(57) **ABSTRACT**

A method of facilitating customization of a software-implemented business process includes storing, within a mobile computing device, a subscription list of entities. The subscription list is defined by subscription metadata. Customized data is received. The customized data corresponds to the entities identified in the subscription list. The received

METADATA DRIVEN CUSTOMIZATION OF A COMPUTER APPLICATION

CROSS-REFERENCE TO RELATED APPLICATION

The present application is a continuation of and claims priority of U.S. patent application Ser. No. 12/984,686, filed Jan. 5, 2011, which is based on and claims the benefit of U.S. patent application Ser. No. 10/760,099, filed Jan. 16, 2004, now U.S. Pat. No. 7,890,544, issued Feb. 15, 2011. The contents of these applications are hereby incorporated by reference in their entirety.

BACKGROUND

The present disclosure generally relates to customization of a software-implemented business process and, more particularly, to a method of customizing a software-implemented business process on a mobile computing device without having to modify the source code.

One approach to designing and marketing computer software-related products is to focus on horizontal functionality such that the product is broadly applicable across large industry segments, and across many different countries. Such a system may also desirably promote an aftermarket to meet the unique needs of specific vertical target markets and specific companies. Similarly, the product may desirably promote a customer's ability to change or customize the product to their individual needs.

If the product cannot be extended to meet the unique needs of a customer, it essentially requires a customer to change its business to match the software which the customer has just purchased. Of course, these types of systems are resisted by customers, since changes to business activities can be costly and time consuming.

There are a number of different techniques which have been conventionally used in order to enable a system to be customized. Such conventional techniques include, for example, source code modification. This technique entails providing customers with copies of the source code for the product. It thus allows a well trained practitioner to change significant amounts of content, and those changes can be made to look as if they are part of the product, because in effect, they are part of the modified source code product.

However, source code modification carries with it significant drawbacks. For example, source code modification costs a significant amount of money prior to using the product, because the user or customer must often hire expensive consultants and developers who have been specifically trained in the nuances of how the product is built. The user must then endure the risk of estimating a problem, which is a very difficult and imprecise task. Even if these problems can be overcome and persevered, the result is modified source code. When the manufacturer of the original source code ships additional software, such as bug fixes, updates, and new versions, the customer is either forced to again hire talented engineers or developers (and hopefully the same ones who made the original modifications), in order to merge those modifications into the new source code shipped by the manufacturer, and to resolve issues, one-by-one, as they arise in the newly modified source code. Alternatively, the user can simply go without the bug fixes and new features that may benefit the user's business.

In addition, source code modification makes it extremely difficult to simply purchase add-on modules "off the shelf" from multiple different vendors, because each of those

vendors will likely have to modify the source code as well to accommodate their specific off the shelf modules. Consequently, not only must the manufacturer ship the source code of the base product, but each add-on vendor must ship their source as well. The user must then conduct some sort of adhoc merge process or synthesize a single product out of these random sets of source code. Of course, this results in a brittle set of code that is virtually guaranteed to have problems with upgrades or when any one of the vendors ships a bug fix.

Source code modification also suffers from the problem that only one organization in the world (the specific developers or engineers who modified the source code) knows how the modified source code product was built. Therefore, it is difficult, if not impossible, to achieve economies of scale and product support for any of the products running at the customer site.

The problems with source code modification increase significantly when, even within a single customer, there exists a diverse set of users with a diverse set of needs and preferences. Every time one of those users changes the product through the source code modification strategy in order to accommodate their particular needs, the customer employing those users, in effect, ends up with a new source code base. In other words, the customer does not only have a single custom code base, but it may actually have many custom code bases, depending upon how many specific users or departments within the customer have modified the code base. Again, each time a bug fix is published or a change is made to a customization that applies to all users, the customer must go through some sort of merge process with all other copies of the source which have been made.

This is only a partial list of the many problems associated with source code modification techniques. These problems can result in a great deal of difficulty for the management of the customer, and the employees themselves.

