J. F. WARE & T. W. RUNDLE. AUTOMATIC FLUID CONTROLLED VARIABLE TIME EXPOSURE VALVE MECHANISM

J. F. WARE & T. W. RUNDLE. AUTOMATIC FLUID CONTROLLED VARIABLE TIME EXPOSURE VALVE MECHANISMFOR PHOTOPRINTING MACHINES.

UNITED STATES PATENT OFFICE.

JAMES F. WARE AND THOMAS W. RUNDLE, OF DENVER, COLORADO, ASSIGNORS TO THE AUTOMATIC PHOTOGRAPH PRINTING MACHINE COMPANY, A CORPORATION OF ARIZONA TERRITORY.

AUTOMATIC FLUXD-CONTROLLED VARIABLE-TIME-EXPOSURE VALVE MECHANISM FOR PHOTOPRINTING-MACHINES.

No. 899,235.

Specification of Letters Patent.

Patented Sept. 22, 1908.

Application filed March 12, 1907. Berial No. 361,970.

To all whom it may concern:

Bo it known that we, JAMES F. WARE and THOMAS W. RUNDLE, citizens of the United States of America, residing in the city and 5 county of Denver and State of Colorado, have invented a new and useful Automatic Fluid-Controlled Variable-Time-Exposure Valve Mechanism for Photoprinting - Machines, of which the following is a specifica-

10 tion. Our invention relates to a new automatic fluid controlled variable time exposure valve mechanism for photoprinting machines; and . the objects of our invention are: First, to 15 provide a variable time operating valve for automatically regulating and governing the internuittent operating movement of the printing mechanism of photographing machines, that require a regular intermittent 20 period of time in which to make an exposure and to perform an operative printing movement. Second, to provide a valve that moves automatically through its operative 25 that can be varied to any predetermined quick or slow movement desired. Third, to provide a fluid controlled variable time operating valve that is adapted to control the operative action of doors, shutters, backs of 30 printing machines, and other reciprocating devices. We attain these objects by the inechanism illustrated in the accompanying drawings, in which:

Figure 1, is a perspective view of a valve. 35 embodying our invention. Fig. 2, is a sectional elevation through the center of the valve. Fig. 3, is a sectional elevation of a photographic printing cabinet, showing the application of our improved variable time 40 operating valve to the time control and the automatic release of its printing pad holding back or door, the said door being closed, and the valve plunger rod released and in the act of descending. Fig. 4, is an end view of the is cabinet showing the valve and operating mechanism connected therewith, the door of the cabinet being removed. Fig. 5, is a perspective view of the upper portion of the valve, and mechanism connected therewith. 50 And Fig. 6, is a front view of a fragment of the cabinet, showing the mechanism operated by the latch of the pad-holding door,

for releasing the plunger rod, simultaneously, with the latching of the door.

Similar letters of reference refer to similar 55

parts throughout the several views. Referring to the drawings, the numeral 1, designates the cylinder of our valve. This cylinder is mounted on any suitable supporting base 2, to which it may be threaded or 60 otherwise secured, or with which it may be integrally cast. We preferably however, cut a thread on the lower end of the cylinder and screw it into a threaded recess 3, formed in the base plate. This cylinder is provided 65 with a piston bore 4, which extends from one end to the other end. At the lower end of the cylinder and at diametrically opposite points, inlet and outlet ports 6 and 7 are formed at the bottom of the cylinder, and 70 outlet and inlet ports 8 and 9 are also formed at the top of the cylinder. The port 6 is an inlet port into the cylinder, and the port 7 is an outlet port out of the cylinder on the opposite side of the port 6, while the port 8 is an 75 movement with a steady, even movement, outlet port from the cylinder at its top directly above the inlet port 6, and the port 9 is an inlet port into the cylinder directly. above the outlet port 7... These two oppositely arranged sets of ports 6 and 8, and 7 80 and n, are connected together on opposite sides of the cylinder by tubes or pipes 10 and 11, which are preferably cast integral with the cylinder. The inlet port 6 is controlled by any suitable automatically operating inlet 85 valve, but we preferably employ a common stap valve 12, which is secured at one side to the port in a position to swing open under the pressure of the inflowing fluid, and to close the port when the fluid pressure is 90 forced down in the cylinder. The cylinder. inlet port 9, is also provided with a valve 13, and a valve seat 14, which are located in the top of the vertical portion of the tube 11. The valve is preferably of the plug type and 95 fits against a taper seat formed around the interior of the tube. A valve stem 15 extends from the valve up through the tube and through a plug 16, which is screwed into a threaded aperture 17, formed in the top of 100 the tube 11. This plug is provided, with a threaded aperture 18, and the valve stem is provided with an enlarged portion 19, the upper end of which is threaded into the

