(57) **ABSTRACT**

An implantable medical device includes operational cir-
cuitry, such as a therapy circuit. The implantable medical
device also includes a power source configured to deliver
energy to the operational circuitry, and a deactivation ele-
ment configured to disable the therapy circuit. A power
manager is configured to detect an end-of-life condition of
the power source and, in response to detecting the end-of-
life condition, cause the deactivation element to reversibly
disable the therapy circuit.

**LEADLESS PACEMAKER WITH
END-OF-LIFE PROTECTION****CROSS-REFERENCE TO RELATED
APPLICATION**

This application claims priority to Provisional Application Nos. 61/919,572; 61/919,575; and 61/919,567, all of which were filed on Dec. 20, 2013, and each of which is herein incorporated by reference in its entirety.

TECHNICAL FIELD

The present invention relates to an implantable system having an implantable medical device. More specifically, the invention relates to managing and end-of-life condition associated with an implantable medical device.

BACKGROUND

Implantable medical devices include, among other things, cardiac rhythm management (CRM) devices such as pacers, cardioverters, defibrillators, cardiac resynchronization therapy (CRT) devices, leadless pacing seeds, as well as combination devices that provide more than one of these therapy modalities to a subject. Such implantable devices are typically powered by a battery. As the battery's useful life becomes exhausted, the implanted device may malfunction, causing errors in the therapy it provides and/or its communication with other devices.

SUMMARY

In Example 1, the present disclosure describes an implantable medical device comprising operational circuitry, wherein the operational circuitry comprises at least one of a therapy circuit and a sensor circuit. The implantable medical device also includes a communications module, a power source configured to deliver energy to the operational circuitry, and a deactivation element configured to at least partially disable the operational circuitry by interrupting delivery of energy from the power source to the operational circuitry. A power manager disposed within the specification is configured to detect an end-of-life condition of the power source and, in response to detecting the end-of-life condition, cause the deactivation element to at least partially reversibly disable the operational circuitry.

In Example 2, the implantable medical device of Example 1, wherein the implantable medical device comprises a leadless cardiac pacing seed.

In Example 3, the implantable medical device of Example 1, wherein the operational circuitry comprises the therapy circuit.

In Example 4, the implantable medical device of Example 3, wherein the deactivation element is configured to prevent energy from being delivered to the therapy circuit.

In Example 5, the implantable medical device of Example 1, further comprising a memory component configured to store an indication of a post end-of-life state of the implantable medical device.

In Example 6, the implantable medical device of Example 5, wherein the memory component comprises an active storage element.

In Example 7, the implantable medical device of Example 6, wherein the power manager is configured to allow energy to be delivered to the memory component during the end-of-life state.

2

In Example 8, the implantable medical device of Example 5, wherein the memory component comprises a non-volatile memory element.

In Example 9, the implantable medical device of Example 9, wherein the memory component is further configured to store a plurality of operational parameters during the end-of-life state.

In Example 10, the implantable medical device of Example 10, wherein the power source comprises a rechargeable battery.

In Example 11, the implantable medical device of Example 11, further comprising a controller, wherein the controller is configured to access the plurality of operational parameters in response to receiving an activation signal.

In Example 12, the implantable medical device of Example 11, wherein the controller is configured to restore the device to its pre-end-of-life state using the operational parameters.

In Example 13, the present disclosure describes a leadless cardiac pacing seed comprising a therapy circuit, a communications module, and a power source configured to deliver energy to the therapy circuit and the communications module. The leadless cardiac pacing seed also includes a deactivation element configured to disable at least one of the therapy circuit and the communications module by reversibly interrupting delivery of energy from the power source to the therapy circuit or the communications module. A power manager disposed within the leadless cardiac pacing seed is configured to detect an end-of-life condition of the seed and, in response to detecting the end-of-life condition, cause the deactivation element to reversibly disable at least one of the therapy circuit and the communications module.

In Example 14, the leadless cardiac pacing seed of Example 13, further comprising a memory component configured to store an indication of an end-of-life state.

In Example 15, the leadless cardiac pacing seed of Example 14, wherein the memory component comprises an active storage element.

In Example 16, the leadless cardiac pacing seed of Example 15, wherein the power manager is configured to allow energy to be delivered to the memory component during the end-of-life state.

In Example 17, the leadless cardiac pacing seed of Example 14, wherein the memory component comprises a non-volatile memory element.

In Example 18, the leadless cardiac pacing seed of Example 17, wherein the memory component is further configured to store a plurality of operational parameters during the end-of-life state, and wherein the controller is configured to access the plurality of operational parameters in response to receiving an activation signal.

In Example 19, the leadless cardiac pacing seed of Example 18, wherein the controller is configured to restore the device to its pre-end-of-life state using the operational parameters.

In Example 20, the present disclosure describes a cardiac pacing system comprising an implantable leadless cardiac pacing seed configured to deliver electrostimulation therapy to a patient and an external device. The implantable leadless cardiac pacing seed includes a therapy circuit, a communications module configured to receive a deactivation signal from the external device, and a power source configured to deliver energy to the therapy circuit and the communications module. A power manager is configured to detect an end-of-life condition of at least one of the power source and the therapy circuit and, in response to detecting the end-of-life condition, place the implantable leadless cardiac pacing seed

in an end-of-life state. The implantable leadless cardiac pacing seed also includes a deactivation element configured to interrupt delivery of energy from the power source to the therapy circuit so as to reversibly disable the therapy circuit in response to the deactivation signal being received by the communications module. Additionally, the leadless cardiac pacing seed includes a memory component configured to store an indication of an end-of-life state of the seed.

While multiple embodiments are disclosed, still other embodiments of the present invention will become apparent to those skilled in the art from the following detailed description, which shows and describes illustrative embodiments of the invention. Accordingly, the drawings and detailed description are to be regarded as illustrative in nature and not restrictive.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic illustration of an implantable system having a leadless implantable stimulator and a control device in an implanted state, in accordance with embodiments of the invention;

FIG. 2 is a schematic block diagram of an implantable system having an IMD and a control device, in accordance with embodiments of the invention;

FIG. 3 is a schematic block diagram of an IMD, in accordance with embodiments of the invention;

FIG. 4 is a flow diagram depicting an illustrative method of managing an end-of-life state of an IMD, in accordance with embodiments of the invention;

FIG. 5 is another flow diagram depicting an illustrative method of managing an end-of-life state of an IMD, in accordance with embodiments of the invention;

FIG. 6 is a schematic block diagram of an IMD, in accordance with embodiments of the invention;

FIG. 7 is a schematic block diagram of an IMD, in accordance with embodiments of the invention;

FIG. 8 is a flow diagram depicting an illustrative method of deactivating an IMD, in accordance with embodiments of the invention;

FIG. 9 is another flow diagram depicting an illustrative method of deactivating an IMD, in accordance with embodiments of the invention;

FIG. 10 is a schematic block diagram depicting an illustrative implantable leadless pacing system, in accordance with embodiments of the invention;

FIG. 11 is a flow diagram depicting an illustrative method of replacing a first IMD with a second IMD;

FIG. 12 is a flow diagram depicting an illustrative method of mitigating the effects from a loss of a leadless pacing seed, in accordance with embodiments of the invention;

FIG. 13 is a schematic circuit diagram depicting an illustrative circuit arrangement for an implantable medical device, in accordance with embodiments of the invention; and

FIG. 14 is another schematic circuit diagram depicting an illustrative circuit arrangement for an implantable medical device, in accordance with embodiments of the invention.

