APPLICATION FILED OCT. 22, 1902. 919,465. Patented Apr. 27, 1909. 2 SHEETS-SHEET 2. Witnesses: 3 a. G. Andean. Inventor:

UNITED STATES PATENT OFFICE.

FRANCIS H. RICHARDS, OF HARTFORD, CONNECTICUT, ASSIGNOR, BY MESNE ASSIGNMENTS, OF ONE-HALF TO AMERICAN TYPOGRAPHIC CORPORATION, A CORPORATION OF NEW JERSEY.

FLUID-CONTROLLED MECHANISM.

No. 919,465.

Specification of Letters Patent.

Patented April 27, 1909.

Application filed October 22, 1902. Serial No. 123,319.

To all whom it may concern:

a citizen of the United States, residing at Hartford, in the county of Hartford and 5 State of Connecticut, have invented certain new and useful Improvements in Fluid-Controlled Mechanisms, of which the following is

a specification.

This invention relates to apparatus, or 10 mechanism, in which it is desired to employ a confined volume of fluid for transmitting movements from an actuated device or mechanism to an actuatable device or mechanism, and has for its object to provide improved 15 mechanism whereby such results may be accomplished and the efficiency of the apparatus maintained.

The present invention is in part in the nature of an improvement on the invention 20 illustrated and described in Letters Patent of the United States No. 576,154, granted to me on Feb. 2, 1897, for hydraulic apparatus.

The present improvements relate more especially to means for supplying the appara-25 tus with a constant, and a constantly renewed, supply of fluid. The manner of accomplishing this result is such that the containers for the confined volume of fluid between the actuating and the actuated de-30 vices are supplied with fluid independently of the working of the body of fluid in the transmission of the desired movements. This result may be accomplished by introducing the fluid supply at a point inter-35 mediate said devices and in controlling the admission of fluid for supplying and also surcharging the container, be this what it may and connected spaces so as not to interfere with the operation of the fluid in the con-40 tamer.

In carrying out my invention means is provided whereby a confined body of fluid has pressure applied to it for actuating a device or mechanism.

The apparatus may be a key controlled one \{\) and each of the keys may be in operative connection with some suitable device, such as a plunger or piston capable of taking a predetermined quantity of fluid from a reservoir and forcing it into a container inclosing a body of fluid, which container may be connected with a piston or other suitable pressure-actuated device so constructed that upon the increase of pressure upon the body

of fluid incident to its increase in volume it 55 Be it known that I, Francis H. Richards, | will move the piston or device and impart movement to some portion of the apparatus, and if desired upon the movable part having completed a predetermined length or amount of movement the pressure may be relieved 60 upon the body of fluid, if desired, by conveying such fluid away from the container. The piston or other device may then be returned by any convenient means, and the bevice for adding the fluid to the body may also 65 be returned to its normal or initial position by some convenient means.

Upon each actuation the quantity of fluid, contained in the reservoir from which the measured fluid for the working impulse is 70 taken, may be diminished and such diminishing of the fluid may be compensated for by fluid from some suitable source of supply.

All the several finger-keys may be operative upon pistons drawing their supply of 75 fluid from the same reservoir, but each piston operative upon fluid contained in its individual container, which fluid will be operative upon its individual part of the apparatus. All the containers may be connected with a 80 single pump drawing from a suitable source of supply and forcing the fluid into a main line to which all the containers may be connected. The main line may also be connected with a storage device. The overflow 85 from all the parts may be connected with the supply for the pump.

In the drawings accompanying and forming part of this specification, Figure 1 is a diagrammatic view illustrating a form of 90 apparatus embodying my invention, some of the various parts being shown in vertical section, and Fig. 2 is a plan view thereof showing some of the parts in horizontal section and also arranged diagrammatically.

A designates in a general way a key-board wherein three keys 3 are shown, this number being employed in the present instance for the purpose of illustrating the invention, although it will be apparent that any num- 100 ber may be employed in practice. The keys are shown as provided with depending stems 4 passing through openings in a bar 5 secured to suitable framework 6. The key-stems are each shown as provided on the lower end 105 with a pin 7 engaging a slot in one arm 8 of a bell-crank-lever pivoted at 9 upon the framework and having a slot in the other arm 10

Mounted contiguous to the keys is a reservoir, designated in a general way by B and in the present instance shown as rising from the base of the same frame to which the side 5 members 6 are attached. Upon the opposite side of the reservoir from the bell-cranklevers are shown a series of cylinders 11 in each of which is mounted a piston 12 having a portion passing through or into the reser-10 voir and an end or stem 13 passing through the side wall thereof and provided with a pin engaging the slot in the lower end of one of the bell-crank-levers. It will be seen that the cylinders 11 open into the reservoir 15 B at a point below the top of this, which is to enable the piston to get a solid charge of fluid to force into the container, fluid which is not rendered elastic by presence of air bubbles which might be the case in certain 20 forms of the device. Suitable means, here shown as springs 14, may be employed for returning the bell-cranks and the keys to their normal positions.