threaded aperture in the plug. This plug is also provided with a stuffing box 20 and a gland nut 21 is screwed on top of the plug over the stuffing box, an aperture being 5 formed through the stuffing box, and through the gland nut in line with the aperture in the stuffing box, through which the valve stem projects, and suitable packing is placed in the stuffing box and gland around the valve 10 stem and the gland is adjusted to pack the stem against leakage. At the top of the valve stem a pointer 24 is secured, and an index dial 25 is secured beneath the pointer, which is provided with a number of index 15 lines arranged radially around it, and which | sides of the cabinet to allow easy entrance to 80 indicate equal intervals of the circular movement of the pointer in moving the valve stem and valve from a closed to a fully opened position.

A piston 22 of suitable weight, is reciprocally mounted in the cylinder and is provided with suitable packing rings 23, and a piston rod 26 is secured at one end to the piston, and extends up through a cylinder head 28 which 25 is threaded to the upper end of the cylinder. A pin 27 extends upward from the base plate, to limit the downward movement of the piston, and a pin 27' extending upward from the top of the piston, contacts with the 30 head 28, to limit the upward movement of the piston. The cylinder head 28 is provided with an axial aperture through which the piston rod passes, and also with a packing box 29, a packing gland 30, and a packing mate-35 rial. On the piston rod above the gland we mount slidably a crosshead 31, the opposite ends of which are slidably mounted on two vertical rods which are secured at their lower ends to the top of the cylinder head.
On these rods expansive coiled springs 32 are placed, the lower ends of which rest on top of the cylinder head, and their opposite ends bear against the under side of the ends of the crosshead. These springs are of sufficient 45 length to permit of a resilient movement equal to the stroke of the piston in its cylinder. Upon the piston rod a collar 33; is adjustably secured by a set screw 34. This collar is positioned on the piston rod to be en-50 gaged by the crosshead when the crosshead and also the piston is at the lowest point of its downward stroke, and when the crosshead is released the piston is raised to the top of its upper stroke by the engagement of 55 the crosshead with this collar through the

We have preferably illustrated our invention applied to our new photographic print-155 ing muchine, for which we have especially in-

or pad liolding back or other thing or machine or device that is to be operated by the

valve.

medium of the crosshead springs. This

crosshead is moved down to the limit of its

mechanism connected to the door or shutter

vented it; and in which we have adapted it to automatically control the variable time exposures required to print different pictures from different negatives, and for vignetting printing work; and we preferably carry out 70 this feature of our invention in the following manner: This printing machine consists of a cabinet 35, preferably mounted on legs, and preferably of a height to be operated by an operator standing beside it. This cabinet pref- 75 erably consists of a square box-shaped frame inclosing a large chamber in which an electric or suitable light is placed. Hinged doors 36 and 37 are placed in the opposite the cabinet from its opposite sides, and in the central portion of the top of the cabinet a glass door 38 is hinged to lift and swing upward, and to the under side of the top of the cabinet at the sides of this glass door several 85 slide-ways 39, are placed, in which the vignetting sheets are placed. The negatives and sheets of photo-printing paper are laid on top of the glass door. At the rear or hinged end of the glass door, a pad pressure shutter 90 or door 40 is hinged, which is adapted to press a suitable cushioning pad against the print paper and smoothly press it against the glass door. This pad pressure shutter is preferably made in two halves which are 95 hinged together, a spring being arranged to extend from one half door to the other.

A pneumatic cylinder and piston 41, areconnected to the shutter and top of the cabinet to cushion the opening movement of the 100 shutter. This divided shutter and the pneumatic cushioning cylinder and piston do not. however, form an essential part of my present invention, and a fuller description of their exact construction and arrangement is 105 unnecessary, as any suitable single piece pad pressure hinged shutter can be used instead. of the divided shutter illustrated, it only being necessary to operatively connect it to the oil valve in such a manner that the shutter is 110 released and is arranged to open automatically and to be arranged to be instrumental in moving the piston of the oil valve down to the limit of its downward stroke when it stands fully open; and in carrying out this 115 feature of our invention we preferably secure a segment of a sheave 43 to the center of the width of the back of the shutter adjacent to its hinged end, to which one end of a cord or chain 44 is attached, the opposite end of 120 which is extended over a small sheave pulley 45, journaled in a lug 46, which is secured to downward stroke by means of any su able. the top of the cabinet. From this pulley the cord extends down through an aperture in the top of the cabinet into its light chamber, 125 and to a sheave pulley 47 journaled in a lug 48, secured to the floor of the cabinet under which it passes and then extends upward and is connected to a lever 484, which is the crosshead actuating lever of the oil valve, one end 130

899,235

of which is pivotally secured to a lug 49,] which is secured to one of the inside walls of the cabinet.

