## UNITED STATES PATENT OFFICE.

EDMUND A. SCHADE, OF NEW BRITAIN, CONNECTICUT, ASSIGNOR TO THE STANLEY RULE & LEVEL COMPANY, OF NEW BRITAIN, CONNECTICUT, A CORPORATION OF CONNECTICUT.

PLANE.

987,081.

Specification of Letters Patent.

Patented Mar. 14, 1911.

Application filed December 27, 1910. Serial No. 599,481.

To all whom it may concern:

Be it known that I, EDMUND A. SCHADE, a citizen of the United States, residing at New Britain, county of Hartford, State of Con-5 necticut, have invented certain new and useful Improvements in Planes, of which the following is a full, clear, and exact description.

My invention relates to an improved frog 10 adjustment for a bench plane, whereby the frog, which is the means for supporting the plane iron, may be readily adjusted to and fro, and which, when locked in position, is rigidly held in such a manner as to reduce 15 to a minimum any chance of slippage or displacement.

In the drawings, Figure 1 is a longitudinal section of a plane showing my improved adjustment. Fig. 2 is a section on the plane 20 of the line x-x, Fig. 1, looking from left to right. Figs. 3, 4 and 5 are detail views. Fig. 6 is a longitudinal section of part of a plane of slightly modified construction from that shown in Fig. 1, my invention being <sup>25</sup> applied thereto. Fig. 7 is a cross section on the line y-y of Fig. 6, looking from right to left. Fig. 8 is a longitudinal section of a part of a plane of another modified form. Fig. 9 is a cross section on the 30 line z—z Fig. 8, looking from left to right. Fig. 10 is a longitudinal section illustrating still another modification. Fig. 11 is a cross section thereof on the line w-w looking from right to left.

Referring to Figs. 1 to 5, 1 represents a sole of an iron bench-plane which may be, as to general details, of conventional form. 2 is a frog bearing, in this particular instance formed on an incline directly to the 40 rear of the throat 3. 4 is a frog adjustably mounted on the support 2 for movement to and fro relatively to the throat 3. 5 is a plane iron. 6 is a cap of conventional form and by which the plane iron may be clamped 45 to the frog 4. The invention in this case resides primarily in the means for adjustably securing the frog 4 to the frog support 2. In this instance the frog is provided with two longitudinal slots or passages 50 7 in which stand clamping or gripping studs 1

8—8. These studs are headed, the headed portions standing above the slots, the opposite ends projecting down into cavities or recesses in the support 2. Each stud is transversely recessed toward its lower end, 55 as indicated at 9. 10 is what I will term a cam stud, there being one for each gripping stud 8. The cam studs are arranged in the support 2, suitable bores being provided therefor, the rear ends of said studs being 60 arranged to receive a suitable tool, for example, a screw driver, the forward end of each cam stud being provided with an eccentric projection or cam 11. This cam 11 projects into the recess 9 of the respective grip- 65 ping stud. 12 is a slot in the side of each cam stud. Entering from the side of the plane is a locking screw 14, the same being so arranged relatively to the slotted portion 11 of the cam stud that the forward ends 70 of each screw 14 will engage the wall at the base of the recess 12 at one side of, or eccentric to, the axis of the cam stud.

In the operation of the parts thus far described, it will be seen that by rotating the 75 cam stud in the proper direction, the cam 11 will engage with the wall at the lower end of the recess 9 in the gripping stud so that said gripping stud will be pulled down into firm gripping engagement with the frog 80 4. To give a further set to the cam and to guarantee against disengagement, the screw 14 may be turned in until its nose engages eccentrically said cam stud, tending to turn it in a direction to increase the tension of 85 the cam on the gripping stud and also preventing any rotation of the cam stud in a reverse direction to release said gripping stud. I have found, by this means, that the frog may be very quickly and easily ad- 90 justed, and, at the same time, when locked in position, is held with exceeding rigidity.

In the other views I have shown slight modifications. For example, in Figs. 6 and 7 I have shown the frog 4a as mounted upon 95 a support 2<sup>a</sup> having a two-point bearing for the frog. In this case as before, the frog is held by means of gripping studs 8a operated by cam studs 10° which are in turn controlled by screws 14<sup>a</sup>.

100

In Figs. 8 and 9 I have shown a modification in which instead of providing the gripping studs 8 for holding the frog to its seat, I have provided the frog 4b with a 5 plate-like extension 8b which is preferably cast into the frog, so as to be a permanent part thereof, said plate 8b having passages to receive the cam ends 11b of the cam studs 10b. In this case, as previously, the side 10 screws 14<sup>b</sup> may be employed to coöperate with the cam studs for the same purpose as before.