The working end of the piston is shown as 25 comprising an open-ended hollow cylinder 15 having an entrance opening or port 16 capable of communicating with the interior of the reservoir. A suitable overflow may be provided for the reservoir, which in the present 30 instance is illustrated as comprising a dome or bell 17 rising from the cover 18 and having an overflow pipe 19 leading from the same, which is shown as emptying in a tray 20 provided upon the base of the framework.

The acturted device, represented in a general way by C, which in the present instance for the purpose of illustrating a practicable employment for my invention comprises an adding machine embracing a 40 stationary dial 21 and a movable indexfinger 22, the finger in the present instance being carried by a shaft 23 mounted in suitable bearings 24 rising from a base frame 25 and a number of ratchet-wheels 26 mounted 45 upon the shaft corresponding in number to the number of keys employed, to wit, in the present instance three.

Each ratchet-wheel is illustrated as having as many teeth as there are characters upon 50 the dial. Each ratchet-wheel is capable of being moved forward by means of a pawl 27 carried upon the end of a bell-crank-lever 28, and spring pressed if desired, by a suitable spring 29. The bell-crank-levers are shown 55 as mounted upon suitable bearings 29' rising | The conduit and cylinders constituting a 120 from the base of the frame. The bearings | fluid container and the increment of volume for the several bell-cranks are shown as of fluid in the container will actuate the pismounted in a line at an angle to the axis of the shaft and each one is provided with an upper arm of a length different from the length of the upper arms of the other bell cranks whereby the shaft will be moved forward a different distance upon the same amount of movement of the lower arm of the 65 bell-crank.

In the present instance the organization is supposed to represent that pressure on the key bearing the character one will move the shaft forward one tooth or step and the actuation of the key bearing the character 70 three will move the shaft forward three teeth or steps, thus indicating upon the dial, by the advance of the indicator, the number of points corresponding with the number borne by the finger-key which has been depressed. 75

For moving each bell-crank-lever a suitable piston-chamber, designated in a general way by D, may be employed, which in the present instance comprises a cylinder 30 connected with a suitable base, which in the 80 present instance is shown as the same base which carries the actuated device C. cylinder is shown as provided with a suitable piston 31 adapted to reciprocate in the cylinder, from which piston projects a stem 32 85 adapted to engage the lower end of its bellcrank and upon reciprocation in one direction to move the ratchet-wheel engaged by its pawl forward and upon the return to allow the pawl to ride over the ratchet-wheel 90 when it is being returned by some suitable device, in the present instance shown as a spring 33. The forward end 34 of the cylinder in the present instance is shown as closed and having an opening 34' forming a bearing 95 and support for the stem 32. Each end of the cylinder 30 is provided with a vent. The vent 35 in front of the piston is quite near the bearing for the stem, and the vent 36 behind the piston is located in such a position 100 that it will be uncovered by the piston when the same has reached the end of its working. stroke. The vents are at each side of the space occupied by the piston at the completion of its working stroke, the vent 35 is for 105 the purpose of admitting the free passage of air and for the overflow from any regitation, and the vent 36 for permitting the overflow of fluid from the cylinder to the end that the pressure upon the piston may be relieved and 110 it be returned to its normal position.

Conduits, designated in a general way by E, and in the present instance comprising tubes 37 may be employed to communicate the movement from the selector and its pis- 115 ton to the selected actuated device, and each conduit is shown as entering the ends of a cylinder from each of the respective series and as bent downward and then sidewise. ton controlling the actuated device. Each of the tubes 37 is provided with a service pipe 38. The several service pipes are shown as 125 connected with a main line 39. The main line in the present instance is shown as connected with a pump, designated in a general way by F, and may be of any suitable construction, which pump draws by means of a 130

919,465

suction pipe 40 from a source of supply, opening in the flange. To prevent lost modesignated in a general way by G, and forces tion and the smallest amount of loss of presthe fluid into the tubes 37, which tubes become filled from the piston-chambers 30 to 5 the point where they enter the reservoir B and will upon becoming filled also fill such of pressure to the fluid the ball will immedireservoir.

In some cases it will be desirable to employ | will be lost. a regulator or controlling device for insuring | In operation this apparatus, supposing it 10 the proper pressure of the fluid supply and is empty of fluid, first supplies fluid by the 75 also for accommodating the intermittent ad- action of the pump, or other supply mechanmission of fluid to the main line from a sup- ism, through a suitable main line and the ply mechanism operating continuously. This | check-valve, into the conduits or individual regulating device may consist of an accumu- lines at a point between the actuating and 15 lator of ordinary and of suitable proportions, and the surplus after filling the various parts of the apparatus may be conveyed along the main line to the accumulator, designated in a general way by H, which in the present in-20 stance comprises a cylinder 41 entered at its bottom portion by the main line and provided with a piston 42, here shown as of weighty construction and closely fitting the cylinder. A piston-rod 43 may be attached 25 to the piston and to any suitable counterweight (not shown) for forcing the fluid up the service pipes and into the tubes, provided the drain from the reservoir is greater than the normal action of the pump will sup-30 ply. Weights 44 may be placed upon the piston to regulate its pressure. A suitable overflow pipe 45 may run from the cylinder 41 to the supply tank G and a drain pipe 46 from a suitable tray 47 may connect there-35 with to carry off the overflow from the actuating pistons. A suitable overflow tube 48 may run from the tray 20, catching the surplus from the reservoir. The overflow pipes run into a portion 49 of the supply tank, 40 which in the present instance is shown as divided by a partition 50 solid at its lower portion and provided at its upper portion with a screen 51 whereby any dirt or foreign substance carried by the fluid may be permitted 45 to be thrown down or sink by gravity to the bottom and the upper part of the fluid be emptied in a clean condition into the side of the supply tank drawn from by the suction