The oil valve is preferably set on the floor 5 of the cabinet close to the opposite side of the chamber of the cabinet, from the side the pivoted end of the lever is secured to, and the opposite end of the lever 48^A extends to the valve and its end is bifurcated to 16 form a fork 50, which struddles the piston rod and its collar 33, and these ends rest on a couple of blocks 51, which are secured to the top of the crosshead. The top surfaces of the fingers of the forked end of the lever are rounded to fit into these recesses, which arrangement holds the end of the lever 484 in constant bearing engagement with the crossco head, as its springs hold it under constant. upward pressure, and the closing weight of the shutter through the medium of the cord is pulling the lever down against the block with a constant downward pressure, the 25 weight of the shutter being directly on the lever, and the crosshead springs are strong enough to raise the lever, and through the medium of the cord to raise the door and normally hold it in an opened position, as 30 shown in Figs. 3 and 4.

When printing photos, the shutter is shut, that is pressed down against the glass door by the hand of the operator, and is locked there by an automatically operating lock, 35 which we will presently describe; and this downward closing movement of the shutter pulls on the cord and pulls the lever 48⁴ down and it presses the crosshead down on its springs, and when the shutter is locked 40 down against the glass door the lever holds the crosshead down to the limit of its operative downward movement under the expansive tension of its springs, until the shutter is unlocked by the piston at the end of its 45 downward movement. This downward traveling movement of the piston begins the instant the shutter is closed and locked in a closed position, as the piston is normally at the upper end of its vertical stroke, as it is. 50 raised and held there by the crosshead's engagement with the collar 33 by the expansion tension of its springs.

While any suitable character of a locking mechanism that the downward movement of 55 the oil valve's piston can release at the end of its downward stroke, can be employed to lock or latch the shutter in a closed position, we preferably carry out this feature of our invention in the following manner: The front 72, which are engaged by them, the pin 71 and end of the shutter is provided with a hand being adapted to lock the knob and stem 125 knob 53, which is secured to the upperend of | lock meel anism to the spring catch 74 when a stem 54, which extends vertically and re- | the shutter is shut, and the pin 72 being arciprocally through and beyond a hub 55, ranged to release the piston the instant the formed on the top of the shifter. This hub shufter is locked, allowing it to descend in

sive spring is placed, which is arranged to normally field the stem and knob at the top of its vertical movement. A plate 564 is secured to the top of the cabinet and this stem extends down through an aperture 57 in the 70 top of the plate and cabinet, into a lock 58. A hook 59 is secured to the under side of the shutter in front of the hub, and depends therefrom and extends through an aperture 60 formed in the plate 56 and the top of the 75 cabinet. The lock 58 comprises a supporting plate 61, which is secured to the under side of the top of the cabinet. A yokethese blocks are preferably provided with shaped clip 62 is secured to the plate, to 15 contaved recesses 52, and the lower side of | which a right-angled latch hook 63 is pivot- 80 ally attached intermediate of its ends; one end of this latch stands vertically and is provided with a hook arranged to hook over the hooked end of the depending latch of the shutter. The opposite end of this latch ex- 85 tends to and is pivotally connected to a verticaliz-reciprocating toothed rack bar 64,. which is reciprocally mounted in a slideway 65, secured in the plate, the top end of which lies in the path of and is engaged by the de- 90 scending knob stem of the shutter, when it is closed against the top of the glass door of the cabinet.

The gear teeth of the rack bar mesh with the teeth of a segment of a pinion 66, which 95 is pivotally secured to the plate. An arm 661 is secured to this pinion, the outer end of which is pivotally connected to one end of a lever 67, the opposite end of which is pivotally connected to one end of a crank lever 68. 100 the opposite end of which is secured to one end of a shaft 69, which is rotatably journaled in depending brackets 70, which are secured to the under side of the top of the cabinet. The opposite end of this shaft is 105 provided with two pins 71 and 72, which are positioned to stand vertically downward when the shutter is open, being held in that position by a spring 73, which is coiled around the shaft and fastened at one end to 110 it, its opposite end being secured to the adjacent bracket 70. The lower end of the arm 66^A is adapted to be connected to a mechanism used in printing, that does not form any part of my invention. These two 115 pins 71 and 72 are adapted to engage two spring catches 74 and 75, which are made of sheet spring metal. These spring cutches are secured at one end to the under side of the top of the cabinet, and in a position to 120 depend on opposite sides of the piston rod of the oil valve, and opposite to the shaft 69, and in the oscillating path of the pins 71 and 65 contains a chamber 56, in which an expan- lits cylinder, and they are arranged to per- -10