Various modifications and additions can be made to the exemplary embodiments discussed without departing from the scope of the present invention. For example, while the embodiments described above refer to particular features, the scope of this invention also includes embodiments having different combinations of features and embodiments that do not include all of the described features. Accordingly, the scope of the present invention is intended to embrace all

such alternatives, modifications, and variations as fall within the scope of the claims, together with all equivalents thereof.

DETAILED DESCRIPTION

FIG. 1 is a schematic illustration of an implantable system 100 including an implantable medical device (IMD) 102 implanted within a chamber of a patient's heart 104. In the embodiment illustrated in FIG. 1, the IMD 102 is a wireless electrode stimulator assembly, referred to herein, interchangeably, as a "seed." The system 100 also includes a co-implanted device 106 that is configured to communicate with the seed 102. In various embodiments, the co-implanted device 106 can be implanted subcutaneously within an implantation location or pocket in the patient's chest or abdomen. The co-implanted device 106 may be an implantable medical device known in the art or later developed, for delivering an electrical therapeutic stimulus to the patient. In various embodiments, the co-implanted device 106 may provide therapy and/or diagnostic data about the patient and/or the co-implanted device 106. In various embodiments, the co-implanted device 106 may be a communication repeater for extra-corporeal communication to external device 108. In various embodiments, the co-implanted device 106 may be a pacemaker, an implantable cardioverter defibrillator (ICD) device, or a cardiac resynchronization therapy (CRT) device. In various embodiments, the implantable control device 106 may include both defibrillation and pacing/CRT capabilities (e.g., a CRT-D device).

In embodiments, the co-implanted device 106 includes circuitry to sense and analyze the heart's electrical activity, and to determine if and when a pacing electrical pulse needs to be delivered and, in embodiments having multiple seeds 102, by which of the seeds 102 the pulse should be delivered. The sensing capability may be made possible by having sense electrodes included within the physical assembly of the co-implanted device 106. Alternatively, a conventional single or dual lead pacemaker (not shown in FIG. 1) may sense the local cardiac electrocardiogram (ECG) and transmit this information to the co-implanted device 106 for use in determination of the timing of seed firing. In embodiments, the seed 102 may include sensing capability, and may communicate sensed information to other seeds 102 and/or to the co-implanted device 106. In embodiments, the co-implanted device 106 may transmit charge energy and data, such as pace trigger signals, pacing amplitude information, and pulse width information to the seed 102 via radio-frequency (RF) communications, acoustic communications, inductive communications, electrical communications, microwave communications, conductive communications, and/or the like.

In the embodiment shown in FIG. 1, the seed 102 is implanted in the right ventricle 110. The seed 102 may sense electrical signals of the heart 104 and/or deliver electrical pulses to the heart 104 in an attempt to correct an arrhythmia and restore sinus rhythm. In other embodiments, the seed 102 may be implanted or placed within any chamber of the heart 104. For example, the seed 102 may be implanted in the right atrium 112, the left ventricle 114, or the left atrium 116. In addition, the seed 102 may be implanted into or be placed on the epicardium 118, for example the epicardium 118 of the right ventricle 110, the right atrium 112, the left ventricle 114 or the left atrium 116. In such cases, the seed 102 can be delivered through the circulatory system of the heart 104 to the location of interest, or it can be implanted or placed on the epicardium 118 by gaining access to the pericardial space. In some embodiments, the seed 102 may

be implanted through the epicardium **118** or endocardium **120** and into the myocardium **122**. In other embodiments, the system **100** may include a plurality of seeds **102**, each placed in, implanted in, or attached to a different chamber or a different part of the heart **104**.

In embodiments, implantable systems such as implantable system **100** may be unipolar, multipolar (e.g., bipolar, quad-polar, etc.) or configurable such that a unipolar or multipolar operation can be selected. In a unipolar system, an electrode of the seed **102** acts as one pole of an electrical system, and the second pole of the electrical system may be located remotely from the electrode. For example, the second pole of the electrical system may be located on the housing of the seed **102** or on a wire connected to the seed **102**. Various other configurations for unipolar devices are known in the art.

In a bipolar system, the implantable system **100** may have two or more electrodes disposed near the site of treatment. For example, a seed **102** may have two electrodes disposed on the body of the seed **102** (e.g., a tip electrode and a ring electrode). The two electrodes may act as the two electrical poles of the seed **102**. Various other configurations for bipolar electrodes are known in the art. According to embodiments, the electrodes of the seeds **102** also may be configured to sense certain physiological attributes of the heart **104**. For example, the heart's **104** natural electrical signals can be received by an electrode and transmitted to a remote location (e.g., the co-implanted device **106**). In addition, other sensing mechanisms that are known in the art may be placed within, on or near the seeds **102**, and may include, for example, pressure sensors, motion sensors, and/or the like. Although the seed **102**, and corresponding system **100**, illustrated in FIG. **1** is configured for cardiac therapy, other implantable seed applications, such as those configured for neurostimulation, e.g., Spinal Cord Stimulation (SCS), Deep Brain Stimulation (DBS), and Functional Electrical Stimulation (FES), also are contemplated within the scope of various embodiments.

In embodiments, the seed **102** has an internal receiver that may receive communications and/or energy from co-implanted device **106**, which may include a transmitter. The co-implanted device **106** may include a pulse generator that supplies an appropriate time-varying energy (e.g., current or voltage) to the seed **102**. The seed **102** may include a power source for storing electrical energy, and may also have a triggering mechanism to deliver stored electrical energy to adjacent heart tissue.

FIG. **2** is a block schematic diagram of a system including an IMD **200** (such as, for example, the seed **102** depicted in FIG. **1**) and a co-implanted device **202**. As illustrated in FIG. **2**, the IMD **200** includes a power component **204** that provides electrical energy to a set **206** of components. The set **206** of components include a controller **208**, a memory **210**, a communications component **212**, a therapy circuit **214**, and a power manager **216**. As shown in FIG. **2**, the therapy circuit **214** is coupled to electrodes **218** and **219** and is configured to provide stimulation energy to the electrodes, which, in turn, provides the energy to a patient's body (e.g., a location in a patient's heart). According to embodiments, the IMD **200** may include more than two electrodes. The power component **204** includes a power source **220** configured to store electrical energy and a deactivation element **222** configured to prevent, upon its activation, energy from being delivered to one or more components (e.g., the controller **208**, the communications component **212**, the therapy circuit **214**) of the IMD **200**. According to embodiments, the power source **220** may include one or more batteries,

capacitors, and/or the like. In embodiments, the IMD **200** may include other components such as, for example, one or more sensor circuits (not shown), coupled to one or more sensors and/or the electrodes **218** and **219**, for sensing physiological parameters.

According to embodiments, the power manager **216** may be configured to detect an end-of-life (EOL) condition associated with the IMD **200**. In embodiments, the power manager **216** may detect an EOL condition by determining that the capacity of the power source has been depleted below a predetermined threshold (e.g., 10% of total capacity), that the operation of one or more components (e.g., the controller **208**, the therapy circuit **214**, and/or the communications component **212**) appears to be altered due to a deficiency of energy being delivered from the power source **220**, and/or the like. In embodiments, the power manager **216** may monitor the operation of various components of the IMD **200** by accessing data from the controller **208**. In other embodiments, the power manager **216** may monitor the operation of components directly.