In Figs. 10 and 11 I have shown a modification more particularly of the construc-15 tion shown in Fig. 8 in that instead of anchoring the aforesaid plate in the frog, I have anchored a similar plate in the frog support. In these views, 8° represents said plate anchored in the support 2°, and in 20 this case the cam studs 10° are carried in passages in the rear of the frog 4°, the cam ends 11° engaging the walls of the slot in the plate 8° in the same manner as the cam ends 11<sup>b</sup> engage the walls of the slot in the 25 plate 8b, shown in Figs. 8 and 9. Here again take-up screws are employed, the same being indicated at 14°. In this case the takeup screws are carried by threaded bores in the sides of the frog, suitable windows or 30 clearance openings 15 being provided in the cheek pieces of the plane to permit a screw driver to be entered sufficiently to engage the slotted ends of said screws 14° for the purpose of operating the same.

In both forms of devices shown in Figs. 8 to 11, a suitable clearance space is provided for the plates 8b and 8c respectively whereby there may be a relative movement between said plate and the part carrying 40 the cam screw. In these cases, the cam ends 11<sup>b</sup> and 11<sup>c</sup> respectively should be of sufficient length to engage the plates 8<sup>b</sup> and 8° respectively in all of the various posi-

tions of adjustment. What I claim is:

1. In a plane, a main body portion having a throat therein, a frog support at the rear of said throat, a frog adjustable to and fro thereon, a locking means for holding 50 said frog in different positions of adjustment comprising a clamping member operatively engaged with one of said parts, means for operating said clamping member carried by the other part and comprising a 55 rearwardly projecting cam stud coacting with said clamping member, and a lock and tightener for said cam stud, said lock and tightener comprising a laterally projecting exposed screw engaging said cam stud in a 60 direction to turn the same as said lock and tightener is advanced.

2. In a plane, a main body portion having

a throat therein, a frog support at the rear of said throat, a frog adjustable to and fro thereon, a locking means for holding said 65 frog in different positions of adjustment comprising a clamping member operatively engaged with one of said parts, means for operating said clamping member carried by the other part and comprising a rearwardly 70 projecting cam stud coacting with said clamping member, a lock for said cam stud, said lock comprising a laterally projecting exposed screw, and a shoulder on one side of said cam stud eccentric thereto, said 75 screw engaging said eccentric shoulder and pressing against the same in a direction to turn said cam stud so as to more tightly engage the clamping member.

3. In a plane, a body portion having a 80 throat, a frog support at the rear of said throat, a frog adjustable to and fro on said support and relatively to said throat, a clamping member carried by said frog and projecting into said support, said support 85 having a recess therefor, a cam stud carried in said support and exposed at its rear end, an eccentric pin extension at the forward end of said stud eccentrically engaging said clamping member, and a lock screw 90 for engaging said clamping stud at one side

and arranged laterally thereto.

4. In a plane, a body portion having a throat, a frog support at the rear of the throat, a frog mounted for adjustment to 95 and fro on said support, said frog having a fore and aft slot therein, a clamping stud passing downwardly through said slot into said support, an operating device for said clamping stud comprising a cam stud 100 mounted in said support, an eccentric pin projection at the forward end of said cam stud eccentrically engaged with said clamping stud, and a lock for said cam stud.

5. In a plane, a body portion having a 105 throat, a frog support at the rear of the throat, a frog mounted for adjustment to and fro on said support, said frog having a fore and aft slot therein, a clamping stud passing downwardly through said slot into 110 said support, an operating device for said clamping stud comprising a cam stud mounted in said support, an eccentric pin projection at the forward end of said cam stud eccentrically engaged with said 115 clamping stud, and a lock for said cam stud, said lock comprising a screw entering said frog support from the side of the plane.

6. In a plane, a body portion having a 120 throat, a frog support at the rear of the throat, a frog mounted for adjustment to and fro on said support, said frog having a fore and aft slot therein, a clamping stud

passing downwardly through said slot into said support, an operating device for said clamping stud comprising a cam stud mounted in said support and eccentrically engaged with said clamping stud, and a lock for said cam stud, said lock comprising a screw entering said frog support from the side of the plane, said screw engaging said

cam stud eccentrically to rotate the same in a direction to increase the pressure on the 10 clamping stud.