form these functions in the following manner: The spring catch 74 is provided with a rightangled off-set that is positioned adjacent to its lower end to catch the pin 71 at the upper t end of its upward oscillating movement. A curved terminal chd 78 is formed on the end of the spring, which is arranged to be engaged by the pin and moved back enough to allow the step to spring back under the pin 10 when it is moved upward by the movement of the lock and the oscillating movement of the shaft and pins, due to the closing of the shutter, which will be more fully described hereafter; thus locking the pin and shaft and 15 the right-angled latch of the lock to the latch of the shutter and holding it locked until released by the piston at the end of its downward stroke, which act on the part of the piston will be presently explained. The lower 20 end of the spring catch 75, is also provided with a right-angled step, and also with a terminal curved end portion adapted to be engaged and pushed back by the pin 72, as it is moved upward by the oscillating move-25 ment of the shaft. The step however, is adapted to act as a saddle for a pin or arm 79, that projects from a hub 80, which is adjustably secured to the piston rod of the oil valve. This hub is also provided with a 30 second arm 81, which we term a guide arm, which projects towards the adjacent side of the cabinet where it enters a guide-way slet 82, formed in a bracket 83, which is secured to the side of the cabinet. This guide-way 35 slot and the guide arm hold the piston against turning; consequently the hub arm 79 will move vertically and reciprocally in the same plane and will always be seated in the offset step of the spring lever 75, when it 40 is raised to the top of its upward stroke. A hub 84 is also adjustably secured to the piston rod above the hub 80, which is provided with a projecting arm 85, that is positioned to engage the end of a projecting pin 86, 45 which is secured to the spring catch 74, in the downward path of the arm 85. The arm 85 strikes the pin 86, at the end of the piston and piston rod's downward stroke, and moves the spring so that its step is forced from 50 under the pin 71, which is under a constant downward pressure, due to the spring 73 on the shaft 69, and the minute the pin 71 is released the coiled spring on its shaft forces the shaft to oscillate and turn the pin down 55 and this movement of the shaft partially rotates the gear segment through the medium of the lever at the end of the shaft, and the gear segment raises the rack bar which throws the hook of the latch out of engagement with the 60 hook of the shutter and releases the shutter, which instantly springs up open through the medium of the crosshead springs, the forked lever, and cord, and as the crosshead springs upward it strikes the collar 33 and lifts the 65 piston rod upward with it to the top of its I the valve port; thus if the index is set at ten 130

upward stroke. The oil valve's valve stem 15 extends up through the top of the cabinet and through the index disk 25, which is secured to the top of the cabinet. This index plate is a circular disk that is graduated into 70 a plurality of equal divisions, representing seconds and minutes, throughout its circumference, the minutes represented being the few usually required for the exposure in printing photographic pictures. To the top 75 of the valve stem the index finger 24 is secured, and to the index finger a hand-grasping knob 24⁴ is attached, by which the index finger may be turned to any desired point of the graduated index disk.

The operation of our fluid controlled variable time exposure valve for photographic printing machines, is as follows: The printing machine is adapted to print in duplicate copies of photographs; consequently the dif- 85 ferent negatives of different pictures from which copies are to be printed would require different lengths of time exposures, and when it is desired to print a large number of copies. from a negative, the index finger is set at a 90 point of the index corresponding to the number of seconds or a minute and seconds or two or more minutes that the operator thinks will be the length of time required for the exposure required to print the picture; 95 and the length of time for the exposure can be accurately adjusted by making a few tests and moving the index finger to either increase or diminish the time of the exposure until the printed copies are found to have 100 the length of time exposure necessary to make them print satisfactorily. When printing photographic pictures, the inside of the cabinet is provided with a suitable light, and is otherwise arranged to print pictures. We 105 do not however, illustrate or describe this feature, as it does not form a part of our present invention. The oil valve cylinder is made of a length and capacity suitable for the size of printing machine it is to be used 110 on, and it is filled through an aperture 87 by removing a plug 88, with any suitable oil or other fluid, which when the piston descends flows through the tube 11, and valve 13, and port 9, into the top of the cylinder, and onto 115 the top of the piston; when however the piston is raised the oil flows through the inlet port 6 into the cylinder and under the piston and into the tube 11. The cylinder should be made long enough to permit the piston to be 120 three or four or more minutes in making its full downward latch releasing stroke with a valve opening sufficient to insure an even steady movement of the piston. The turning of the index finger turns the valve stem 15, which 125 being threaded to the nut 16, lowers or raises the valve 13 either towards or from its seat in the compartment 11 of the cylinder, and thus allows more or less oil to flow through