According to various embodiments, the deactivation element **222** may comprise one or more elements, circuits, logical components, and/or the like, and may be configured to prevent electrical energy from being delivered from the power source **220** or to one or more components of the IMD **200**. In embodiments, for example, the deactivation element **222** may be, or include, a short-circuit element (e.g., a fuse), a switch (e.g., a field-effect-transistor (FET) fuse), a crowbar mechanism, and/or the like. The deactivation element **222** may be configured to selectively prevent electrical energy from being delivered to certain components of the IMD **200** and, in embodiments, the deactivation element **222** may be configured to prevent electrical energy from being delivered to all of the components of the IMD **200**. The deactivation element **222** may, in embodiments, be configured to permanently and/or reversibly prevent electrical energy from being delivered to one or more components of the IMD **200**. In embodiments, the power manager **216** may control the operation of the deactivation element **222**.

The deactivation element **222**, which may include one or more circuit elements that require electric energy to function, may be powered by the power source. For example, as indicated above, the deactivation element **222** may include a fuse that, blows upon being provided with a predetermined amount of energy, thereby permanently preventing electrical energy from being provided to one or more of the components of the IMD **200**. This energy may be provided by the power source **220**, in response to a signal from the power manager **216**. In other embodiments, the deactivation element **222** may include a switch that requires energy to be activated, which may be provided by the power source **220**. In these and other implementations, as the power source **220** becomes depleted, it may reach a condition in which it does not include enough power to activate the deactivation element **222**. According to embodiments, a predetermined amount, or range, of energy may be sequestered for use in activating the deactivation element **222**.

The co-implanted device **202** includes a communications component **224** having circuits and one or more transmitters and/or receivers for communicating wirelessly with the seed **200**. The communications component **212** of the IMD **200** includes a transceiver **226** and an antenna **228** (or multiple antennae) that work together to facilitate wireless communication **230** with the co-implanted device **202**, which may include one or more implantable co-implanted devices (e.g., the co-implanted device **106** depicted in FIG. **1**) and/or an external device (e.g., the external device **108** depicted in

FIG. 1). In embodiments, the communications component **212** may also facilitate communications with other IMDs **200** (e.g., other seeds) such as, for example, to facilitate coordinated operations between the IMDs. According to various embodiments, the communications component **212** may include one or more transmitters, receivers, transceivers, transducers, and/or the like, and may be configured to facilitate any number of different types of wireless communication such as, for example, radio-frequency (RF) communication, microwave communication, infrared communication, acoustic communication, inductive communication, conductive communication, and/or the like. The communications component **224** may, in addition to facilitating wireless (e.g., RF, microwave, acoustic, etc.) communication with the IMD **200**, facilitate wireless communication with an external device (e.g., the external device **130** depicted in FIG. 1), such as a programming device, such that information may be provided to the co-implanted device **202** or supplied to the external device. In embodiments, the communications component **224** may include an antenna disposed on or in the co-implanted device **202** or on a distal portion of an attached lead (not shown).

In an implementation, the co-implanted device **202** includes a controller **232** that may include, for example, a processing unit, a pulse generator, and/or the like. The controller **232** may be a programmable micro-controller or microprocessor, and may include one or more programmable logic devices (PLDs) or application specific integrated circuits (ASICs). The controller **232** may execute instructions and perform desired tasks as specified by the instructions. The controller may also be configured to store information in the memory **234** and/or access information from the memory **234**. The memory **234** may include volatile and/or non-volatile memory, and may store instructions that, when executed by the controller **232** cause methods and processes to be performed by the co-implanted device **202**. For example, in embodiments, the controller **232** may process instructions and/or data stored in the memory **234** to control delivery of an electrical stimulation therapy by the IMD **200**. Additionally, the co-implanted device **202** may sense physiological parameters and/or deliver therapy using a sensor/therapy circuit **236** that may be coupled, for example, to electrodes **238** and **239**, a sensor (not shown), or a combination of these. In embodiments, the sensor/therapy circuit **236** may actually include multiple circuits. The memory **234** may be used to store pacing parameters and sensed information according to some implementations. The co-implanted device **202** may also include a power source (e.g., a battery) (not shown) that supplies power to the circuits and components of the co-implanted device **202**. In some implementations, the controller **232** may include memory as well. Although the present system is described in conjunction with a co-implanted device **202** having a microprocessor-based architecture, it will be understood that the co-implanted device **202** (or other device) may be implemented in any logic-based integrated circuit architecture, if desired.

The controller **232** may include digital-to-analog (D/A) converters, analog-to-digital (A/D) converters, timers, counters, filters, switches, etc. (not shown). The controller **232**, sensor/therapy circuit **236** (e.g., sensing circuits), memory **234**, and communications component **224** may work together to control communication between the co-implanted device **202** and one or more leadless electrode assemblies (e.g., IMD **200**) to facilitate providing pacing stimuli to the heart. In an implementation, the controller **232** may encode information, such as a unique identifier, pacing

threshold information, pulse width information, pacing trigger signals, demand pacing information, pace timing information, and the like, to be transmitted to the seed **200**.

Information from sense circuits included in the sensor/therapy circuit **236** may be used to adjust pacing or communications parameters. The sense circuits may amplify and filter signals sensed from sensors positioned in the right or left atrium, or in the right or left ventricle, or from sensors on an external surface of the pacing controller. As is conventional, the sense circuits may include one or more A/D converters. The sensors may be attached to leads implanted within, on, or near the heart, and in some implementations the seed **200** may include sensors and may transmit sensed information to the co-implanted device **202** directly or through a lead that includes a receiver. In some implementations, the seed electrodes that deliver pacing energy to the tissue are the same as the sense electrodes used to sense the local electrical voltage at the pacing site. In these cases, sensing may be paused when pacing energy is being delivered. Similarly, the transmitter/receiver that receives communications may be the same as the transmitter/receiver that sends sensed information back to the co-implanted device **202**, according to some implementations. In these cases, outgoing transmissions may be paused when communications are being received. The sensor/therapy circuit **236** of the co-implanted device **202** may include, for example, one or more can or housing electrodes disposed on an exterior surface of the co-implanted device **202**.

In embodiments, for example, the controller **232** may receive, via the communications component **224**, an indication of an EOL condition corresponding to an IMD **200**, which the controller **232** may store in the memory **234**. Based on the indication of the EOL condition of the IMD **200**, the controller **232** may determine a modified therapy program and/or communication structure associated with additional IMDs and provide, via the communications component **224**, operational parameters corresponding to the new program and/or structure to the additional IMDs, an external device, and/or the like. In this manner, therapy programs and communication structures may be modified to compensate for the loss of an IMD **200** such as, for example, when the power source of an IMD **200** depletes such that the IMD **200** reaches an EOL condition.

The illustrative IMD **200** and co-implanted device **202** shown in FIG. 2 are not intended to suggest any limitation as to the scope of use or functionality of embodiments of the invention disclosed throughout this document. Neither should the illustrative IMD **200** and co-implanted device **202** be interpreted as having any dependency or requirement related to any single component or combination of components illustrated therein. For example, in embodiments, the illustrative IMD **200** may include additional components such as, for example, a sensor circuit (not illustrated). Additionally, any one or more of the components depicted in FIG. 2 can be, in embodiments, integrated with various ones of the other components depicted therein (and/or components not illustrated). Any number of other components or combinations of components can be integrated with the illustrative IMD **200** and/or co-implanted device **202** depicted in FIG. 2, all of which are considered to be within the scope of this disclosure.

