A. G. KAUFMAN & L. J. LIPPMANN.

TELEPHONE RECEIVER.

APPLICATION FILED FEB. 7, 1907.

Patented Oct. 6, 1908.

UNITED STATES PATENT OFFICE.

ADOLPH G. KAUFMAN AND LEOPOLD J. LIPPMANN, OF NEW YORK, N. Y., ASSIGNORS TO AMERICAN CALLAPHONE COMPANY, OF NEW YORK, N. Y., A CORPORATION OF GEORGIA.

TELEPHONE-RECEIVER.

No. 900,387.

Specification of Letters Patent.

Patented Oct. 6, 1908.

Application filed February 7, 1907. Serial No. 356,171.

To all whom it may concern:

Be it known that we, ADOLPH G. KAUF-MAN and LEOPOLD J. LIPPMANN, both citizens of the United States, and residents of State of New York, have invented certain projecting portions being practically free. new and useful Improvements in Telephone- The magnet is preferably lamellated, as Receivers, of which the following is a specification.

Our invention relates to receivers for electric telephones and has for its object to construct a sensitive receiver which will produce sounds of great loudness and clearness, enabling the transmitted speech to be heard 15 at a considerable distance from the receiver, and also to insulate the receiver against the transmision of extraneous noises.

The invention will be fully described hereinafter, and the features of novelty pointed 20 out in the appended claims.

Reference is to be had to the accompany-

ing drawings, in which

Figure 1 is a sectional elevation of a telephone receiver embodying our invention; 25 Fig. 2 is a detail view of the receiver magnet and its connections, drawn upon an enlarged scale; Fig. 3 is a vertical section on line 3.3 of Fig. 1; Fig. 4 is a rear view showing another form of our invention; Fig. 5 illustrating only the magnets with their pole is mounted one end of an amplifying horn 30 shows still another form of our invention, pieces, spools and the socket which receives the diaphragm holder; and Figs. 6, 7, and 8 are detail views showing constructions of the 35 magnet pole pieces.

In the construction represented in Figs. 1, 2 and 3, A is a suitable casing which we prefer to secure elastically to the wall plate or other support B, as by means of springs C. 40 In order that dust may be excluded irrespective of any motion or vibration of the casing A, an expansible shield or curtain, such as the bellows D, may bridge the opening between the casing and its support B.

The front wall A' preferably forms a door which may be opened to give access to the magnet E and other parts within the casing. This magnet we generally arrange so that it will be comparatively free, that is practi-50 cally out of contact with the walls of the casing. For this purpose, a distance piece F (of wood or other suitable material) may be located between the front wall A' and the | K, and when the proper adjustment has been middle portion of the magnet E, while a obtained, the parts are secured against accross bar G is located against the rear sur- cidental displacement by means of a nut O, 110

face of the magnet, this crossbar, in conjunction with screws H, serving to fasten the magnet to the front wall or door A'. The magnet thus projects in opposite directions 5 the borough of Manhattan, city, county, and from its support or fastening, the ends or 60 shown, carrying pole pieces E1, by means of distance pieces E2 which may be non-magnetic, and screws E31 which in the present 65 case are of magnetic material. In any event, there should be a connection of magnetic material from the magnet to the pole pieces E1, but each pole piece should be magnetically separated from the other. The pole 70 pieces, which for securing the best results should have parallel slits as shown, carry the customary spools I of insulated wire with suitable connections to binding posts J, as shown best in Fig. 3. Preferably the 75 pole pieces and spools are located outside the casing A (the distance pieces E2 projecting through an opening in the front wall A') and are partly surrounded by the socket K secured in place by the screws E3. The 80. socket which is therefore carried by the magnet is screw threaded externally to receive the box L, provided with a clamping plate L' to hold the diaphragm M. To the clamping plate L'is secured centrally a tube L2 on which 85 N, capable of turning on said tube and held in position by means of a clamping ring N'. The amplifying horn may therefore be adjusted to different positions. We prefer to 80 employ the curved and gradually flaring construction shown, and we have discovered that this construction produces better results than a straight amplifying horn. The outer end of the horn is eccentric and one end is 95 parallel to the other, both being perpendicular to the plane of the diaphragm. It will be observed that the diaphragm box L with the diaphragm M and the horn N are carried directly by the magnet and will therefore 100 always remain in the same position relatively to the magnet, (even should the latter vibrate) unless the adjustment is changed by screwing the box L on its socket K. The distance between the diaphragm M 105 and the pole pieces of the magnet may be

varied by screwing the box L on the socket

which is preferably located outside the casing A so that the apparatus need not be opened or taken apart in order to effect the adjustment.

