(57) **ABSTRACT**

The present disclosure relates to a method for forming an interconnect structure. In some embodiments, the method may be performed by forming an opening within a sacrificial layer. The sacrificial layer is over a substrate. A conductive material is formed within the opening and over the sacrificial layer. The conductive material within the opening defines a conductive body. The conductive material is patterned to define a conductive projection extending outward from the conductive body. The sacrificial layer is removed and a dielectric material is formed surrounding the conductive body and the conductive projection.

REFERENCE TO RELATED APPLICATIONS

This Application is a Continuation of U.S. application Ser. No. 15/153,967 filed on May 13, 2016, which is a Continuation of U.S. application Ser. No. 14/218,060 filed on Mar. 18, 2014 (now U.S. Pat. No. 9,373,586 issued on Jun. 21, 2016), which is a Continuation-In-Part of U.S. application Ser. No. 13/676,260 filed on Nov. 14, 2012 (now U.S. Pat. No. 8,728,936 issued on May 20, 2014). The contents of the above-referenced applications are hereby incorporated by reference in their entirety.

BACKGROUND

As the density of semiconductor devices increases and the size of circuit elements becomes smaller, the resistance capacitance (RC) delay time increasingly dominates the circuit performance. To reduce the RC delay, there is a desire to switch from conventional dielectrics to low-k dielectrics. These materials are particularly useful as intermetal dielectrics, IMDs, and as interlayer dielectrics, ILDs. However, low-k materials present problems during processing, especially during the processing of the conductive material used to make interconnects.

BRIEF DESCRIPTION OF THE DRAWINGS

FIGS. 1A-1M are partial cross sectional views illustrating steps of one embodiment of forming an interconnect structure in accordance with the disclosure.

FIG. 2 illustrates a flow diagram of some embodiments of a method for the fabrication of an interconnect structure in accordance with the disclosure.

DETAILED DESCRIPTION

The description herein is made with reference to the drawings, wherein like reference numerals are generally utilized to refer to like elements throughout, and wherein the various structures are not necessarily drawn to scale. In the following description, for purposes of explanation, numerous specific details are set forth in order to facilitate understanding. It may be evident, however, to one of ordinary skill in the art, that one or more aspects described herein may be practiced with a lesser degree of these specific details. In other instances, known structures and devices are shown in block diagram form to facilitate understanding.

Semiconductor devices are manufactured or fabricated on semiconductor wafers using a number of different processing steps to create transistor and interconnection elements. To electrically connect transistor terminals associated with the semiconductor wafer, conductive (e.g., metal) wires, conductive vias, and the like are formed in dielectric materials as part of the semiconductor device. The conductive wires and vias couple electrical signals and power between transistors, internal circuit of the semiconductor devices, and circuits external to the semiconductor device.

In forming the interconnection elements the semiconductor wafer may undergo, for example, masking, etching, and deposition processes to form the desired electronic circuitry of the semiconductor devices. In particular, multiple masking and etching steps can be performed to form a pattern of recessed areas in a dielectric layer, such as a low-k dielectric layer, on a semiconductor wafer that serve as trenches and via holes for the interconnections. A deposition process may then be performed to deposit a metal layer over the semi-

conductor wafer thereby depositing metal both in the trenches and via holes and also on the non-recessed areas of the semiconductor wafer.

Increasingly, low-k dielectric layers are used to reduce signal delay and power loss effects as integrated circuit devices are scaled down. One way this has been accomplished has been to introduce porosity or dopants into the dielectric insulating layer.

As a result, the need for lower dielectric constant materials has resulted in the development of several different types of organic and inorganic low-k materials. In particular, incorporation of low-k materials with dielectric constants less than about 3.0 has become standard practice as semiconductor feature sizes have diminished to less than 0.13 microns. As feature sizes decrease below 0.13 microns, for example to 65 nm and below, materials with dielectric constants less than about 2.5 are often used. Several different organic and inorganic low-k materials have been developed and proposed for use in semiconductor devices as insulating material having dielectric constants between about 2.2 and about 3.0.