FIG. 3 is a schematic block diagram of an IMD **300** illustrating aspects of embodiments of the invention. As shown in FIG. 3, the IMD **300** includes a power component **302** that powers operational circuitry **304** of the IMD **300**. The operational circuitry **304** includes a controller **306** coupled to a memory **308**. An oscillator **310** coupled to the

controller 306 may be used as a clocking mechanism to provide timing functions to the controller 306. In embodiments, other types of clocking mechanisms may be used as well as, or in addition, to the oscillator 310. The operational circuitry 304 also includes a communications component 312, a therapy circuit 314, and a power manager 316. As shown in FIG. 3, the therapy circuit 314 is coupled to electrodes 318 and 319 and is configured to provide stimulation energy to the electrodes, which, in turn, provide the energy to a patient's body (e.g., a location in a patient's heart). According to embodiments, the IMD 300 may include more than two electrodes. Additionally, the communications component 312 may be similar to the communications component 212 depicted in FIG. 2 and include a transceiver and an antenna. In embodiments, any number of the components illustrated in FIG. 3 may be, include, or be similar to, similarly named components depicted in FIG. 2. The IMD 300 may include any number of additional components as well such as, for example, a sensor circuit.

As shown in FIG. 3, the power component 302 includes a power source 320 coupled to a deactivation element 322. The illustrated power source 320 includes a first energy storage component 324 and a second energy storage component 326. According to embodiments, the first energy storage component 324 may include, for example, a battery, and may be configured to provide electrical energy to any one or more of the operational circuitry 304 of the IMD 300. The second energy storage component 326 may include, for example, a capacitor and/or an additional battery, and may be configured to store a predetermined amount, or range, of electrical energy for activating the deactivation element 322. In embodiments, for example, when the power manager 316 detects that an end-of-life (EOL) condition of the IMD 300 is nearing, the power manager 316 may send a signal to the power source 320 to cause a predetermined amount, or range, of electrical energy to be transferred from the first energy storage component 324 to the second energy storage component 326, which may store the energy until receiving a signal from the power manager 316 that causes the second energy storage component 326 to provide at least a portion of the stored electrical energy to the deactivation element 322, thereby activating the deactivation element 322.

In embodiments, the power manager 316 may be configured to enter a pre-EOL state in which it is configured to cause deactivation only upon the satisfaction of a trigger condition. In embodiments, for example, the trigger condition may include detecting that the first energy storage component 324 has depleted beyond a predetermined threshold; detecting an abnormality or interruption in the functionality of the therapy circuit 314, the communications component 312, the controller 306, and/or the oscillator 310; receiving a signal from a device external to the IMD 300 (e.g., another IMD, a control device, an external programmer, an external magnet, and/or the like); determining that a certain event has not occurred (e.g., determining that a predetermined signal has not been received within the passage of a certain amount of time); and/or the like.

Upon detecting the occurrence of the trigger condition, the power manager 316 may send a signal to the power component to cause the energy stored in the second energy storage component 326 to be provided to the deactivation element 322, which may be electronically, logically, and/or communicatively coupled to any one or more of the components of the operational circuitry 304 of the IMD 300. In embodiments, the transfer of energy to the deactivation element 322 may cause the deactivation element 322 to enter an EOL state, in which the deactivation element 322 pre-

vents electrical energy from being delivered to one or more components of the IMD 300. For example, the deactivation element 322 may include a fuse or switch that interrupts a conduction path between the first energy storage component 324 and the therapy circuit 314, the communications component 312, the controller 306, and/or the oscillator 310. In embodiments, the deactivation element 322 may include a parasitic circuit that further depletes the first energy storage component 324 such as, for example, a crowbar mechanism. A crowbar mechanism may include any number of different types of circuits configured to drain energy from the first energy storage component 324, thereby preventing delivery of energy from the first energy storage component 324 to any other component.

FIGS. 13 and 14 are schematic circuit diagrams depicting illustrative examples of crowbar mechanisms that may, in embodiments, be utilized as a deactivation element 322. FIG. 13 depicts a bipolar circuit arrangement in which a power source 1302 (e.g., a battery) provides electrical power (e.g., via current) to operational circuitry 1304 (e.g., the operational circuitry 304 depicted in FIG. 3). A crowbar mechanism 1306 is disposed between the power source 1302 and the operational circuitry 1304 and may be utilized as a deactivation element (e.g., the deactivation element 322 depicted in FIG. 3) to prevent power from being delivered to the operational circuitry 1304. A trigger connection 1308 is used to provide a trigger signal (e.g., a deactivation signal) to a first (NPN) transistor T1. The trigger signal activates T1, which causes a second (PNP) transistor T2 to activate, thereby draining power from the power source 1302. The crowbar mechanism 1306 may be, or include, a traditional silicon-controlled rectifier (SCR), discrete transistors T1 and T2, or the like. The resistor R1, illustrated in FIG. 13, may be selected to allow rapid depletion of the power source 1302 without allowing depletion that is so rapid that it causes excessive heat. Additionally, R1 may be selected so that the emitter of T2 does not drop to a voltage so low as to prevent T1 and T2 from remaining activated. FIG. 14 depicts a circuit arrangement in which a power source 1402 provides electrical power (e.g., via voltage) to operational circuitry 1404. A crowbar mechanism 1406 is disposed between the power source 1402 and the operational circuitry 1404 and may be utilized as a deactivation element (e.g., the deactivation element 322 depicted in FIG. 3) to prevent power from being delivered to the operational circuitry 1404. The crowbar mechanism 1406 similar to that of FIG. 13; however, in FIGS. 14, T1 and T2 are metal-oxide-semiconductor field-effect transistors (MOSFETs).

Returning to FIG. 3, the IMD 300 may include a rechargeable power source 320 such as, for example, a rechargeable battery. In such implementations, the IMD 300 may be configured to be partially or completely disabled reversibly and then reactivated after the power source 320 has been recharged. To facilitate returning to a particular operational state upon reactivation, the controller 306 may be configured to save one or more operational parameters associated with the IMD 300, which may be accessed upon reactivation. The one or more operational parameters may be stored in the memory 308. The memory 308 may include one or more memory elements such as, for example, a non-volatile memory element, an active memory element, and/or the like. In embodiments, the controller 306 may be configured to store only an indication of an EOL state associated with the IMD 300, while in other embodiments, the controller 306 may be configured to store a number of operational parameters.

Non-volatile memory may be used, for example, to store information even when IMD 300 is completely disabled (e.g., energy is prevented from being delivered to every component of the IMD 300). Active memory elements may be used to store information when the power source 320 maintains an ability to provide some energy during the EOL state of the IMD 300. For example, the first or second energy storage component 324,326 may include enough stored energy to provide to the memory 308. In embodiments, the memory 308 may be an active storage element configured to store an indication of an EOL state of the IMD 300. The indication may include a single bit or multiple bits. In the case of a single bit (or a small number of bits), the memory 308 may include a latch or system of latches. Other techniques for maintaining information associated with an EOL state are contemplated within the scope of embodiments of the invention. For example, in embodiments, upon detecting an EOL condition, the power manager 316 may be configured to cause the IMD 300 to transfer data (e.g., operational parameters, indications of the EOL condition, etc.) to another IMD 300, a control device, an external programmer and/or the like.