pump. Each of the service pipes may be provided with suitable means for preventing the pressure of the actuation of one device being communicated to the entire system, which in the present instance are shown as ball-valves 52 55 comprising casings 53 each secured at its lower end upon the service pipe and at its upper portion connected thereto by a gland 55 and containing a ball 54 seating by gravity or pressure upon the bottom of the chamber, 60 which constitutes a valve seat 56. The valve is provided with a downwardly-projecting flange 57 having an opening 58, so that upon the rise of the ball from its seat it will engage such flange, but the passage of 65 fluid will not be checked thereby owing to the

sure the ball or other valve employed may be organized to be efficient upon a small amount of movement, whereby upon the application 70 ately seat itself and very little movement.

actuated mechanisms connected thereby. 80 The fluid passing into the conduits in this way naturally flows in both directions, thus expelling the air contained therein and finally reaching both mechanisms and flowing out. through all of the spaces and clearances un- 85 til the entire apparatus is fully supplied with fluid and the various pipes and spaces thereof are surcharged with the fluid. A particular advantage of this mode of supplying the apparatus is the rapid and effectual expulsion 90 of air from the connecting conduits and the interior spaces of the two apparatuses. For it will be remembered that notwithstanding the substantially inelastic character of ordinary fluids, such as water or oil, if a column 95 of considerable length of such fluid contains even a small percentage of air in the form of bubbles, the column, considered as a whole, thereby becomes elastic, and its efficiency is greatly depreciated when applied to the 100 transmission of mechanical movements from one apparatus to another.

In the apparatus described in my aforesaid prior Letters Patent the fluid for maintaining the supply in the conduit passes 105 through the ports or spaces formed in connection with the actuating piston; and while that method is found effective even in mechanisms of small dimensions (for which purpose the present improvements are more 110 especially intended) the present method has been found more effective for use under a wider range of conditions, especially when using oil.

Each of the actuated devices, in the pres- 115 ent instance, has its selector for actuating it, and upon the depression of a selector, illustrated as a finger-key, the piston connected thereto will force an amount of fluid from a reservoir B, common to several of such pis- 120 tons into a container for a confined volume of fluid, and here illustrated as the conduit E connecting the cylinder of such piston with the cylinder of the device selected for actuation. The former piston upon entering its 125 cylinder cuts off or valves the communication between the reservoir and the conduit: the further entry of the piston and the increased volume of fluid within the conduit causes the piston at the other end of the con- 130

duit or container to advance and actuate the selected member of the actuated mechanism. Upon the latter piston completing its working stroke it uncovers the vent, the in-5 crement of fluid is vented out or withdrawn from the conduit and the piston may then be returned to its initial position either by the return of the actuated device or otherwise. The reservoir is always in communication 10 with the supply and regulator through the non-active conduits, and is replenished and maintained constant from the regulating accumulator and the pump and the volume of fluid or the pressure in the conduits is 15 maintained normally constant or at not less than normal. The back-pressure valves may be constructed to have the minimum of movement in seating and rising so that there will be but small loss of pressure upon the ac-

20 tuation of the piston. Of course, many changes in detail may be had in practice without departure from the spirit of my invention. The number of actuated devices and selectors may be varied 25 as the requirements of each particular employment may demand. And the invention may be applied to an actuated device wherein several selectors may put into operation a number of actuated members simultane-30 ously, and the reservoir and conduits in such case will be replenished through the conduits not in use at that particular actuation, so that upon any of the individuals of one combination being repeated in the next successive com-35 bination the fluid in the reservoir will be efficient and the pump and regulator will have filled the conduits of such individuals instantly. The pressure and volume of fluid throughout the entire apparatus is main-40 tained constant, except during the brief instant of the increase in any conduit for actuation and the decrease due to venting the actuated cylinder.

Having described my invention, what I 45 claim and desire to secure by Letters Patent 1S---

1. The combination with a fluid container, of a movable device actuatable by a predetermined change of volume of fluid in the 50 container, a fluid reservoir, means for removing a volume of fluid equal to said predetermined volume from the reservoir and introducing the same into the container, means for replenishing the reservoir to the 55 normal volume of fluid, and means continuously in communication with the container means to the container.

2. The combination with a fluid container, 60 of a device capable of reverse movements connected therewith and actuatable in the respective directions by increment and decrement of fluid in the container, a fluid reservoir, means continuously in communi-

fluid into the container and from the container into the reservoir to maintain the volume of the fluid in each of these at not less than normal, and means for introducing fluid from the reservoir into and withdraw- 70 ing the same from the container to vary the volume therein and cause the respective movements of the said device.