Low-k dielectric materials, however, are susceptible to damage from the etching processes because they are softer, less chemically stable or more porous, or any combination of these factors. The plasma damage can manifest itself in higher leakage currents, lower breakdown voltages, and changes in the dielectric constant associated with the low-k dielectric material.

There is, therefore, a need in the integrated circuit manufacturing art to develop a manufacturing process whereby interconnect structures may be formed without encountering the various problems presented by porous low-K dielectric layers to improve integrated circuit device yield, performance, and reliability.

Accordingly, the present disclosure is directed to methods of fabrication of an interconnect structure. The methods provide a process for defining an interconnect structure that eliminates low-k dielectric damage caused during etching processes. The process provides the further advantage of removing etch stop or NFARC (nitrogen-free anti-reflective coating) layers, making the process more cost effective.

FIGS. 1A-1M illustrate a plurality of partial cross section diagrams illustrating one embodiment of a method of forming an interconnect structure at stages in the manufacturing process according to the disclosure. Referring to FIG. 1A, a semiconductor substrate **102** having a conductive region **103** is provided. Substrate **102** is understood to include a semiconductor wafer or substrate, comprised of a semiconductor material such as silicon or germanium, or a silicon on insulator structure (SOI). Semiconductor structure can further include one or more conductive layers (such as metal or silicon) and/or insulating layers, and one or more active or passive devices formed in or over the substrate, or the like, for example, a display substrate such as a liquid crystal display (LCD), plasma display, electro-luminescence (EL) lamp display, or a light emitting diode (LED) substrate.

Overlying substrate **102** and covering conductive region **103** is a sacrificial layer **104**. Sacrificial layer **104** comprises a homopolymer or copolymer. In one embodiment, sacrificial layer **104** comprises one or more of polyimide or P(neopentyl methacrylate-co-theylene glycol dimethacrylate copolymer (P(npMAco-EGDA)). Sacrificial layer **104** is deposited by one or more of chemical vapor deposition (CVD) or spin-on coating processes. The thickness of the sacrificial layer will be in a range of from about 10000 Å (angstroms) to about 100 Å.

A dielectric hard mask layer **108** is then deposited **106** by, for example, a CVD process, as illustrated in FIG. 1B. The dielectric hard mask layer **108** is used to pattern the sacrificial layer **104** in a subsequent photolithographic process. In

some embodiments, the dielectric hard mask layer **108** comprises a material such as silicon-oxide, silicon-nitride, silicon-oxynitride, and silicon-carbide. The dielectric hard mask layer **108** will have a thickness of from about 1000 Å to about 10 Å.

Following deposition of the hard mask layer **108**, in one embodiment, a photoresist film **112** is formed by process **110** over the hard mask layer **108**, as illustrated in FIG. 1C. Conventional photoresist materials may be used. The photoresist film **112** can be a carbon-containing, organic material. Various photoresists having various thicknesses can be utilized. Photo resist patterning and etching **114** are performed in FIG. 1D

Hard mask **108** patterning and first etching process **116** through the hard mask layer **108** and into the sacrificial layer **104** are then performed to remove a portion of sacrificial layer **104** and form a first feature defined by an opening **118** in the sacrificial layer **104**, as shown in FIG. 1E. In one embodiment, first feature comprises a trench.

In FIG. 1F, a metal layer **124** is deposited **122** over first feature and filling opening **118** in sacrificial layer **104** to form a metal body **125** therein. Metal body **125** is defined by a lower portion **124(a)** of the metal layer **124**. Metal body **125** includes angled opposing sidewalls. In some embodiments, the metal body **125** comprises a metal wire layer configured to provide for a lateral interconnection (i.e., an interconnection parallel to the surface of the semiconductor substrate **102**). In one embodiment, the metal layer **124** can be formed from elements such as aluminum (Al), tungsten (W), copper (Cu), copper manganese (CuMn), copper-titanium (CuTi), copper vanadium (CuV), copper chromium (CuCr), or copper-niobium (CuNb), and the like. Metal layer **124** can be formed using, for example, a plasma vapor deposition technique, among others. Metal layer **124** can be deposited at a thickness, in one embodiment, of from about 100 Å (Angstroms) to about 20,000 Å.