FIG. 4 is a flow diagram depicting an illustrative method 400 of managing an end-of-life (EOL) state of an IMD, in accordance with embodiments of the invention. The IMD may be, or include, the IMD 102 depicted in FIG. 1, the IMD 200 depicted in FIG. 2, and/or the like. In embodiments, the IMD may be a leadless cardiac pacing seed. As shown in FIG. 4, the illustrative method 400 includes detecting an end-of-life (EOL) condition of the IMD (block 402) and, in response, storing an indication of the EOL condition in a memory (block 404). The method 400 also includes configuring a power-up procedure of the IMD such that, when a future activation of the IMD is attempted, the controller first reads the memory containing the indication of the EOL condition (block 406). As depicted in FIG. 4, the IMD is disabled (e.g., by preventing power from being delivered from a power source to one or more components of the operational circuitry of the IMD) (block 408). At some point later, the IMD receives an instruction to power up (e.g., an activation signal) (block 410) and, in response, reads the indication of the EOL state from the memory (block 412). Upon discovering that the IMD has been placed in the EOL state, the controller terminates the power-up procedure (block 414).

FIG. 5 is another flow diagram depicting an illustrative method 500 of managing an EOL state of an IMD, in accordance with embodiments of the invention. According to embodiments, the illustrative method 500 includes detecting an EOL condition of the IMD (block 502) and, in response, storing a set of parameters in a memory (block 504). The method 500 also includes configuring a power-up procedure such that, when a future activation of the IMD is attempted, the controller reads the parameters from the memory (block 506). The IMD is disabled (e.g., by preventing power from being delivered from a power source to one or more components of the operational circuitry of the IMD) (block 508). At some point later, the IMD receives an instruction to power up (block 510) and, in response, reads the stored set of parameters from the memory (block 512). As shown, the device configures itself for operation based on the stored parameters (block 514).

As described above, embodiments of the invention include a deactivation element that facilitates deactivating one or more components of an IMD. The deactivation element may, in embodiments, be configured to selectively disable certain components of an IMD, while allowing other

components to remain active. In embodiments, the deactivation element may selectively disable components by preventing power from being delivered, by the power source, to the selected components. This may be accomplished by using a deactivation element that includes, for example, a number of switches, latches, gates, and/or the like.

FIG. 6 is a schematic block diagram depicting an illustrative IMD 600 having a deactivation element 602 capable of selectively disabling components of the IMD 600, in accordance with embodiments of the invention. The IMD 600 may include any number of different types of IMDs such as for example, implantable sensors, implantable stimulators (e.g., leadless cardiac pacing seeds), implantable control devices, and/or the like. As shown in FIG. 6, the deactivation element 602 is electrically coupled to a power source 604 and provides selectable current paths to a controller 606, a therapy circuit 608, a sensor circuit 610, a memory 612, an oscillator 614, and a communications component 616. A power manager 618 may be configured to monitor the power source 604 and/or one or more other components to detect an end-of-life (EOL) condition. In the illustrated embodiment, the power manager 618 monitors components such as the therapy circuit 608, the sensor circuit 610, and the communications component 616 by accessing information from the controller 606 corresponding to the operation of those components. In embodiments, the power manager 618 may include a direct connection to the components that it monitors.

The illustrative IMD 600 shown in FIG. 6 is not intended to suggest any limitation as to the scope of use or functionality of embodiments of the invention disclosed throughout this document. Neither should the illustrative IMD 600 be interpreted as having any dependency or requirement related to any single component or combination of components illustrated therein. For example, in embodiments, the illustrative IMD 600 may include additional components such as, for example, additional sensor circuits (not illustrated). Additionally, any one or more of the components depicted in FIG. 6 can be, in embodiments, integrated with various ones of the other components depicted therein (and/or components not illustrated). Any number of other components or combinations of components can be integrated with the illustrative IMD 600 depicted in FIG. 6, all of which are considered to be within the scope of this disclosure.

In an example embodiment, the power manager 618 may monitor the therapy circuit 608 and detect an EOL condition. The EOL condition may include, for example, a condition in which the therapy circuit 608 is delivering erratic or otherwise unexpected therapy. Upon detecting the EOL condition, the power manager 618 may send a signal to the deactivation element 602 to cause the deactivation element 602 to prevent power from being delivered from the power source 604 to the therapy circuit 608. The deactivation element 602 may continue to allow power to flow, however, to any number of the other components of the IMD 600. As the power source 604 continues to deplete, the power manager 618 may detect another EOL condition by detecting erratic or otherwise unexpected behavior by the communications component 616. Upon detecting the EOL condition, the power manager 618 may send a signal to the deactivation element 602 to cause the deactivation element 602 to prevent power from being delivered from the power source 604 to the communications component 616.

In embodiments, the deactivation element may selectively disable components by logically disabling the selected components. This may be accomplished by using a deactivation element that includes, for example, isolated logic circuits,

sets of instructions that may be executed by the processor, and/or the like. In aspects of this implementation, for example, all of the components of the IMD **600** depicted in FIG. **6** may be communicatively coupled to the controller, which executes the deactivation element **602** to logically disable selected components.

FIG. **7** is a schematic block diagram depicting an illustrative IMD **700** having a deactivation element **702** capable of selectively disabling components of the IMD **700**, in accordance with embodiments of the invention. The IMD **700** may include any number of different types of IMDs such as for example, implantable sensors, implantable stimulators (e.g., leadless cardiac pacing seeds), implantable control devices, and/or the like. As shown in FIG. **7**, the deactivation element **702** is a logical module executable by a controller **704**. For example, the deactivation element **702** may include a set of computer-readable instructions that are stored in a memory **706** and that, when accessed from the memory **706** and executed by the controller **704**, facilitate logically disabling any one or more components of the IMD **700**.

As shown in FIG. **7**, a power source **708** (e.g., a battery) provides power to the controller **704**, a therapy circuit **710**, a sensor circuit **712**, the memory **706**, an oscillator **714**, and a communications component **716**. A power manager **718** may be configured to monitor the power source **708** and/or one or more other components to detect an end-of-life (EOL) condition. As shown in FIG. **7**, the therapy circuit **710** is coupled to an electrode **720** and is configured to cause electrical pacing energy to be discharged from the electrode **720**. Similarly, the sensor circuit **712** is coupled to a sensor **722**, which, in embodiments, may be an electrode, a pressure sensor, and optical sensor and/or the like. In embodiments, the therapy circuit **710** may be coupled to more than one electrode **720**. In the illustrated embodiment, the power manager **718** monitors components such as the therapy circuit **710**, the sensor circuit **712**, and the communications component **716** by accessing information from the controller **704** corresponding to the operation of those components. In embodiments, the power manager **718** may include a direct connection to the components that it monitors.

The illustrative IMD **700** shown in FIG. **7** is not intended to suggest any limitation as to the scope of use or functionality of embodiments of the invention disclosed throughout this document. Neither should the illustrative IMD **700** be interpreted as having any dependency or requirement related to any single component or combination of components illustrated therein. For example, in embodiments, the illustrative IMD **700** may include additional components such as, for example, additional sensor circuits (not illustrated). Additionally, any one or more of the components depicted in FIG. **7** can be, in embodiments, integrated with various ones of the other components depicted therein (and/or components not illustrated). Any number of other components or combinations of components can be integrated with the illustrative IMD **700** depicted in FIG. **6**, all of which are considered to be within the scope of this disclosure.

In an example embodiment, the power manager **718** may monitor the therapy circuit **710** and detect an EOL condition. The EOL condition may include, for example, a condition in which the therapy circuit **710** is delivering erratic or otherwise unexpected therapy. Upon detecting the EOL condition, the power manager **718** may send a signal to the deactivation element **702** to cause the deactivation element **702** to prevent power from being delivered from the power source **708** to the therapy circuit **710**. The deactivation element **702** may continue to allow power to flow, however, to any number of the other components of the IMD **700**. As

the power source **702** continues to deplete, the power manager **718** may detect another EOL condition by detecting erratic or otherwise unexpected behavior by the communications component **716**.