3. The combination with a fluid container, of a movable device connected there- 75 with and movable upon change of pressure within the container, a fluid reservoir, means for introducing a portion of fluid from the reservoir into the container, and means continuously in communication with the con-80 tainer for maintaining the fluid within the container constant.

4. The combination with a series of fluid containers, of a plurality of devices connected therewith, severally capable of reverse 85 movements, and actuated by a change of fluid conditions in the connected container, a fluid reservoir connected to each of the containers; means for introducing fluid into the containers and maintaining the pressure 90 of the fluid at not less than normal, and for introducing fluid into the reservoir through the idle containers; means for stopping the flow of fluid from a selected container into the reservoir and for introducing fluid from 95 the reservoir into said selected container, and means to withdraw fluid from said selected container, for varying the pressure therein and causing the respective movements of the elements connected therewith. 100

5. In a device of the character specified, the combination with a series of movable devices; a series of pistons connected therewith and mounted in piston chambers; a series of actuators; a series of pistons mounted in pis- 105 ton chambers operated thereby; a series of conduits respectively connecting the piston chambers from each series; a fluid reservoir for supplying fluid to the pistons of the second named series, and through which said 110 pistons pass; a supply main; a service pipe connecting each of the conduits with the main, back pressure valves in each of the service pipes, the organization being such that fluid may be supplied to the conduits at 115 all times irrespective of the position of the parts, and that fluid will be supplied to the reservoir from the conduits, which for the time being are idle.

6. The combination with a plurality of 120 fluid containers, of a piston cylinder located for supplying fluid from the replenishing within each container; a piston mounted within each cylinder and actuated by a change of pressure within its container; a plurality of devices severally capable of a 125 number of movements and each controlled by one of the pistons; a fluid reservoir; means continuously open for the introduction of fluid into the containers to maintain 65 cation with the container for introducing | the pressure of the fluid therein and in the 130 919,465

reservoir at not less than normal; and means for introducing fluid from the reservoir into and withdrawing fluid from a selected container to vary the pressure therein and cause 5 the respective movements of the device connected therewith.

7. The combination with a plurality of fluid containers, of a piston cylinder connected with each container; a piston mounted with-10 in each cylinder and actuated by a change of volume of fluid within its connected container; a plurality of devices severally capable of a number of movements and each controlled by one of the pistons; a fluid reservoir; 15 continuously active means for supplying fluid; a connection and a back pressure valve means; and means for introducing fluid from the reservoir into and withdrawing the fluid 20 from a selected container to vary the volume of fluid therein and cause the respective movements of the devices connected there-

with. 8. In a device of the character specified, 25 the combination with mechanism embodying a series of work performing members, of a reservoir means for operating the members and each embodying a cylinder connected to the reservoir; a piston mounted therein; a 30 stem on the piston for engaging the member; means for guiding and supporting the piston stem; and a vent in the cylinder at each side of the space occupied by the piston at the completion of its working stroke; a fluid con-35 duit in communication with each cylinder; a fluid reservoir; means for constantly introducing fluid from the reservoir into the conduit operative upon a selected member to actuate the member; and means for replen-40 ishing the reservoir and maintaining the pressure within the conduits at not less than normal.

9. In a device of the character specified, the combination with a container; of a series 45 of movable members located therein; means for operating said members and embodying a series of cylinders; pistons mounted therein for actuating the members; and a vent in each of the cylinders behind the space occu-50 pied by the piston at the completion of its working stroke; selectors for the members; a reservoir for containing fluid; a series of piston cylinders connected with the reservoir; conduits each connecting a piston cylinder 55 from each series; pistons mounted in the piston cylinders opposite the reservoir and each controlled by a selector and embracing in a hollow open ended cylinder; and a port in the same adapted to make communication be-60 tween the interior of the reservoir and the conduit and establishing communication between the same, and upon movement into the cylinder to cut off and also introduce a predetermined amount of fluid from the res-

member to actuate the member, and means for replenishing the selector and maintaining the fluid in the conduit normally constant.

10. In a device of the character specified, the combination with a series of movable 70 members, of means for operating the members and embodying a series of cylinders, pistons mounted therein for actuating the members, and a vent in each of the cylinders behind the space occupied by the piston at 75 the completion of its working stroke; selectors for the members; a reservoir for containing fluid; a series of piston-cylinders connected with the reservoir; conduits each connecting a piston-cylinder from each series; pis- 80 tons mounted in the piston-cylinders of the between each container and said supplying | reservoir and each controlled by a selector and embracing an open-ended hollow cylinder, and a port in the same adapted to permit communication between the interior of 85 the reservoir and the conduit and establish communication between the same and upon movement into the cylinder to cut off and also introduce a predetermined amount of fluid from the reservoir into the conduit and op-90 erative upon the selected member to actuate the member; and means embodying a source of fluid supply, a pump drawing therefrom, connections between the pump and the conduits, an accumulator fed by the surplus de- 95 livery of the pump; and connections between the accumulator and conduits for replenishing the reservoir and maintaining the fluid in the conduits normally constant.