seconds, the valve port is opened to allow just enough oil to flow through the port to allow the piston rod to be ten seconds in traveling its downward stroke from the time 5 it is released by the closing of the shutter until it releases the shutter at the end of its downward stroke. If the exposure required is one minute, the index finger is moved to the one minute point, which opens the valve 10 far enough to allow the oil to flow fast enough to allow the piston rod to move slowly enough to be one minute in releasing the shutter after it is closed and lacked to the valve. Consequently, after the operator 15 has adjusted the time index to secure the desired time exposure, he simply closes and locks the shutter to the valve after each printing exposure, and the valve automatically holds the shutter closed and exposes 20 each picture exactly the same length of time until as many pictures are printed as desired. And when a change is made to a negative requiring a longer time of exposure, the index must be readjusted to open or close 25 the port of the oil valve to allow the piston and piston rod to make their downward operative movement in the time required, when the valve will automatically hold the shutter closed and release it at the end of the 30 time required for the exposure, as often as the shutter is locked to it.

Our invention is simple, reliable, and enables photographic pictures to be quickly and accurately duplicated to any number 35 required, and our invention contemplates other characters of machinery and to perform other uses.

Having described our invention, what we claim as new and desire to secure by Letters Patent, is:

1. In an automatic fluid controlled variable time exposure valve mechanism, for is photo-printing machines, the combination with a suitable cabinet, provided with a swinging shutter, and a spring-controlled latch mechanism, of a valve comprising a vertically disposed cylinder provided with a nort on each side, a piston reciprocally mounted in said cylinder, a valved inlet from one port into the bottom of said cylinder, and outlet valve leading from the top of the other port into the top of said cylinder, an index controlled valve stem attached to said outlet valve, means including a spring | adjacent to the opposite end of said lever, a controlled latch for locking said shutter in a | crosshead reciprocally mounted on said cylincluding a projecting arm on said piston ar- move said crosshead in one direction of its ranged to release said shutter's latch at the reciprocal movement, the closing weight of end of the piston rod's downward stroke, as specified.

able time exposure valve mechanism for free end of said lever being moved by the

of an oil valve, comprising a cylinder and its ports, provided with a body of oil, a piston and piston rod arranged to move on its downward stroke in said body of oil by their weight, and an oil outlet valve and valve 70 stem, with a cabinet, a shutter hinged thereto, and arranged to be swingingly closed against said cabinet, means for latching said shutter against said cabinet, means connected with said oil valve for engaging said 75 latch and releasing said shutter, resilient means on said valve for holding said shutter. under a constant opening movement tension.

3. In an automatic fluid controlled variable time exposure valve mechanism for 80 photo-printing machines, the combination with the cabinet, the swinging shutter hinged thereto, and means for latching said shutter closed against said cabinet, of a fluid controlled valve connected to said cabinet and 85 comprising the cylinder provided with a body of oil, the piston and piston rod, and the manually operated valve, said piston being arranged to move in said body of oil on its downward stroke by its weight, resilient 90 means connected to said cylinder for raising and holding said piston at the top of its upward stroke, means including a lever and a cord connected with said shutter, and said cabinet, for holding said shutter under a con- 95 stant opening tension, and means connected with said piston rod for releasing said shutter's latch, and shutter, at the end of its downward stroke.