As shown in FIG. **7**, the communications component **716** includes a transceiver **724** and an antenna **726**. According to embodiments, the communications component **716** may include, instead of a transceiver, a transmitter, a receiver, or both. An EOL condition may be one in which the transceiver **724** (or transmitter) is not receiving sufficient power to accurately modulate an outgoing signal, thereby causing errors and/or gaps in transmitted communication. Similarly, an EOL condition may be one in which the transceiver **724** (or receiver) is not receiving enough power to accurately demodulate an incoming signal, thereby causing errors and/or gaps in received communication. Upon detecting the EOL condition, the power manager **718** may send a signal to the deactivation element **702** to cause the deactivation element **702** to prevent power from being delivered from the power source **708** to the communications component **716**.

In embodiments, a power manager (e.g., the power manager **618** depicted in FIG. **6** or the power manager **718** depicted in FIG. **7**) may be configured, as in the examples above, to selectively disable components of the IMD as EOL conditions are detected. In this manner, embodiments facilitate disabling certain functions of an IMD with minimal disruption to other functions. Additionally, in embodiments, sets of components (e.g., input circuits, output circuits, etc.) may be selectively disabled in stages, either electronically or logically. Disabling the IMD in stages may also facilitate allowing enough time for information to be stored, transmitted, or received. Various algorithms, processes, protocols, and the like may be used to implement embodiments of a staged deactivation. FIG. **8** illustrates an example of such a process.

FIG. **8** is a flow diagram depicting an illustrative method **800** of deactivating an IMD in accordance with embodiments of the invention. In the illustrated example, the IMD may be, for example, a leadless pacing seed that includes at least a therapy circuit, a sensor circuit, and a communications component. As shown in FIG. **8**, the illustrative method **800** includes detecting an end-of-life (EOL) condition (block **802**). In embodiments, a power manager (e.g., the power manager **618** depicted in FIG. **6** or the power manager **718** depicted in FIG. **7**) may be configured to detect an EOL condition associated with the IMD by monitoring the power source or one or more components that consume power from the power source. Monitoring the power source, in embodiments, may include one or more mechanisms and/or processes for monitoring power levels that are stored in, and/or are outputted from, the power source. Monitoring other components, in embodiments, may include one or more mechanisms and/or processes for monitoring the functionality of those components to identify erratic, unreliable, or otherwise unexpected behavior.

Embodiments of the illustrative method **800** further include preventing power delivery to the therapy circuit (block **804**). In response to detecting the EOL condition, the power manager may provide a signal to a deactivation element (e.g., the deactivation element **602** depicted in FIG. **6** or the deactivation element **702** depicted in FIG. **7**) that causes the deactivation element to prevent power from flowing from the power source to the therapy circuit. In the illustrative method **800**, while continuing to monitor components of the IMD, the power manager detects an insufficient power condition (e.g., another EOL condition) associated with the communications component (**806**). For

example, the power manager may detect that the communications component is communicating a number of errors that exceed a threshold, is transmitting random packets, or the like. In response to detecting the EOL condition, the power manager may send a signal to the deactivation element to cause it to prevent power delivery to the communications component (block **808**). During further monitoring, the power manager may detect an insufficient power condition for the sensor circuit (block **810**) and, in response, may cause the deactivation element to prevent power delivery to the sensor circuit (block **812**). In embodiments, the order in which elements are deactivated may be different than the order described above. For example, in embodiments, the therapy circuit might be disabled last in order to provide therapy to the patient for as long as possible.

FIG. **9** depicts another illustrative method **900** of deactivating an IMD in accordance with embodiments of the invention. As shown in FIG. **9**, the illustrative method **900** includes determining that an end-of-life (EOL) condition of the IMD is nearing (block **902**) and setting an EOL state trigger (block **904**). According to embodiments, the EOL state trigger may include a condition or conditions that, when satisfied, result in the deactivation element deactivating the IMD. The condition may include passage of a certain amount of time, a predetermined energy level in the power source, an occurrence of a certain action (e.g., receipt of a signal from another IMD, a control device, or an external device), a non-occurrence of a certain action within a certain amount of time, and/or the like. In the illustrative method **900**, the EOL state trigger is detected (block **906**) and, in response, the IMD is disabled (block **908**).

As indicated previously, embodiments of the invention include an IMD such as a leadless pacing seed that operates within a system having one or more additional leadless pacing seeds. Embodiments include modifying a therapy program and/or communication structure of the remaining seeds when a first seed reaches an end-of-life condition. In this manner, the system mitigates effects of the loss of the use of the first seed. FIG. **10** is a block schematic diagram depicting illustrative operations of a leadless pacing system **1000** configured to mitigate for the loss of a pacing seed, in accordance with embodiments of the invention. According to various embodiments, the system **1000** depicted in FIG. **10** may include a system for providing cardiac resynchronization therapy (CRT), defibrillation therapy, and/or the like. Although the system **1000** is described in the context of a cardiac stimulation system, the system **1000** may represent any number of different types of systems such as, for example, a neurostimulation system, an electrocardiograph sensing system, and/or the like.

The illustrative system **1000** includes a first leadless cardiac pacing (LCP) seed **1002**, a second LCP seed **1004**, and a control device **1006**. The first and second LCP seeds **1002** and **1004** may be any number of different types of leadless pacing seeds. In embodiments, the seeds **1002** and **1004** may be similar to the IMDs described previously such as, for example, the IMD **102** depicted in FIG. **1**, the IMD **200** depicted in FIG. **2**, and/or the IMD **300** depicted in FIG. **3**. The control device **1006** may be similar to the co-implanted device **202** depicted in FIG. **2** and may be, or include, a pacemaker module, a subcutaneous implantable cardioverter defibrillator (S-ICD), and/or the like. The illustrated system **1000** also includes an external device **1008** which may, in embodiments, be an external programmer, a magnet, an interrogation device, and/or the like.

The external device **1008** may be used to communicate with the implantable control device **1006**. For example, the

external device **1008** may be used to program such parameters as the timing of stimulation pulses in relation to certain sensed electrical activity of the heart, the energy level of stimulation pulses, the duration of stimulation pulses (that is, pulse width), and/or the like. Additional information such as locations of seeds **1002** and **1004** within heart chambers may be programmed, as well as pacing requirements involving one or more of the distributed seeds **1002** and **1004**. The external device **1008** may include an antenna to communicate with the control device **1006**, using, for example, RF signals. The implantable control device **1006** may accordingly be equipped to communicate with the external device **1008** using, for example, RF signals. Similarly, the control device **1006** may transmit information, such as sensed cardiac patient information, system status information, warning information, and the like, to an external computing device. Physicians or care providers may then monitor the information and make changes as appropriate.

According to embodiments of the system **1000** illustrated in FIG. **10**, a dual-chamber therapy may be provided using two LCP seeds **1002** and **1004**, in which case each seed **1002** and **1004** may be reliant on the other's behavior. That is, for example, a first seed **1002** may be configured as a "slave" and may be configured to provide therapy in response to a second seed **1004**, configured as a "master," providing therapy. In other embodiments, the two LCP seeds **1002** and **1004** may be peer devices in which neither is a master or a slave, though aspects of the operation of each may depend upon aspects of the operation of the other. In embodiments, the synchronization between the first and second seeds **1002** and **1004** may be provided by communications between the two seeds **1002** and **1004** themselves, by a control device **1008**, and/or a combination of these. In other embodiments, a number of additional LCP seeds may be utilized for providing any number of different types of therapy such as cardiac resynchronization therapy, anti-tachycardia pacing therapy, neural stimulation therapy, and/or the like.

