## UNITED STATES PATENT OFFICE.

JESSE LAURANCE DENSON, OF ST. LOUIS, MISSOURI.

## ANTI-RAIL-SPREADER

No. 930,941.

Specification of Letters Patent.

Patented Aug. 10, 1909.

Application filed December 16, 1908. Serial No. 467,833.

To all whom it may concern:

Be it known that I, JESSE LAURANCE DENson, a citizen of the United States, residing at St. Louis, State of Missouri, have invented new and useful Improvements in Anti-Rail-Spreaders, of which the following is a specification.

This invention is an improved anti rail spreader for use on railroads to prevent the 10 rails from spreading and which consists in a tie composed of a pair of members having means at their outer ends to engage the rails and having wedge shoulders at their inner ends, in combination with a tie device hav-15 ing wedge shoulders at its sides to engage those of the said sections to lock said sections together and draw them toward each other and further provided with a lip or stop at its larger end to be turned down when 20 said tie is in place and bear against one side of said sections to prevent casual disengagement of said tie as hereinafter described and claimed.

In the accompanying drawings:—Figure 1 25 is a top plan of a portion of a railway provided with anti rail spreaders constructed in accordance with my invention. Fig. 2 is a transverse sectional view on a larger scale. Fig. 3 is a detail perspective view of one of 30 the anti rail spreaders showing the parts

thereof disconnected. My improved anti rail spreader comprises a pair of bars or sections 1, 2, which are duplicates of each other and each of which is 35 provided at its outer end with a broadened head portion 3 and at its inner end with a wedge shoulder or flange 4, said wedge shoulders or flanges being here shown as formed by turning up and bending over the inner end 40 portions of said sections or bars. Each head portion 3 is formed with an upturned flange 5 to bear against the outer side of one of the rails and is further formed with lip portions 6 which after the outer flanges 5 are applied 45 to the rails are bent over the inner base

flanges of the rails and against the inner sides of the webs thereof, as indicated in Fig. 2, it being observed that the head portions 3 are wider than the bars and that the said 50 lips 6 as well as the flanges 5 are formed integral with said head portions.

In order to lock the sections or bars 1, 2, together, end for end, I provide a wedge

side with inwardly extending flanges 8 to en- 55 gage and underlie the wedge flanges 4 of the bars or sections 1, 2, the sides of the said clip converging in one direction so that the said clip also constitutes a wedge which in coaction with the wedge flanges 4 of the bars or 60 sections 1, 2, serves to firmly lock said bars or sections 1, 2 together and to draw them toward each other when the clip is forced or driven into place. The clip is provided at its larger end and integrally with its upper 65 portion with a lip 9 which when the clip has been thus placed on the meeting ends of the bars 1, 2, is bent downward so as to bear against one side of said bars as indicated in Fig. 1, said lip thus serving to effectually 70 prevent the said clip from becoming casually dislodged. It will be understood, however, that by first bending up the said lip 9 the said wedge clip may be readily removed from the said bars or sections 1, 2, to permit of 75 their disengagement from the rails.

It will be understood from the foregoing that my improved anti rail spreader may be readily attached to the rails of a railroad track and that it is effective to prevent the 80 spreading of the rails.

I do not desire to limit myself to the precise construction and combination of devices herein shown and described, as modifications may be made therein within the scope 85 of the appended claims

What is claimed is:-

1.—An anti rail spreader comprising a pair of bars having means at their outer ends to engage the rails and provided at their inner 90 ends with wedge flanges, in combination with a wedge clip to coact with said wedge flanges and lock said bars together at their inner ends.

2. An anti rail spreader comprising a pair 95 of bars having means at their outer ends to engage the rails and provided at their inner ends with wedge flanges, in combination with a wedge clip to coact with said wedge flanges and lock said bars together at their inner 100 ends, said wedge clip being provided with locking means to engage said bars and prevent casual dislodgment of said wedge clip.

3. An anti rail spreader comprising a pair of bars formed at their inner ends with wedge 105 flanges and at their outer ends with broadened head portions, said head portions havshaped clip 7 which is formed on its under ling their outer ends upwardly and inwardly

turned to form flanges to bear against the outer sides of the rails and formed on their inner sides with lip flanges to be bent against the inner sides of the rails, in combination with a wedge clip to engage and coact with the wedge flanges of said bars to lock the latter together.

In testimony whereof I affix my signature in presence of two witnesses.

JESSE LAURANCE DENSON.