11. In a device of the character specified, 100 the combination with a series of movable members, of means operable by change of fluid for actuating the members; selectors for the members; a reservoir for containing fluid; a series of piston-cylinders connected with 105 the reservoir; conduits each connecting a piston-cylinder and an actuating means; pistons mounted in the piston-cylinders and each controlled by a selector and embracing an open-ended hollow cylinder; a port in the 110 same adapted to permit communication between the interior of the reservoir and the conduit and establish communication between the same and upon movement into the cylinder to cut off and also introduce a pre- 115 determined amount of fluid from the reservoir into the conduit and operative upon the selected member to actuate the member; and means for replenishing the reservoir through said conduits and maintaining the fluid in 120 the conduits normally constant.

12. In a device of the character specified, the combination with a series of movable members, of means operated by change of fluid for actuating the members; selectors 125 for the members; a reservoir for containing fluid; a series of piston-cylinders connected with the reservoir; conduits each connecting a piston-cylinder and an actuating means; 65 ervoir into the conduit and upon a selected | pistons mounted in the piston-cylinders and 130

each controlled by a selector and embracing an open-ended hollow cylinder; a port in the same adapted to permit communication between the interior of the reservoir and the 5 conduit and establish communication between the same and upon movement into the cylinder to cut off and also introduce a predetermined amount of fluid from the reservoir into the conduit and operative upon the 10 selected member to actuate the member; and means embodying a source of fluid supply, a pump drawing therefrom, connections between the pump and the conduits; an accumulator fed by the surplus delivery of the 15 pump; and connections between the accumulator and conduits for replenishing the reservoir and maintaining the fluid in the conduits normally constant.

13. The combination with a plurality of 20 fluid conduits, of a plurality of devices, severally capable of a number of movements, respectively connected therewith and each controlled by change of volume of fluid within its respective conduit; means for introduc-25 ing fluid from the reservoir into and withdrawing fluid from a selected conduit to vary the volume therein and cause the respective movements of the device connected therewith; and means for replenishing the reser-30 voir and maintaining the fluid in the conduits normally constant and embodying a source of fluid supply, a pump drawing therefrom, a main supplied by the pump and an accumulator fed by the surplus delivery of 35 the pump and comprising a cylinder in communication with the main, a pressure-piston therein and means for varying the pressure of

the piston.

14. In a device of the character specified, 40 the combination with a series of movable members, of means operable by change of volume of fluid for actuating the members; selectors for the members; a reservoir for containing fluid; a series of piston-cylinders 45 connected with the reservoir; conduits each connecting a piston-cylinder and an actuating means; pistons mounted in the pistoncylinders and each controlled by a selector and adapted to permit communication between the interior of the reservoir and the conduit and establish communication between the same and upon movement into the cylinder to cut off and also introduce a predetermined amount of fluid from the reser-55 voir into the conduit operative upon the selected member to actuate the member; and means for replenishing the reservoir and maintaining the fluid in the conduits normally constant and embodying a source of 60 fluid supply, a pump drawing therefrom, a main supplied by the pump and an accumulator fed by the surplus delivery of the pump and comprising a cylinder in communication with the main and a pressure-piston therein. 15. In a device of the character specified,

the combination with a series of movable members, of means operated by change of volume of fluid for actuating the members; selectors for the members; a reservoir for containing fluid; a series of piston-cylinders 70 connected with the reservoir; conduits each connecting a piston-cylinder and an actuating means; pistons mounted in the pistoncylinders and each controlled by a selector and adapted to permit communication be- 75 tween the interior of the reservoir and the conduit and establish communication between the same and upon movement into the cylinder to cut off and also introduce a predetermined amount of fluid from the reser- 80 voir into the conduit operative upon the selected member to actuate the member; and means for replenishing the reservoir and maintaining the fluid in the conduits normally constant and embodying a source of 85 fluid supply, a pump drawing therefrom, a main supplied by the pump and an accumulator fed by the surplus delivery of the pump and comprising a cylinder in communication with the main, a pressure-piston therein and 90 means for varying the pressure of the piston.

16. In a device of the character specified, the combination with a series of movable members, of means operated by change of volume of fluid for actuating the members; 95 selectors for the members; a reservoir for containing fluid; a series of piston-cylinders connected with the reservoir; conduits each connecting a piston-cylinder and an actuating means; pistons mounted in the piston- 100 cylinders and each controlled by a selector and adapted to permit communication between the interior of the reservoir and the conduit and establish communication between the same and upon movement into the 105 cylinder to cut off and also introduce a predetermined amount of fluid from the reservoir into the conduit operative upon the selected member to actuate the member; and means for replenishing the reservoir and 110 maintaining the fluid in the conduits normally constant and embodying a source of fluid supply, a pump drawing therefrom, a main supplied by the pump, a cylinder in communication with the main, a weighted 115 piston within the cylinder and means for adjustably varying the weight thereof.