The peculiar way of supporting the magnet so that it is free in almost its entire length renders the device very sensitive and the magnet almost entirely independent of any vibrations of the casing A or its cover 10 A'. The elastic support or suspension of the casing safeguards it in a large measure against the transmission of vibrations to which the support or wall plate B may be

subjected.

In the construction illustrated by Figs. 1, 2 and 3, the magnet E is a simple horse-shoe magnet of the lamellated type. In Fig. 4 two such magnets E⁴ are employed with like poles adjacent to each other, and each pole piece E⁵ is magnetically connected with like poles of both magnets. The construction of the casing and the manner of securing the magnet, diaphragm, and amplifying horn thereto, may be the same as described with reference to Figs. 1, 2, and 3.

In Fig. 5 the two lamellated magnets E⁶ form a rectangular figure with centrally disposed and inwardly directed ends E⁷ from each of which a pole piece E⁸ projects at a right angle. The sections of these pole pieces are separated by slits as shown and may be made to form a curve with their outer edges, so that the magnetic action on the diaphragm will be more effective.

In Fig. 6, each pole piece is shown as of rectangular or angle-iron shape, with slits E° in one of its members. These slit pole pieces may be made to form a curve with the outer and inner edges, as shown in Fig. 8. In Fig. 7 individual pole pieces E° are employed, and secured together by a screw e. The other parts of this structure may be the same as before described, the spools I' being shaped to conform with the pole pieces E° in Figs. 5 and 8.

Most of the features disclosed herein are contained in an earlier application filed by us in the United States Patent Office, November 13, 1906, Serial No. 343,198.

We claim as our invention:

1. A telephone receiver, comprising a casing, a magnet support therein, a magnet carried by said support and projecting in opposite directions therefrom, pole pieces at the ends of the magnet, coils on said pole pieces, a diaphragm box carried by the magnet independently of the casing, and a diaphragm located in hid box adjacent, to the pole pieces.

2. A telephone receiver comprising a castoring, a magnet supported therein, magnet coils, a diaphragm box carried by the magnet directly and independently of the casing, and a diaphragm in said box.

3. A telephone receiver comprising a cas- 65 ing, a magnet supported therein, magnet coils, a diaphragm box carried by the magnet directly and independently of the casing and adjustable toward and from the magnet, and a diaphragm in said box.

4. A telephone receiver comprising a magnet the pole pieces of which having opposite polarity are located alongside of one another, each of said pole-pieces having a lateral off-set for connecting it to the magnet and being 75 provided with a plurality of slits and a

curved outer edge.

5. A telephone receiver comprising a casing, a magnet supported therein, magnet coils, a screwthreaded socket secured to the 80 magnet directly and supported independently of the casing, a diaphragm box having a screw connection with said socket, and a diaphragm in said box.

6. A telephone receiver comprising a cas- 85 ing, a magnet supported therein, a socket secured to the magnet directly and supported independently of the casing, pole pieces and magnet coils within said socket, a diaphragm box carried by said socket adjustably, and a 90

diaphragm in said box.

7. A telephone receiver comprising a casing, a magnet supported therein at a distance from its pole pieces so as to give the latter considerable freedom, a diaphragm 95 box carried directly by the pole piece portions of the magnet independently of the casing and movable relatively to the casing in unison with said magnet portions, and a diaphragm in said box.

8. A telephone receiver comprising a casing, a magnet supported therein at a distance from its pole pieces so as to give the latter considerable freedom, a diaphragm box carried adjustably by the pole piece portions of 105 the magnet independently of the casing and movable relatively to the casing in unison with said magnet portions, and a diaphragm in said box.

In testimony whereof, we have signed this 110 specification in the presence of two subscribing witnesses.

ADOLPH G. KAUFMAN. LEOPOLD J. LIPPMANN.