4. In an automatic sluid controlled vari- 100 the use of the oil valve and an operative able time exposure valve mechanism for locking and releasing mechanism for use for | photo-printing machines, the combination of a vertically disposed cylinder having valve-controlled ports, and provided with a supply of liquid, a reciprocating piston and 105 piston rod in said cylinder adapted to reciprocate in said fluid, and a manually controlled valve arranged to control the flow of fluid in said cylinder to permit different speed inovements of said piston and piston 110 rod on their down stroke in said cylinder, with a cabinet provided with a glass exposure plate, a shutter hinged to said cabinet and adapted to be closed against said exposure plate, means including a latching mech- 115 anism for locking said slitter closed to said exposure plate, a reciprocating lever secured at one end in said cabinet, a cord connected at one end adjacent to the hinged end of said hinged shutter and secured at its opposite end 120 closed position on said cabinet, and means | inder and piston rod, springs arranged to reciprocal movement, the closing weight of 125 said shutter being arranged through the medium of said cord to hold the free end of said 2. In an automatic fluid controlled vari- lever against said crosshead, and the said 65 photo-printing muchines, the combination closing movement of said shutter to force 130

said cross-head down against its springs whereby said crosshead exerts a constant opening pressure on said shutter, means including a latching mechanism connected to 5 said shutter and cabinet for locking said shutter closed against said exposure plate, a collar on said piston rod engaged by said crosshead, said piston rod being adapted to be raised to the top of its upward stroke by 10 the upward springing movement of said crosshead when said shutter is unlatched · from its closed position over said exposure plate, means connected with said piston for engaging said latch mechanism and releas-15 ing said shutter, and an index plate arranged on said cabinet and arranged to determine the manual opening movement of said valve to permit said piston rod to fall on its downward stroke in said fluid and release said 20 shutter latching mechanism.

5. In an automatic fluid controlled variable time exposure valve mechanism for

photo-printing machines, the combination of a cabinet provided with a glass exposure 25 plate, a shutter hinged to said cabinet to swing down and be closed over said glass exposure plate, a hook depending from the free end of

said shutter, a sliding knob spring controlled

in one direction of its movement extending 30 through said shutter, a latch mechanism attached to said cabinet comprising a hook, a toothed rack bar attached to said hook and arranged in the path of said sliding knob, and adapted to move said hook to engage

35 and lock to the hook of said shutter, a gear segment in engagement with said rack bar provided with a projecting arm, a shaft journaled to said cabinet so as to be oscillated and provided with a projecting pin, a crank

40 arm on one end of said shaft, a lever connected at one end to said gear segment's arm and at its opposite end to said shaft's crank arm, and a lever connected to said cabinet at one end and to said shutter adjacent to its

45 opposite end, with a fluid valve comprising a cylinder having independent ports connecting its opposite ends, an automatically operating valve controlling the entrance of one of said ports into the bottom of said cylinder,

so a manually operated valve arranged to control the outlet of the other port into the top of said cylinder, a reciprocating piston and piston rod in said cylinder, a collar on said piston rod, guides on said cylinder, a cross-

55 head slidably mounted on said guides and on said piston rod between said collar and said cylinder, expansive springs on said guides between said crosshead and said cylinder, said crosshead being arranged in engagement

60 with and adapted to hold said shutter's opening lever and said shutter under a resilient opening pressure when said shutter is locked to said latch, a spring blade arranged to receive and hold the projecting pin of said

65 latch's oscillating shaft when said shutter

is closed, a projecting pin on said piston rod arranged to engage said spring and release said latch's oscillating shaft's pin, a projecting pin on said piston rod, a spring blade arranged to engage said piston rod's projecting 70 pin, and hold said piston rod at the top of its upward stroke, a pin projecting from the oscillating shaft of said latch and arranged to engage said spring and release said piston rod, and a valve opening movement index 75. arranged adjacent to said manually operated valve stem, substantially as specified.

6. In an automatic fluid controlled variable time exposure valve mechanism for photo-printing machines, the combination 80 with the cabinet, the exposure plate, and the hinged shutter arranged to swing down over said exposure plate, a latch mechanism on said cabinet arranged to latch said shutter. down against said exposure plate, the lever 85 and cord attached to said shutter for opening said shutter, and an oil valve in said cabinet having a vertical piston adapted to move on its upward stroke by an expansive spring arranged on said valve and piston, and adapted 90 to operate said lever and cord to normally hold said shutter open, said piston being adapted to move on its downward stroke by its weight, means connected to said piston rod for releasing said shutter's locking mech- 95 anism at the end of its downward stroke, and a manually operated valve provided with a variable movement index attached to said oil valve and arranged and adapted to control said oil valve to cause said piston rod to move 100 on its downward strokes at different rates of speed whereby said shutter may be locked to said cabinet and valve for different predetermined periods of time and be automatically. released at the end of a set time by the down- 105 ward stroke of said piston rod.

7. In an automätic fluid controlled variable time exposure valve mechanism for. photo printing machines, the combination of the oil valve, the cabinet, the shutter, means 110 for connecting said shutter to said oil valve to normally hold said shutter open, means including a latch mechanism connected to said cabinet for locking said shutter closed, and means connected with said valve for engag. 115 ing said latching mechanism and for operatively releasing said shutter at different predetermined periods of time after said shutter is latched to said cabinet.