17. In a device of the character specified, the combination with a series of movable members, of means operated by change of 120 volume of fluid for actuating the members; selectors for the members; a reservoir for containing fluid; a series of piston-cylinders connected with the reservoir; conduits each connecting a piston-cylinder and an actuat- 125 ing means; pistons mounted in the pistoncylinders and each controlled by a selector and adapted to permit communication between the interior of the reservoir and the conduit and establish communication be- 130

919,465

tween the same and upon movement into the! cylinder to cut off and also introduce a predetermined amount of fluid from the reservoir into the conduit operative upon the se-5 lected member to actuate the member; and means for replenishing the reservoir and maintaining the fluid in the conduits normally constant and embodying a source of fluid supply, a pump drawing therefrom; a 10 main supplied by the pump, an upright cylinder in communication with the main, a piston within the cylinder and weights for adjustably varying the pressure thereof.

18. In a device of the character specified, 15 the combination with a series of movable members, of means operated by change of volume of fluid for actuating the members; selectors for the members; a reservoir for containing fluid; a series of piston-cylinders 20 connected with the reservoir; conduits each connecting a piston-cylinder and an actuating means; pistons mounted in the pistoncylinders and each controlled by a selector and adapted to permit communication be-25 tween the interior of the reservoir and the conduit and establish communication between the same and upon movement into the cylinder to cut off and also introduce a predetermined amount of fluid from the 30 reservoir into the conduit operative upon the selected member to actuate the member; and means for replenishing the reservoir and maintaining the fluid in the conduits normally constant and embodying a source of fluid supply, a pump drawing therefrom, a overflow connected with the reservoir; means main supplied by the pump, a cylinder in for catching the overflow; and means for communication with the main, a weighted piston within the cylinder and means for adjustably varying the weight thereof.

19. The combination with a fluid-container, of a movable device connected therewith and operable upon change of volume of fluid within the container; a fluid reservoir; means for introducing a portion of fluid from 45 the reservoir into the container; and means for replenishing the reservoir and for maintaining a volume of fluid within the container not less than the normal volume and embodying a source of fluid supply, a pump 50 drawing therefrom, a main supplied by the pump, an upright cylinder in communication with the main, a piston within the cylinder and weights for adjustably varying the pressure thereof.

55 20. In a device of the character specified, the combination with mechanism embodying a series of work-performing members; means for yieldably holding the members in their idle positions, means for operating the 60 members and each embodying a cylinder; a piston mounted therein; a stem on the piston for engaging the member; and means for guiding and supporting the piston-stem and comprising a closed end of the cylinder 65 provided with an opening; a vent in front

of the piston; a vent behind the piston; a reservoir for containing fluid; a series of piston cylinders connected with the reservoir; tubes each connecting a piston cylinder from each series; pistons mounted in the 70. piston cylinders of the reservoir and each embracing an open-ended hollow cylinder; a port in the same adapted to communicate with the interior of the reservoir and establish communication between the same and 75 the cylinder and upon movement into the cylinder to cut off; a stem on each piston passing through the wall of the reservoir; a series of depressible finger-keys; a stem depending from each key; a bell-crank-lever 80 connected with the stem of each key and with the stem of one of the pistons; means for retracting the pistons; a fluid-supply tank; a pump for drawing fluid therefrom; a supply main connected to the pump; a 85 service pipe connected to the main for each tube; a back-pressure valve in each sérvice pipe; an accumulator connected with the main and embodying a cylinder; a piston therein; weights for regulating the pressure 90 of the piston; a receiving compartment in the supply tank embodying a partition closed at its lower portion and provided at its upper portion with a screen communicating with the-body of the tank; an overflow pipe from 95 the accumulator to the receiving compartment; an overflow pan for receiving the fluid from the actuated pistons; a conduit therefrom to the receiving compartment; a valve overflow connected with the reservoir; means 100 conveying the same to the receiving compartment.

21. In a device of the character specified, the combination with a shaft, of ratchet- 105 wheels mounted thereon; a series of bellcrank-levers mounted adjacent thereto and all having one arm of uniform length and the other arm of dissimilar length; a pawl carried by each of the dissimilar arms for engag- 110 ing the ratchet-wheel; yieldable means for holding the bell-cranks in their initial posttions; means for operating the several bellcranks and each embodying a cylinder; a piston mounted therein; a stem on the pis- 115 ton for engaging the bell-crank; and means for guiding and supporting the piston-stem and comprising a closed end of the cylinder provided with an opening; a vent in front of the piston; a vent behind the piston; a reser- 120 voir for containing fluid; a series of piston cylinders connected with the reservoir; tubes each connecting a piston cylinder from each series; pistons mounted in the piston cylinders of the reservoir and each embracing 125 an open-ended hollow cylinder; a port in the same adapted to communicate with the interior of the reservoir and establish communication between the same and the cylinder and upon movement into the cylinder to cut 13