A photoresist film **112'** is formed over the metal layer **124** and patterned **126** by conventional techniques, as shown in FIG. 1G. A second etch **128** is performed to pattern and etch an upper portion **124(b)** of the metal layer **124** to form a second feature having first recesses **123(a)**, **123(b)** and defined by a vertical projection **127** extending from the metal body **125**, as illustrated in FIG. 1H.

The vertical projection **127** includes angled opposing sidewalls, **129(a)** and **129(b)**, and upper surface **130**. In some embodiments, the angled opposing sidewalls, **129(a)** and **129(b)**, are tapered such that the vertical projection **127** has a narrower top surface **127(a)** and wider bottom surface **127(b)** (i.e., $w_1 < w_2$). In some embodiments, the vertical projection **127** comprises a metal via configured to provide for a vertical interconnection between an underlying metal body and an overlying metal body.

In FIG. 1I, sacrificial layer **104** is removed by one or more of, for example, etching, wet stripping, annealing, UV or IR radiation techniques (not shown). Removal of the sacrificial layer **104** exposes angled opposing sidewalls **132(a)**, **132(b)** of metal body **125** and forms second recesses **131(a)**, **131(b)**. Angled opposing sidewalls **132(a)**, **132(b)** taper such that metal body **125** has a wider top surface **125(a)** and narrower bottom surface **125(b)**.

In one embodiment, a barrier layer **134** is formed overlying and encompassing metal body **125** and vertical projection **127** and disposed between dielectric material **136** (FIG. 1K) and metal layer **124**. By encompassing metal body **125** and vertical projection **127**, barrier layer **134** is continuous. Barrier layer **134** is formed by depositing a dielectric material, for example, silicon-nitride and silicon-carbide. In one embodiment, barrier layer **134** is formed by depositing a metal, for example, TiN, TaN, Co, WN, TiSiN, TaSiN, or combinations thereof. In another embodiment, an

annealing **135** is performed at a temperature of about greater than 200° C., such that barrier layer **134** is self-forming, as illustrated FIG. 1J. The thickness of the barrier layer **134** can be, in one embodiment, from about 1 Å (Angstrom) to about 300 Å.

In FIG. 1K, low-k dielectric material **136** is deposited by process **137** to fill first **123(a)**, **123(b)** and second **131(a)**, **131(b)** recesses and overlying the upper surface **130** of the vertical projection **127** to form a dielectric region **136'**. Low-k dielectric material **136** thus encapsulates vertical projection **127** and metal body **125**. The low-k dielectric includes dielectrics with k less than about 3. Such dielectrics include, for example, carbon-doped silicon dioxide, also referred to as organosilicate glass (OSG) and carbon-oxide. Low-k materials may also include borophosphosilicate glass (BPSG), boro silicate glass (BSG), and phosphosilicate glass (PSG), among others. The dielectric layer **136** may be formed using, for example, tetraethyl orthosilicate (TEOS), chemical vapor deposition (CVD), plasma enhanced CVD (PECVD), low pressure CVD (LPCVD), or spin-on coating techniques. The thickness of the low-k dielectric will be, in one embodiment, from about 100 Å to about 20000 Å.

In the embodiment illustrated in FIG. 1K, at least one air gap **138** is formed within the dielectric material **136**. The air gap **138** is disposed in the dielectric region **136'** between angled sidewalls **132(a)**, **132(b)** of adjacent metal bodies **125**. Air gap **138** can be self-forming during deposition of the low-k material **136**. In one embodiment, the size of the air gap can be from about 0 Å to about 20000 Å. It is contemplated, however, that the size of the air gap can be controlled by the low-k material **136** deposition process. A chemical mechanical polishing (CMP) process can then be performed to remove excess dielectric layer **136** and expose upper surface **130** of vertical projection **127**, as illustrated in FIG. 1L.