Another technique which enables some limited modification of a computer program that is based on objects includes the addition of user fields which can be defined by the user. In other words, each object which is to be "customizable" is initially defined to have one or more user fields which can be defined or used by the user, as the user wishes. While this does allow some type of customization, it does not solve all the problems mentioned above. It also carries with it a large number of its own problems. For example, the naming convention associated with the user fields makes it non-intuitive and difficult to associate the specific uses of those user fields. For instances, the additional user fields are typically named with very general names such as "USER-FIELD.1" to "USERFIELD.N" It is difficult, if not impossible, for the users to remember what each user field has been used for. In addition, the additional user fields do not solve problems associated with multi-vendors or multiple modifications by different organizations. For example, if one vendor or one user assigns the user fields in a first way, but another vendor or user assigns the same user fields in a different way, then there is inconsistency in how the user fields are defined, and the two products associated with the two vendors or users will not work together without even further modification.

Other techniques for customizing have been tried as well. For example, customizations can be made by writing custom event code. Then, by using a one-to-one mapping to the original objection in the source code, the "customized" object can be manipulated when an event occurs on the original object. Another technique previously used is to include "property bags" or name-value pairs. Both of these

techniques also have significant drawbacks and do not remedy the deficiencies associated with source code modification.

It is becoming more common for some business applications, such as customer relationship management applications, to be implemented in mobile computing devices. Such mobile computing devices include personal digital assistants (PDA's), mobile phones, and other mobile computing devices. User's of such systems generally update a database on the mobile computing device through a synching operation with a central database of a server thereby making the data, such as account information, accessible by the user of the mobile computing device. Unfortunately, limitations in the memory capacity of mobile computing devices make it undesirable to perform full uploads of the data contained in the central database, which can be time-consuming as well.

SUMMARY

Embodiments of a method of facilitating customization of a software-implemented business process are disclosed. In one embodiment, a subscription list of entities is stored within a mobile computing device. The subscription list being defined by subscription metadata. Customized data is received. The customized data corresponds to the entities identified in the subscription list. The received customized metadata is stored on the mobile computing device.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram of an environment in which the present invention can be used.

FIG. 2 is a block diagram of an example of a system configured to customize a computer-implemented business process, in accordance with embodiments of the invention.

FIG. 3 illustrates an embodiment of a metadata structure and customizations in accordance with embodiments of the present invention.

FIGS. 4-6 are screen shots illustrating an example of a customization of a system screen in accordance with embodiments of the present invention.

FIG. 7 is a flowchart illustrating a method of customizing a software-implemented business process in accordance with an embodiment of the invention.

FIGS. 8A-8B are examples of graphical user interfaces in accordance with embodiments of the invention.

FIG. 9 is a flowchart illustrating method of customizing a software-implemented business process in accordance with an embodiment of the invention.

DETAILED DESCRIPTION OF ILLUSTRATIVE EMBODIMENTS

The present invention generally relates to customization of a software-implemented business process or application. However, prior to discussing the present invention in greater detail, one embodiment of an illustrative environment in which the present invention can be used will be discussed.

FIG. 1 illustrates an example of a suitable computing system environment 100 on which the invention may be implemented. The computing system environment 100 is only one example of a suitable computing environment and is not intended to suggest any limitation as to the scope of use or functionality of the invention. Neither should the computing environment 100 be interpreted as having any

dependency or requirement relating to any one or combination of components illustrated in the exemplary operating environment 100.

The invention is operational with numerous other general purpose or special purpose computing system environments or configurations. Examples of well known computing systems, environments, and/or configurations that may be suitable for use with the invention include, but are not limited to, personal computers, server computers, hand-held or laptop devices, multiprocessor systems, microprocessor-based systems, set top boxes, programmable consumer electronics, network PCs, minicomputers, mainframe computers, distributed computing environments that include any of the above systems or devices, and the like.