off; a stem on each piston passing through the wall of the reservoir; a series of depressible finger-keys; a stem depending from each key; a bell-crank-lever connected with the 5 stem of each key and with the stem of one of the pistons; means for retracting the pistons; a fluid-supply tank; a pump for drawing fluid therefrom; a supply main connected to the pump; a service pipe connected to the main 10 for each tube; a back-pressure valve in each service pipe; an accumulator connected with the main and embodying a cylinder; a piston therein; weights for regulating the 15 ment in the supply tank embodying a partition closed at its lower portion and provided at its upper portion with a screen communicating with the body of the tank; an overflow pipe from the accumulator to the re-20 ceiving compartment; an overflow pan for receiving the fluid from the actuated pistons; a conduit therefrom to the receiving compartment; a valve overflow connected with the reservoir; means for catching the over-25 flow; and means for conveying the same to

the receiving compartment. 22. The combination with a plurality of fluid-containers, of a piston-cylinder connected with each container a piston mounted 30 within each cylinder and actuated by change of pressure within its container, a vent to relieve the pressure upon each piston at the completion of its stroke, a plurality of devices capable of a number of movements and 35 each controlled by one of the pistons, a fluid reservoir, means for introducing fluid into the containers to maintain the pressure of the fluid at not less than normal and from the idle containers into the reservoir, and means 40 for introducing fluid from the reservoir into and venting fluid from a selected container to vary the pressure therein and cause the respective movements of the device connected therewith.

23. The combination with a plurality of fluid-containers, of a piston-cylinder connected with each container, a piston mounted within each cylinder and actuated by change of volume of fluid within its con-50 tainer, a vent to relieve the pressure upon each piston at the completion of its stroke, a plurality of devices severally capable of a number of movements and each controlled by one of the pistons, a fluid reservoir, means 55 for introducing fluid into the containers to maintain the volume of fluid at not less than normal and from the idle containers into the reservoir, and means for introducing fluid from the reservoir into and venting fluid 60 from a selected container to vary the volume of fluid therein and cause the respective movements of the device connected there-

with. 24. The combination with a plurality of 65 fluid-containers, a piston-cylinder connected

with each container, a piston mounted within each cylinder and actuated by change of pressure within its container, a vent behind each piston, a plurality of devices severally capable of a number of movements and each 70 controlled by one of the pistons, a fluid reservoir, means for introducing fluid into the containers to maintain the pressure of the fluid at not less than normal and from the idle containers into the reservoir, and means 75 for introducing fluid from the reservoir into and discharging fluid from a selected container to vary the pressure therein and cause pressure of the piston; a receiving compart- | the respective movements of the device connected therewith.

25. The combination with a plurality of fluid-containers, of a piston-cylinder connected with each container, a piston mounted within each cylinder and actuated by change of volume of fluid within its container, a vent 85 behind each piston, a plurality of devices severally capable of a number of movements and each controlled by one of the pistons, a fluid reservoir, means for introducing fluid into the containers to maintain the volume of 90 fluid at not less than normal and from the idle containers into the reservoir, and means for introducing fluid from the reservoir into and discharging fluid from a selected container to vary the volume of fluid therein and 95 cause the respective movements of the device connected therewith.

26. The combination with a plurality of fluid-containers, of a piston-cylinder connected with each container, a piston mounted 100 within each cylinder and actuated by change of pressure within its container, a vent from the cylinder at each side of the space occupied by the piston at the completion of its working stroke, a plurality of devices sever- 105 ally capable of a number of movements and each controlled by one of the pistons, a fluid reservoir, means for introducing fluid into the containers to maintain the pressure of the fluid at not less than normal and from the 110 idle containers into the reservoir, and means for introducing fluid from the reservoir into and venting fluid from a selected container to vary the pressure therein and cause the respective movements of the device con- 115 nected therewith.

27. The combination with a plurality of fluid-containers, of a piston-cylinder connected with each container, a piston mounted within each cylinder and actuated by change 120 of volume of fluid within its container, a vent from the cylinder at each side of the space occupied by the piston at the completion of its working stroke, a plurality of devices severally capable of a number of movements and 125 each controlled by one of the pistons, a fluid reservoir, means for introducing fluid into the containers to maintain the volume of fluid at not less than normal and from the idle containers into the reservoir, and means 130

for introducing fluid from the reservoir into and venting fluid from a selected container to vary the volume of fluid therein and cause the respective movements of the device con-5 nected therewith.

28. The combination with a plurality of fluid containers, of a piston cylinder connected with each container; a piston mounted within each cylinder and actuated by change 10 of pressure within its tube; a plurality of devices severally capable of a number of movements and each controlled by one of the pistons; a fluid reservoir; means for introducing fluid into the tubes to maintain the 15 pressure of the fluid at not less than normal and from the idle containers into the reservoir; means for introducing fluid from the reservoir into a selected tube to vary the pressure therein and cause a movement of 20 the device connected therewith; and a vent from the cylinder behind the space occupied by the piston at the completion of its working stroke for permitting another movement of the device.

29. The combination with a plurality of fluid containers, of a piston-cylinder connected with each container, a piston mounted within each cylinder and actuated by change of volume of fluid within its container, a plu-30 rality of devices severally capable of a number of movements and each controlled by one of the pistons, a fluid reservoir, means for introducing fluid into the containers to maintain the volume of fluid at not less than 35 normal and from the idle containers into the reservoir. means for introducing fluid from the reservoir into a selected container to vary the volume of fluid therein and cause a movement of the device connected therewith, and 40 a vent from the cylinder behind the space occupied by the piston at the completion of its working stroke for permitting the escape of fluid and another movement of the device.