Following CMP process, the method can be repeated to form an additional metal layer **150** of an interconnect structure **152** overlying vertical projection **127** and electrically coupled to the vertical projection **127**, as illustrated in FIG. 1M, so as to form an integrated circuit of at least two adjacent interconnect structures, **148** and **152**.

FIG. 2 illustrates a flow diagram of some embodiments of a method **200** for formation of a semiconductor structure according to an embodiment of the present disclosure. While method **200** is illustrated and described below as a series of acts or events, it will be appreciated that the illustrated ordering of such acts or events are not to be interpreted in a limiting sense. For example, some acts may occur in different orders and/or concurrently with other acts or events apart from those illustrated and/or described herein. In addition, not all illustrated acts may be required to implement one or more aspects or embodiments of the description herein. Further, one or more of the acts depicted herein may be carried out in one or more separate acts and/or phases.

At step **202** a semiconductor substrate is provided. A sacrificial layer is then formed over the substrate at step **204**.

At step **206**, a hard mask layer is deposited overlying the sacrificial layer.

At step **208**, a first feature is formed by patterning and etching through hard mask and sacrificial layer to form an opening in the sacrificial layer.

At step **210**, a metal layer is deposited overlying first feature and filling the feature opening.

At step **212**, an upper portion of the metal layer is patterned and etched to form a second feature.

At step **214**, sacrificial layer is removed.

At step **216**, a barrier layer is formed by CVD, PVD, MOCVD or ALD, or barrier layer can be self-formed by annealing.

5

At step **218**, a low-k dielectric material is deposited to fill recesses and encompass metal body and vertical projection.

At step **220**, at least one air gap is formed in the low-k dielectric material. The air gap is disposed in the dielectric region between adjacent interconnect structures.

At step **222**, a CMP process is performed to remove excess dielectric layer and expose a top surface of the vertical projection. The method then ends.

It will be appreciated that equivalent alterations and/or modifications may occur to one of ordinary skill in the art based upon a reading and/or understanding of the specification and annexed drawings. The disclosure herein includes all such modifications and alterations and is generally not intended to be limited thereby. In addition, while a particular feature or aspect may have been disclosed with respect to only one of several implementations, such feature or aspect may be combined with one or more other features and/or aspects of other implementations as may be desired. Furthermore, to the extent that the terms “includes”, “having”, “has”, “with”, and/or variants thereof are used herein, such terms are intended to be inclusive in meaning—like “comprising.” Also, “exemplary” is merely meant to mean an example, rather than the best. It is also to be appreciated that features, layers and/or elements depicted herein are illustrated with particular dimensions and/or orientations relative to one another for purposes of simplicity and ease of understanding, and that the actual dimensions and/or orientations may differ substantially from that illustrated herein.

Therefore, the disclosure relates to method for forming a conductive interconnect structure, and a related apparatus.

In some embodiments, the present disclosure relates to a method for forming an interconnect structure. The method comprises forming an opening within a sacrificial layer that is over a substrate, and forming a conductive material within the opening and over the sacrificial layer. The conductive material within the opening defines a conductive body. The method further comprises patterning the conductive material to define a conductive projection extending outward from the conductive body, and removing the sacrificial layer. The method further comprises forming a dielectric material surrounding the conductive body and the conductive projection.

In other embodiments, the present disclosure relates to a method for forming an interconnect structure. The method comprises etching one or more sacrificial materials over a substrate to define an opening extending through the one or more sacrificial materials. The method further comprises forming metal within the opening and over the one or more sacrificial materials. The metal within the opening defines a metal body. The method further comprises selectively etching the metal to define a metal projection extending from the metal body. The metal projection is set back from sidewalls of the metal body. The method further comprises removing the one or more sacrificial materials to expose opposing sidewalls of the metal body, and forming a dielectric material surrounding the metal body and the metal projection.

In yet other embodiments, the present disclosure relates to an integrated chip. The integrated chip comprises a copper body over a substrate, and a copper projection disposed on and in contact with the copper body. The copper projection has angled sidewalls that cause a width of the copper projection to decrease as a distance from the copper body increases. The copper body laterally extends past the angled sidewalls of the copper projection.