In embodiments, each of the first and second LCP seeds **1002** and **1004**, operating according to a first operational state, may be monitored to detect an end-of-life (EOL) condition associated therewith. For example, each LCP seed **1002** and **1004** may include a power manager (e.g., the power manager **216** depicted in FIG. **2**) that monitors a battery and/or one or more components (e.g., operational circuitry) of the seed **1002**, **1004**. In embodiments, the control device **1006** and/or the external device **1008** may monitor the LCP seeds **1002** and **1004** to detect EOL conditions. When one of the LCP seeds **1002** or **1004** is placed into an EOL state, the other of the seeds **1002** or **1004** may be configured, as described herein, to adjust its therapy and/or communications so as to compensate for the loss of the functionality of the seed **1002** or **1004** that is in an EOL state. In embodiments, the control device **1006** and/or the external device **1008** may be used to facilitate modifying the therapy and/or communications. In other embodiments, the seeds **1002** and **1004** themselves may be configured to adjust operations to compensate for the loss of the other seed or seeds.

FIG. **10** also schematically illustrates an example of a compensation procedure that may be implemented according to embodiments of the invention. As shown in FIG. **10**, when an EOL condition associated with the first LCP seed **1002** is detected, a notification signal **1010** may be transmitted to the control device **1006** that indicates that the EOL condition has been detected. The LCP seed **1002** may also transmit information **1012** to the control device **1006** to be used in modifying therapy programs and/or communication

structures. Accordingly, the information **1012** may include, for example, operational parameters, communications protocols, physiological parameters sensed by the LCP **1002**, and/or the like.

Upon receiving the notification signal **1010** and the information **1012**, the control device **1006** may, for example, implement a procedure for resynchronizing therapy and/or communication structures. In embodiments, the control device **1006** may include predetermined modified therapy programs and/or communication structures, calculation modules for determining modified therapy programs and/or communication structures, and/or combinations of these. In the illustrated example, the control device **1006** may determine a modified therapy program that is configured to facilitate providing therapy using only the second LCP seed **1004** and a modified communication structure that facilitates communications between the control device **1006** and only the second LCP seed **1004**. In other embodiments, the system **1000** may include a number of additional LCP seeds and the control device **1006** may, for example, be configured to determine a modified therapy program that redistributes therapy duties among the remaining seeds.

The control device **1006** may provide the modified therapy program and/or communication structure via a communication **1014** to the second LCP seed **1004**. The LCP seed **1004** may store the modified therapy program and/or communication structure and configure its operational circuitry to implement the modified program/structure, thereby implementing a second operational state. When the second LCP seed **1004** has finished configuring itself to operate according to the second operational state, the second seed **1004** may provide a confirmation signal **1016** to the control device **1006** to indicate to the control device that the second seed **1004** is prepared to operate in the absence of operation of the first LCP seed **1002**.

Having received the confirmation signal **1014**, the control device **1006** may provide an activation signal **1018** to the second LCP seed **1004** and a deactivation signal **1020** to the first LCP seed **1002**. In embodiments, the activation signal **1018** and the deactivation signal **1020** may be provided substantially simultaneously (e.g., in parallel), and, in embodiments, the two signals **1018** and **1020** may be provided sequentially (e.g., in series). According to embodiments, the activation signal **1018** and the deactivation signal **1020** may actually be communicated as a single broadcast communication. In aspects of such implementations, the control device **1006** may provide instructions to the first LCP seed **1002** that configure the first LCP seed **1002** to interpret the broadcast signal as a deactivation signal, and instructions to the second LCP seed **1004** that configure the second LCP seed **1004** to interpret the broadcast signal as an activation signal.

According to embodiments, the control device **1006** may provide any number of various types of information to the external device **1008** regarding the state of the system **1000**. For example, in an embodiment, the control device **1006** may provide an indication to the external device **1008** that the control device **1006** has received the confirmation signal **1014** from the second LCP seed **1004**. The external device **1008** may provide instructions to the control device **1006** that cause the control device **1006** to be configured to wait to receive an implementation signal from the external device **1008** before sending the activation signal **1018** and deactivation signal **1020**. In this manner, the system **1000** may be prepared to transition to a system state in which the first LCP seed **1002** is disabled and the second LCP seed **1004** operates according to the second operational state. When the

implementation signal is received from the external device **1008**, the control device **1006** may provide the activation signal **1018** and the deactivation signal **1020** to the second LCP seed **1004** and the first LCP seed **1002**, respectively. In embodiments, the implementation signal may be triggered by satisfaction of a condition, a manual input provided by a clinician, or the like.

Upon receiving the activation signal **1018**, the second LCP seed **1004** may process the signal **1018** and, in response, implement the second operational state. In this manner, the second LCP seed **1004** may begin providing therapy according to the modified therapy program and may begin communicating with the control device **1006** according to the modified communication structure. Upon receiving the deactivation signal **1020**, the first LCP seed **1002** may process the signal **1020**, which may cause a deactivation element to disable the first LCP seed **1002**. As discussed above, the deactivation element of the first LCP seed **1002** may disable the first LCP seed **1002** by logically disabling one or more components thereof (e.g., a therapy circuit, a communications component, an oscillator, etc.), preventing power from being delivered to one or more components (e.g., operational circuitry) thereof, blowing a fuse, crow-barring the power source, and/or the like. For example, in embodiments, the deactivation element of the first LCP seed **1002** may initially disable the therapy circuit, while leaving the communications component operational so that the first LCP seed **1002** can provide a confirmation of deactivation (not shown) to the control device **1006**. In other embodiments, the deactivation element may disable the therapy circuit and the communications component.

In embodiments, the first and second LCP seeds **1002** and **1004** deliver pacing therapy in a dual-chamber pacing (DDD) mode in which the seed **1002** is implanted such that at least one of its electrodes contacts atrial tissue and in which the seed **1004** is implanted such that at least one of its electrodes contacts ventricular tissue. Upon the depletion of, for example, the power source of the seed **1002**, the seed **1004** alters its therapy from pacing in a DDD mode to pacing in a ventricular pacing (VVI) mode. In another embodiment, the first and second LCP seeds **1002** and **1004** deliver cardiac resynchronization therapy in which the seed **1002** is implanted such that at least one of its electrodes contacts left ventricular tissue and in which the seed **1004** is implanted such that at least one of its electrodes contacts right ventricular tissue. Upon depletion of, for example, the power source of the seed **1002**, the seed **1004** alters its therapy from cardiac resynchronization therapy to bradycardia therapy and paces in a right ventricular-only VVI mode.

FIG. **11** is a flow diagram depicting an illustrative method **1100** of deactivating a first IMD that is being replaced by a second IMD, in accordance with embodiments of the invention. As shown in FIG. **11**, the illustrative method **1100** includes detecting an end-of-life condition (EOL) of a first device (block **1102**) and, in response, activating a second device (block **1104**). In embodiments, the second device may be implanted before an EOL condition of the first device is anticipated and may be initially in a dormant state. The dormant state may, for example, be characterized by a state in which the second device has only enough components activated so that the second device can receive a signal from the first device, from an external device, and/or the like.

Accordingly, the second device may be activated by a signal sent from the first device to the second device. Activation of the second device may place the second device in a stand-by state, in which the second device can receive

information and/or additional instructional signals from the first device, a control device, an external device, and/or the like. In embodiments, the second device may be activated by a signal sent from the control device or an external device.

