer to herein broadly as a frangible ar- 95 ticle. And inasmuch as a great variety of devices may be used to disintegrate the mass of material to be operated upon according to the degree of fineness or quality of the product desired, and inasmuch as the result at- 100 tained is caused by attrition or mutual contact or friction with a more or less cutting or scraping action, we designate such articles broadly as abrasive devices, although the different articles which are now in common 105 use and which may be utilized for this purpose may be specifically termed cutting, paring, scraping, grating, granulating, grinding, abrading, planing, or shaving devices, and the disintegrated or finely divided prod- 110 ucts which may be obtained by the employment of the above named reducing agencies we designate broadly as being in a comminuted condition; nor do we claim herein the cake of soap per se, as that forms the subject 115 matter of our application for a cake of soap, filed December 29, 1906, Serial No. 350,065, the same being a division of our application for a soap supplier filed May 15, 1905, Serial No. 260,435.

The essential feature of our invention of progressively reducing solid material consists in assembling a series or plurality of cakes or units so as to form a comparatively solid column or bar, the opposing or engag- 125 ing faces of the units being so formed that, when engaged, there are preferably no interstices or open spaces between them, and, also so that their juncture shall be so positioned as regards the abrasive device that, when 130

presented endwise to the latter, different points of said juncture will lie at various distances from said abrasive device.

We prefer that the opposing or engaging faces shall be of an uneven contour, which shall be non-correspondent in form with that of the abrasive device, but it is essential that the operative surface of the abrasive device shall form one or more angles with the line of division, or the juncture, between the units, or with the ends thereof, in order to constitute what we term, an endwise engagement.

What we claim as our invention is:

The art of progressively reducing solid ma-15 terial, which consists essentially in assembling into a column or series a plurality of units having engaging faces; and presenting such column or series endwise to the action

of an abrading device, the engaging faces of the units and of the operative part of the ab- 20 rading device being non-correspondent in form, so that different points of the juncture of the units shall lie at various distances from the said operative part, whereby it commences the reduction of a succeeding unit of 25 the series before it has completed that of the preceding one.

In testimony of the foregoing specification we do hereby sign the same in the city of New York, county and State of New York 30

this fifteenth day of October 1906.

CHARLES H. J. DILG. JONATHAN O. FOWLER.

Withesses:

ROB. SCHWARZ, S. HERZOG.