What is claimed is:

1. A method for forming an interconnect structure, comprising:

forming an opening within a sacrificial layer, the sacrificial layer being over a substrate;

6

forming a conductive material within the opening and over the sacrificial layer, wherein the conductive material within the opening defines a conductive body; patterning the conductive material to define a conductive projection extending outward from the conductive body;

removing the sacrificial layer; and

forming a dielectric material surrounding the conductive body and the conductive projection.

2. The method of claim **1**, wherein the removing of the sacrificial layer exposes a sidewall of the conductive body.

3. The method of claim **1**, wherein the sacrificial layer comprises a homopolymer or copolymer.

4. The method of claim **1**, wherein the removing of the sacrificial layer exposes an upper surface of the substrate.

5. The method of claim **1**, further comprising:

depositing a hard mask layer over the sacrificial layer; patterning the hard mask layer to form a patterned hard mask layer; and

etching the sacrificial layer according to the patterned hard mask layer to form the opening in the sacrificial layer.

6. The method of claim **1**, further comprising:

forming a patterned photoresist layer over the conductive material; and

etching the conductive material according to the patterned photoresist layer to define the conductive projection.

7. The method of claim **1**, wherein the conductive material comprises copper and manganese.

8. The method of claim **1**,

wherein the conductive projection comprises angled sidewalls that give the conductive projection a width that decreases as a distance from the conductive body increases; and

wherein the conductive body laterally extends past the angled sidewalls of the conductive projection.

9. The method of claim **1**, further comprising:

concurrently forming a barrier layer over the conductive body and the conductive projection after the removing of the sacrificial layer.

10. The method of claim **9**, wherein the barrier layer comprises a self-forming barrier formed by annealing the conductive body and the conductive projection at a temperature of greater than approximately 200° C.

11. The method of claim **9**, wherein the barrier layer continuously extends along sidewalls and upper surfaces of the conductive body and the conductive projection.

12. A method for forming an interconnect structure, comprising:

etching one or more sacrificial materials over a substrate to define an opening extending through the one or more sacrificial materials;

forming metal within the opening and over the one or more sacrificial materials, wherein the metal within the opening defines a metal body;

selectively etching the metal to define a metal projection extending from the metal body, wherein the metal projection is set back from sidewalls of the metal body;

removing the one or more sacrificial materials to expose opposing sidewalls of the metal body; and

forming a dielectric material surrounding the metal body and the metal projection.

13. The method of claim **12**, further comprising:

performing a planarization process to remove the dielectric material from directly over the metal projection and to expose a topmost surface of the metal projection.

7

14. The method of claim 12, wherein the metal completely covers the one or more sacrificial materials prior to the selectively etching of the metal.

15. The method of claim 12, further comprising:
removing the one or more sacrificial materials using one
or more of etching, wet stripping, annealing, ultraviolet
(UV) radiation, and infrared (IR) radiation.

16. The method of claim 12, wherein the metal projection comprises angled sidewalls, which cause a width of the metal projection to decrease as a distance from the metal body increases.

17. The method of claim 12, further comprising:
concurrently forming a barrier layer over the metal body
and the metal projection after the removing of the one
or more sacrificial materials.

18. A method for forming an interconnect structure,
comprising:
forming an opening within a sacrificial material over a
substrate;

8

forming a conductive material within the opening and
over the sacrificial material;
patterning the conductive material to define upper side-
walls that protrude outward from horizontally extend-
ing surfaces of the conductive material;
removing the sacrificial material; and
forming a dielectric material around the conductive mate-
rial.

19. The method of claim 18, wherein the upper sidewalls
of the conductive material are tapered so that an upper width
of the conductive material above the horizontally extending
surfaces decreases as a distance from the substrate increases.

20. The method of claim 19, wherein the conductive
material has lower sidewalls below the horizontally extend-
ing surfaces, which are tapered so that a lower width of the
conductive material below the horizontally extending sur-
faces increases as the distance from the substrate increases.