In response to detecting the EOL condition of the first device, the first device transfers information to the second device (block **1106**). In embodiments, the information transferred to the second device may include operational parameters such as therapy parameters, physiological parameters, and the like. The method **1100** further includes configuring the second device to replace the therapy provided by the first device (block **1108**). For example, the second device may process the information received from the first device to generate a set of operational parameters that may be used to implement an operational state in which the second device provides therapy in a manner that replaces the therapy provided by the first device.

Once configured, the second device is activated, to begin operation according to the operational state (block **1110**) and the first device is disabled (block **1112**). In embodiments, the second device may be activated automatically upon receiving and processing the information from the first device. In other embodiments, the second device may be activated upon receiving an activation signal from a control device and/or an external device. Similarly, the first device may be disabled automatically after sending the information to the second device or upon receiving a confirmation signal from the second device, a control device, and/or an external device.

FIG. **12** is a flow diagram depicting an illustrative method **1200** of deactivating a leadless pacing seed that is part of a leadless pacing system, in accordance with embodiments of the invention. As shown in FIG. **12**, the illustrative method **1200** includes detecting an end-of-life (EOL) condition of a first pacing seed (block **1202**) and, in response, sending a signal to a control device that indicates the EOL condition of the first pacing seed (block **1204**). In embodiments, the first pacing seed includes a power manager that monitors the power source and/or one or more components (e.g., operational circuitry) of the seed to detect an EOL condition. Upon detecting the EOL condition, the power manager may cause a controller to communicate, via a communications component, a signal to a control device.

As illustrated in FIG. **12**, the control device determines a modified therapy program based on an anticipated loss of the first pacing seed (block **1206**) and communicates the modified therapy program to a second pacing seed (block **1208**). According to various embodiments, the control device includes a processor that executes a set of routines to determine the modified therapy program. In embodiments, the control device may include a memory that stores a set of modified therapy program, and the control device may select the appropriate program based on an identification of the particular seed that has reached an EOL condition. A modified therapy program may include different sets of operational parameters for each of a number of seeds, as described above with respect to FIG. **11**, and the control device may communicate each set of operational parameters to the appropriate seed.

In the illustrative method **1200**, the control device also determines a modified seed communication structure based on the anticipated loss of the first pacing seed (block **1210**) and communicates the modified seed communication structure to the second pacing seed (block **1212**). This modified communication structure may specify communication flows, protocols, and/or the like.

In embodiments, prior to the anticipated loss of the first pacing seed (prior to block **1202**) the second pacing seed operates in a low-power communication mode. The low-power communication mode limits the energy used for communication before the second seed is delivering therapy. In order to achieve the lower power in this mode, the second seed's communication components may, for example, operate at a lower receive and/or transmit bit rate. After an EOL condition has been detected, the communication structure of the second seed may be modified to a higher-power mode that can support the communication requirements of the second seed while it provides therapy.

As shown in FIG. **12**, the control device sends a signal to the second seed to cause the second seed to implement the modified therapy program (block **1214**). In embodiments, the system may include a number of additional seeds to which the control device has provided modified therapy programs and communication structures and the control device may send each of these seeds a signal to cause implementation of the programs and structures. In embodiments, for example, the control device may broadcast a signal that, when received by any of the seeds, causes the seed to implement modified therapy programs and/or communication structures. The seeds may be configured to respond to the control device with a verification signal, indicating that the modified therapy program and communication structure have been implemented. Upon receiving the verification that the modified therapy program has been implemented (block **1216**), the control device sends a signal to the first pacing seed to cause the first pacing seed to disable (block **1218**). In embodiments, for example, the signal causes a deactivation element (e.g., as described herein with reference to FIGS. **1-7**) to disable one or more components of the seed (e.g., a therapy circuit, a communications component, an oscillator, and/or the like). In embodiments, upon receiving the signal to disable therapy (block **1218**) the first pacing seed sends an acknowledge signal back to the control device. After transmission of the acknowledge signal, the first pacing seed disables itself as described herein with reference to FIGS. **1-7**.

While the invention is amenable to various modifications and alternative forms, specific embodiments have been shown by way of example in the drawings and are described in detail below. The intention, however, is not to limit the invention to the particular embodiments described. On the contrary, the invention is intended to cover all modifications, equivalents, and alternatives falling within the scope of the invention as defined by the appended claims.

We claim:

1. An implantable medical device comprising:
 - operational circuitry, wherein the operational circuitry comprises at least one of a therapy circuit and a sensor circuit;
 - a communications module;
 - a power source configured to deliver energy to the operational circuitry;
 - a deactivation element configured to at least partially disable the operational circuitry by interrupting delivery of energy from the power source to the operational circuitry;
 - a power manager configured to detect, based on a behavior of at least the communications module, an end-of-life condition of the power source and, in response to detecting the end-of-life condition, cause the deactivation element to at least partially reversibly disable the operational circuitry; and

21

a controller configured to store, in a memory component and in response to the power manager detecting the end-of-life condition, an indication of an end-of-life state of the implantable medical device.

2. The implantable medical device of claim 1, wherein the implantable medical device comprises a leadless cardiac pacing seed. 5

3. The implantable medical device of claim 1, wherein the operational circuitry comprises the therapy circuit.

4. The implantable medical device of claim 3, wherein the deactivation element is configured to prevent energy from being delivered to the therapy circuit. 10

5. The implantable medical device of claim 1, wherein the memory component comprises an active storage element.

6. The implantable medical device of claim 5, wherein the power manager is configured to allow energy to be delivered to the memory component during the end-of-life state. 15

7. The implantable medical device of claim 1, wherein the memory component comprises a non-volatile memory element. 20

8. The implantable medical device of claim 7, wherein the memory component is further configured to store a plurality of operational parameters during the end-of-life state.

9. The implantable medical device of claim 8, wherein the power source comprises a rechargeable battery. 25

10. The implantable medical device of claim 9, wherein the controller is configured to access the plurality of operational parameters in response to receiving an activation signal.

11. The implantable medical device of claim 10, wherein the controller is configured to restore the device to its pre-end-of-life state using the operational parameters. 30

12. A leadless cardiac pacing seed comprising:
a therapy circuit;
a communications module;
a power source configured to deliver energy to the therapy circuit and the communications module; 35

22

a deactivation element configured to disable at least one of the therapy circuit and the communications module by reversibly interrupting delivery of energy from the power source to the therapy circuit or the communications module;

a power manager configured to detect, based on a behavior of at least the communications module, an end-of-life condition of the seed and, in response to detecting the end-of-life condition, cause the deactivation element to reversibly disable at least one of the therapy circuit and the communications module; and

a controller configured to store, in a memory component and in response to the power manager detecting the end-of-life condition, an indication of an end-of-life state of the implantable medical device.

13. The leadless cardiac pacing seed of claim 12, wherein the memory component comprises an active storage element.

14. The leadless cardiac pacing seed of claim 13, wherein the power manager is configured to allow energy to be delivered to the memory component during the end-of-life state.

15. The leadless cardiac pacing seed of claim 12, wherein the memory component comprises a non-volatile memory element. 25

16. The leadless cardiac pacing seed of claim 15, wherein the memory component is further configured to store a plurality of operational parameters during the end-of-life state, and wherein the controller is configured to access the plurality of operational parameters in response to receiving an activation signal.

17. The implantable medical device of claim 16, wherein the controller is configured to restore the device to its pre-end-of-life state using the operational parameters. 35
