THE NORRIS PETERS CO., WASHINGTON, D. C.

UNITED STATES PATENT OFFICE.

HERBERT G. SMITH, OF BARTLESVILLE, OKLAHOMA.

PUMPING-JACK.

992,075.

Specification of Letters Patent.

Patented May 9, 1911.

Application filed June 12, 1908. Serial No. 438,250.

To all whom it may concern:

tlesville, in the county of Washington and 5 State of Oklahoma, have invented certain new and useful Improvements in Pumping-Jacks, of which the following is a specification, reference being had therein to the accompanying drawing.

My invention relates to machine elements, and especially to pumping jacks and the

like.

It has for its object the provision of means whereby motion may be communicated from 15 a rocking member to a reciprocating member without disturbing the alinement of the latter and without the use of rotating bearings.

I shall describe the invention as embodied 20 in a pumping jack, but of course this is to be taken as definitive and not restrictive, since numerous other applications of the

same principle may be made.

The type of pumping jack now generally 25 in use is that having a rigid frame carrying | is a face view thereof. Fig. 4 is a side view a bell crank lever or rocker journaled in the frame at its angle with one arm dropping downward and connected with the pull rod, while the other extends horizontally forward 30 and is connected with the polished rod or sucker rod of the pump. This rod passes through a cross-head, above which is a clamp fastened to the rod. At the ends of this cross-head are side arms, these lying 35 parallel and serving as links to connect the lower cross-head with a fixed cross-head above. They are secured in place by means of nuts. This forms a swinging joint, and since it affords no support for the polished 40 rod, the latter is held in plumb by means of an arc-shaped guide carried by the rocking lever and having its center in the axis of the lever. With this arrangement there is constant wear on all the bearings, and it is 45 difficult to gear up and ungear, on account of the many parts requiring tools in their adjustment.

According to my present improvement, I still make use of the rigid frame and the 50 rocker lever connected through its lower arm to a pull rod and through its upper arm to the polished rod. Instead of circular bearings for the side arms or links, however, I provide what I may term rocker bearings 55 in which there is little or no friction, the movement depending on two surfaces com-

ing together as cams without lateral dis-Be it known that I, Herbert G. Smith, a placement. The arc-shaped guide may be citizen of the United States, residing at Bar- employed or may be omitted, the complete improvement contemplating its omission.

> My present construction may be briefly described as a swinging joint composed of a pair of double-ended stirrups hung over rocking cams. By properly shaping the curved faces of these cams, the arc-shaped 65 guide may be done away with. Since the bearing points for the swinging joint constantly change at both ends during their movement, it is only necessary to adjust the parts so that the mean amplitude of change 70 will equal the lateral displacement due to the arc of stroke, to keep the pull always perpendicular and the rod properly alined.

My invention is illustrated in the accom-

panying drawings wherein— . Figure 1 shows a pumping jack of the type mentioned, with my improvement applied thereto. Fig. 2 is a side view on an enlarged scale of the outer end of the rocking lever showing a bearing head. Fig. 3 80 of the lower cross bar with its bearing heads. Fig. 4^a is an end view thereof. Fig. 5 is a face view of one of the double stirrups or side arms.

Referring to the drawings and especially to Fig. 1, the numeral 1 represents a double frame, composed of two triangular side frames, having their apices 2 provided with bearings for the trunnions or stub shaft of 90 the bell crank rocker lever 3. The lower arm of this rocker lever, indicated at 3a, is connected by adjustable mechanism 4 to the pull rod 5 by means of which motion is communicated to the rocker and thence to the 95 pump. The upper arm 3^b of the rocker carries a metal head upon which is the usual arc-shaped guide, which however in this case is unnecessary and may be dispensed with.

Upon each side of the rocker head is a 100 bearing head 8, and upon each of these bearing heads is hung a stirrup 9 forming the upper terminus of a side arm or link 10, which has at its lower end another stirrup 11 for engagement with a similar bearing 105 head 12 of a cross arm 13. In order to prevent displacement of the stirrups from the bearing heads 8 and 12, I provide each of the former with an upraised flange 8a and each of the latter with a similar upwardly 110 extending flange 12a. The cross arm 13 is centrally drilled at 14 to receive the polish

or sucker rod 7 being attached thereto in any suitable manner, as by means of a clamp

upon the rod above the cross arm.