8. In an automatic fluid controlled vari- 120' able time exposure valve mechanism for photo-printing machines, the combination with the cabinet provided with a glass exposure plate and shutter hinged to said cabinet at one end, and adapted to swing down over 125 said exposure plate, said shutter being divided into two halves hinged together, resilient means for holding said halves in operative relation to each other, a latch mechanism arranged partially in said cabinet and partially 13

on the free end of said shutter, a fluid-con- table time exposure valve mechanism for rod, spring controlled means for moving said 5 piston and means for locking said piston and | ports connecting its opposite ends, a weight- 10 stroke of its reciprocal movement, said piston ! being weighted to move automatically through said oil valve on the opposite stroke to of its reciprocal movement, a manually regulated valve in said oil valve for regulating the | cylinder, a valve stem connected to said outspeed and time of the weighted stroke of said let valve and threaded to the top of said cy!piston in said fluid-controlled valve, means | inder and arranged to be turned in its threadincluding springs connected to said piston ed seat to move said plug valve to open or 15 and valve for raising and releasing said shutter's and cabinet's latching mechanism, at the end of its weight actuated stroke, and means connected with said shutter and with the spring actuated means for moving said 20 piston and its piston rod to the end of one of its reciprocal movements for normally holding said shutter under constant opening movement tension, and means including a cylinder and a piston for cushioning the open-25 ing movement of said shutter.

9. In an automatic fluid controlled variable time exposure valve mechanism for - photo-printing machines, the combination of the cabinet, the oil valve, and the shutter 30 divided in two halves hinged together, one part of said shutter being hinged to said cabinet, a resilient cushioning device on said cabi-· net connected to said shutter and arranged to cushion the opening movement of said shut-35 ter, the cord and lever for connecting said shutter to said oil valve, the latch mechanism arranged to lock said shutter to said cabinet in a closed position, and means connected to said oil valve for releasing said latch mech-40 unism and for permitting the operation of said cord and lever of said shutter to open the same after predetermined periods of time.

10. In an automatic fluid controlled variable time exposure valve mechanism for 45 photo-printing machines, the combination of the fluid controlled oil valve comprising the cylinder and ports, the piston and piston rods reciprocally mounted in said cylinder, the inlet valve, the outlet valve and valve 50 stem provided with an opening movement index, with the cabinet, the glass exposure plate, and the shutter hinged to said cabinet and adapted to swing to cover said glass exposure plate, a latch mechanism connected 55 to said shutter and said cabinet and arranged to lock said shutter closed to said cabinet, a spring controlled mechanism arranged to move said piston to the end of one of its reciprocal movements and operatively con-60 nected to said shutter to normally hold said shutter under a constant opening movement pressure and means connected to the piston rod of said oil valve for releasing the latching mechanism of said shutter.

11. In an automatic fluid-controlled vari- | mined periods of time.

trolled valve mounted in said cabinet pro- photo-printing machines, the combination vided with a reciprocating piston and piston | with a photo-printing cabinet of a vertically positioned cylinder mounted therein, having piston rod in said oil valve at the end of one | ed piston and piston rod in said cylinder, a swinging inlet valve from one of the said cylinder ports into the bottom of said cylinder, a plug valve arranged to control the outlet of the other port into the top of said 75 close the port leading to the top of said cylin- 80 der, a body of oil in said cylinder and ports, a collar on said piston rod, guide rods secured to said cylinder, expansive coiled springs mounted on said guide rods, a cross head slidably mounted on said piston rod and guide 85 rods, and resting on said guide rods' springs, and adapted to normally force said piston rod to the top of its vertical stroke and to be moved down on its guide rod springs far enough to permit said piston rod and piston 90 to travel down in said cylinder to the end of its downward stroke and when released to force said piston rod up to the top of its upward stroke, a projection on said piston rod, a spring lever connected to said cabinet and 95 arranged to engage the projection of said piston rod and hold said piston and rod at the top of its upward stroke when raised there by the spring movement of said crosshead; a cooperating latching mechanism connected 100 to said shutter and said cabinet, means including a lever connected to said cabinet and shutter and arranged in engagement with said piston rod's crosshead, and adapted to move said crosshead down when said shutter 105 is closed down and latched to said cabinet and to compress its spring far enough to allow said piston rod to move to the end of its downward stroke, a spring lever connected to said cabinet and arranged to engage and 110 lock said shutter's latch mechanism, and means connected to said piston rod for engaging said cabinet's spring lever at the lower end of its downward stroke, and releasing the .cooperating latching mechanism of said shut- 115 ter and cabinet and thereby allowing said shutter to be forced open by the upward springing movement of said spring actuated crosshead and said shutter's connecting lever and thereby throwing said piston rod again to 120 the top of its upward stroke, and means including an index for determining the opening. and closing movement of said oil valve's outlet valve and the time of the falling stroke of said piston rod whereby said piston rod may 125 be made to move on its downward shutter releasing stroke in different predetermined periods of time and said shutter is kept closed and released at the end of different predeter-