30. The combination with a series of fluid45 containers, of a series of movable devices severally connected therewith and movable upon change of pressure within the respective containers, a fluid reservoir, means for introducing a portion of fluid from the reser50 voir into each container, and means for maintaining the fluid within the reservoir constant from the idle containers.

31. The combination with a fluid-container, of a movable device connected there55 with and operable upon change of pressure within the container, a fluid reservoir, a piston-chamber in communication with the container and with the reservoir below the upper portion thereof, and a piston mounted in the chamber and comprising an open-ended hollow cylinder and a port for opening and closing communication between the reservoir and container, the open end of said cylinder being directed toward the container.

32. In a device of the character specified.

the combination with a plurality of fluid-containers, mechanism connected with each of these and operable upon change of volume of fluid within the container, a piston-chamber connected with each container, a fluid resertion voir in communication with all of the piston-chambers, a piston provided with a hollow end working in each of the piston-chambers and provided with an inlet-port through which the reservoir and chamber may be put 75 in inter-communication, a stem depending from each of the keys, and a bell-crank-lever engaged by each of the key-stems and engaging the respective piston-stems.

33. The combination with a fluid-con- 80 tainer, of a movable device connected therewith and movable upon change of pressure within the container, means for introducing fluid into the container to maintain the pressure of the fluid at not less than normal, 85 means for introducing fluid into the container to raise the pressure therein and move the device, and means for back-valving the normal pressure maintaining means during the increment of pressure.

34. The combination with a fluid-container, of devices capable of a plurality of movements, connected therewith and controlled by change of pressure within the container, means for introducing fluid into the 95 container to maintain the pressure of the fluid at not less than normal, and means for introducing fluid into and withdrawing fluid from the container to vary the pressure therein and cause the respective movements of the 100 device, and means for back-valving the normal pressure maintaining means during the increment of pressure.

35. The combination with a fluid-container, of devices capable of a plurality of 105 movements in the container, connected therewith and controlled by change of volume of fluid within the container, means for introducing fluid into the container to maintain the volume of the fluid at not less than 110 normal, and means for introducing fluid into and withdrawing fluid from the container to vary the volume therein and cause the respective movements of the device, and means for back-valving the normal pressure maintaining means during the increment of pressure.

36. The combination with a plurality of fluid-containers, of a plurality of devices severally capable of a number of movements, 120 respectively connected therewith and each controlled by change of pressure within its respective container, means for introducing fluid into the containers to maintain the pressure of the fluid at not less than normal, and 125 means for introducing fluid into and withdrawing fluid from a selected container to vary the pressure therein and cause the respective movements of the device connected therewith, and means for back-valving the 130

the increment of pressure.

37. The combination with a plurality of fluid-containers, of a plurality of devices sev-5 erally capable of a number of movements, respectively connected therewith and each controlled by change of volume of fluid within its respective container, means for introducing fluid into the containers to maintain 10 the volume of the fluid at not less than normal, means for back-valving the normal pressure maintaining means during the increment of pressure, and means for introducing fluid into and withdrawing fluid from a se-15 lected container to vary the volume therein and cause the respective movements of the device connected therewith.

38. In a device of the character specified, the combination with a shaft, of ratchet-20 wheels mounted thereon, a series of bellcrank-levers mounted adjacent thereto and all having one arm of uniform length and the other arm of dissimilar length, a pawl carried by each of the dissimilar arms for engaging 25 the ratchet-wheel, yieldable means for holding the bell-cranks in their initial positions, and fluid-actuated means for operating the

respective bell-cranks.

39. In a device of the character specified, 30 the combination with a shaft, of ratchetwheels mounted thereon, a series of levers mounted adjacent thereto and all having one arm of uniform length and the other arm of dissimilar length, pawls carried by the dis-35 similar arms for engaging the ratchet-wheels,

normal pressure maintaining means during | yieldable means for holding the levers in their initial positions, and fluid-actuated means for operating the respective levers and engageable with the arms of uniform length, a plurality of ratchet-wheels, a series of levers 40 mounted adjacent thereto and all having one arm of uniform length and the other arm of dissimilar length, means of connection between the several arms of uniform length and the respective pistons, pawls carried by the 45 arms of dissimilar length, for engaging the ratchet-wheels, and means for maintaining the levers at initial position.

40. The combination with a plurality of fluid containers, of a piston cylinder connect- 50 ed with each container, a piston mounted within each cylinder and actuated by change of volume of fluid within its connected container, a plurality of ratchet-wheels, a series of levers mounted adjacent thereto and all 55 having one arm of uniform length and the other arm of dissimilar length, means of connection between the several arms of uniform length and the respective pistons, pawls carried by the arms of dissimilar length, for en- 60 gaging the ratchet-wheels, and means for maintaining the levers at initial position.

In testimony whereof, I have hereunto signed my name at Nos. 9-15 Murray street, New York, N. Y., this 21st day of October, 65

1902.

FRANCIS H. RICHARDS.