The operation of my invention will now 5 be understood. At each stroke of the pull rod 5, (which is actuated by a suitable prime mover), the rocker arm 3 turns upon its pivot 2 and lifts the bearing heads 8 through an arc having its center in the pivot. The 10 bearing heads 8 rock in the stirrups 9 and lift the side arms 10 which lift the cross arm 13, and that in turn lifts the sucker rod. As the bearing head 8 rocks in the stirrup 9, different portions of the under face of the 15 stirrup bar come in contact with and rest upon different portions of the upper face of the bearing head, according to the shape of the contiguous bearing faces.

As shown, the point of support shifts from 20 the inner edge of the bearing head at the beginning of the stroke to the outer edge at the end thereof; and so long as this amplitude is equal to the horizontal displacement due to the arc of stroke, the pull of the 25 sucker rod will be vertical at all times.

Sundry advantages will be at once apparent after reading this description of my improvement. In the first place, it is cheaper than the old construction because the arms 30 may be made as simple castings. In the second place it is simpler and easier to gear up and ungear, there being no nuts, and no necessity for wrenches or other tools. In the third place, the life of all the parts is 35 lengthened, and especially the bearing parts of the swinging joint. These are usually the first to wear out in the entire jack, beside involving the necessity for constant oiling and adjusting. In my case none of this 40 is necessary.

I am aware that some changes can be made in shape and other matters of detail as well as in the method of applying my bearings and connecting parts to jacks and other 45 machines, and I wish it distinctly understood that all such as do not depart from the spirit of my invention are within the scope and purview of the appended claims.

Having thus described my invention what 50 I claim and desire to secure by Letters Pat-

ent is—

1. A pumping jack comprising in combination the following instrumentalities: a frame, a rocker lever journaled in said 55 frame, a pull rod and source of power therefor, a polish rod, bearing heads on the rocker lever, each having a portion of its periphery shaped to form a bearing surface, a cross arm on the polish rod carrying similar bear-60 ing heads, and links passing over and adapted to rock with rolling contact on the bearing surfaces of said heads so as to constitute a substantially frictionless parallel motion, substantially as described.

2. A pumping jack comprising the follow-

ing instrumentalities: a frame, a bell crank rocker lever journaled at its angle in said frame, a pull rod connected to one extremity of said lever, a polish or sucker rod, together with broad-faced bearing heads on 70 the upper end of the rocker lever, an apertured cross arm receiving and holding the polish rod, broad-faced bearing heads on the said cross arm, side links having terminal. stirrups passing over said bearing heads 75 with their inner surfaces resting and adapted to rock upon the broad faces of the heads, said faces and stirrups having such curvature, and being so proportioned that in all positions of the polish rod power will be de- 80 livered from the upper to the lower stirrups in a vertical line.

3. A jack motion comprising the following instrumentalities: a frame or support carrying bearings, a rocker member journaled 85 at one point in said bearings and means to oscillate the same therein, a bearing head on the oscillating member having an extended bearing surface curved on a radius greater than its own greatest dimension and 90 adapted as a whole to swing in the arc of a circle, a reciprocatory member adapted to move in a line tangent to said arc, a bearing head on said reciprocatory member arranged so that its axis is parallel at all 95 points of its travel to that of the bearing head on the rocker member, and a link connection between the two bearing heads with a stirrup taking over the bearing on the rocker head and adapted to rock thereon so 100 as to constantly shift its point of support toward and away from the center of oscillation of the rocker, sufficiently to compensate for the recession and approach of the rocker head from and to the line of motion of the 105 reciprocatory member during oscillation; whereby for all positions of the rocker mem-

4. A jack motion comprising the follow- 110 ing instrumentalities: a frame or support carrying bearings, a rocker member journaled at one point in said bearings and means to oscillate the same therein, a bearing head on the oscillating member with an 115 arc-shaped cam surface having its axis of curvature parallel to the axis of oscillation, a reciprocatory member adapted to move in a line meeting the arc of oscillation in at least one point, a bearing head on said recip- 120 rocatory member arranged so that its axis is parallel at all points of its travel to that of the bearing head on the cam surface, and an intermediate power transmitting member connecting the two bearing heads, with an 125 extended arc-shaped cam surface resting and adapted to rock on the cam surface of the rocker-member-bearing-head during its oscillation so as to constantly shift its point of support toward and away from the center 130

ber, power will be delivered to the reciproca-

tory member in the direct line of its motion.

of oscillation of the rocker sufficient to compensate for the recession and approach of the rocker head from and to the line of motion of the reciprocatory member; whereby 5 for all positions of said rocker member, power will be delivered to the reciprocatory member in the direct line of its motion.

In testimony whereof I affix my signature in presence of two witnesses.

HERBERT G. SMITH.