120

12. In an automatic fluid controlled variable time exposure shutter releasing valve mechanism for photo-printing nuchines, the combination of the cabinet provided with the 5 glass exposure plate and the swinging shutter, the cord and lever connected to said shutter and cabinet, the reciprocating hand operated knob and latch hook at the free end of said shutter, the latch mechanism attached to 10 said cabinet and arranged to engage the hook of said shutter, with the fluid controlled valve comprising the cylinder, the piston and piston rod, the outlet valve and valve stem operatively arranged to engage said latch mech-15 anism and open said shutter, and means for controlling said valve to hold said shutter closed and to release it at different predetermined periods of time.

13. In an automatic fluid controlled vari-20 able time exposuré shutter releasing valve mechanism for photo-printing machines, the combination of the cubinet, the shutter hinged to said cabinet, the hook latch on said shutter, the tilting right angled latch on said 25 cabinet, the rack-bar pivoted to said tilting latch and the rock shaft provided with projecting pins, the spring lever secured to said cabinet and arranged to engage said rock shaft's projecting pins, the spring controlled 30 reciprocating knob on said shutter arranged to engage said rack-bar and cause said tilting latch to engage said shutter's hook and simultaneously tilt said rock shaft and cause its projecting pins to engage said cabinet's 35 spring lever, and lock said shutter to said cabinet, and the fluid controlled valve provided with a variable time movement piston and an adjustable operating valve.

14. In a fluid valve controlled mechanism 40 for photo-printing machines, the combination with a cabinet of a pad holding shutter hinged thereto, comprising two members united by a hinge connection; a catch on said shutter; a hook pivoted to the cabinet, for 45 engaging the catch; a spring controlled rod connected at one end through a system of levers and a rack and pinion with said hook and having a finger at the other end; a spring catch adapted to hold said finger 50 when said rod is turned, a liquid operated valve for releasing said finger having a piston rod which is held normally in a raised position; and an arm on said piston rod for ergaging said spring catch as the piston rod 55 descends; a knob on said shutter for operating the rod and pinion to simultaneously lock the shutter, turn the rod to cause its finger to engage the spring catch, and release the piston rod, and springs for raising said shutter when the latch is released.

15. In a fluid valve controlled mechanism for photo-printing machines, the combination with a subinet of a pad-holding shutter hinged thereto comprising two members united by a hinge, a latch for locking said 65 shutter against the top of said cabinet, springs for normally holding said shutter open; a spring controlled rod connected at. one end with said latch and having a finger at its other end which is engaged by and held 70 by a spring catch when the rod is turned; a fluid operated valve having a weighted piston provided with a rod having a projecting arm for engaging said spring catch on the descent of the piston; and means for simul- 75 taneously latching the shutter and releasing the piston and means for cushioning the up-

ward movement of the shutter.

16. In a device as specified, the combination with a cabinet having a hinged pad 80 holding shutter comprising two members hinged together, of means for latching and . for automatically releasing said shutter, comprising an oil valve having an oil cylinder, a weighted piston in said cylinder hav- 85 ing an extended rod; a spring catch, a finger on said piston rod which normally engages said catch and holds said piston elevated; an arm on said piston rod; a spring catch having a pin which is adapted to be engaged 90 by said arm, a spring controlled rod, having fingers, one of which is engaged by said last mentioned catch when the rod is turned, while the other moves the first mentioned latch to release the piston rod, a hook on said 95 hinged shutter, a latch on the cabinet, and means connecting said latch and spring controlled rod consisting of a rack and pinion and arm, means for turning said pinion to operate the arm and rod and a spring con- 100 trolled lever connected with the pad holding door, and with the piston rod of the air valve, which is depressed, when the shutter is closed, and which raises the piston when the 105

shutter is released.

In testimony whereof we affix our signatures in presence of two witnesses.

JAMES F. WARE. THOMAS W. RUNDLE.