The invention may be described in the general context of computer-executable instructions, such as program modules, being executed by a computer. Generally, program modules include routines, programs, objects, components, data structures, etc. that perform particular tasks or implement particular abstract data types. The invention may also be practiced in distributed computing environments where tasks are performed by remote processing devices that are linked through a communications network. In a distributed computing environment, program modules may be located in both local and remote computer storage media including memory storage devices.

With reference to FIG. 1, an exemplary system for implementing the invention includes a general purpose computing device in the form of a computer 110. Components of computer 110 may include, but are not limited to, a processing unit 120, a system memory 130, and a system bus 121 that couples various system components including the system memory to the processing unit 120. The system bus 121 may be any of several types of bus structures including a memory bus or memory controller, a peripheral bus, and a local bus using any of a variety of bus architectures. By way of example, and not limitation, such architectures include Industry Standard Architecture (ISA) bus, Micro Channel Architecture (MCA) bus, Enhanced ISA (EISA) bus, Video Electronics Standards Association (VESA) local bus, and Peripheral Component Interconnect (PCI) bus also known as Mezzanine bus.

Computer 110 typically includes a variety of computer readable media. Computer readable media can be any available media that can be accessed by computer 110 and includes both volatile and nonvolatile media, removable and non-removable media. By way of example, and not limitation, computer readable media may comprise computer storage media and communication media. Computer storage media includes both volatile and nonvolatile, removable and non-removable media implemented in any method or technology for storage of information such as computer readable instructions, data structures, program modules or other data. Computer storage media includes, but is not limited to, RAM, ROM, EEPROM, flash memory or other memory technology, CD-ROM, digital versatile disks (DVD) or other optical disk storage, magnetic cassettes, magnetic tape, magnetic disk storage or other magnetic storage devices, or any other medium which can be used to store the desired information and which can be accessed by computer 110. Communication media typically embodies computer readable instructions, data structures, program modules or other data in a modulated data signal such as a carrier wave or other transport mechanism and includes any information delivery media. The term "modulated data signal" means a signal that has one or more of its characteristics set or changed in such a manner as to encode information in the

signal. By way of example, and not limitation, communication media includes wired media such as a wired network or direct-wired connection, and wireless media such as acoustic, RF, infrared and other wireless media. Combinations of any of the above should also be included within the scope of computer readable media.

The system memory 130 includes computer storage media in the form of volatile and/or nonvolatile memory such as read only memory (ROM) 131 and random access memory (RAM) 132. A basic input/output system 133 (BIOS), containing the basic routines that help to transfer information between elements within computer 110, such as during start-up, is typically stored in ROM 131. RAM 132 typically contains data and/or program modules that are immediately accessible to and/or presently being operated on by processing unit 120. By way of example, and not limitation, FIG. 1 illustrates operating system 134, application programs 135, other program modules 136, and program data 137.

The computer 110 may also include other removable/non-removable volatile/nonvolatile computer storage media. By way of example only, FIG. 1 illustrates a hard disk drive 141 that reads from or writes to non-removable, nonvolatile magnetic media, a magnetic disk drive 151 that reads from or writes to a removable, nonvolatile magnetic disk 152, and an optical disk drive 155 that reads from or writes to a removable, nonvolatile optical disk 156 such as a CD ROM or other optical media. Other removable/non-removable, volatile/nonvolatile computer storage media that can be used in the exemplary operating environment include, but are not limited to, magnetic tape cassettes, flash memory cards, digital versatile disks, digital video tape, solid state RAM, solid state ROM, and the like. The hard disk drive 141 is typically connected to the system bus 121 through a non-removable memory interface such as interface 140, and magnetic disk drive 151 and optical disk drive 155 are typically connected to the system bus 121 by a removable memory interface, such as interface 150.

The drives and their associated computer storage media discussed above and illustrated in FIG. 1, provide storage of computer readable instructions, data structures, program modules and other data for the computer 110. In FIG. 1, for example, hard disk drive 141 is illustrated as storing operating system 144, application programs 145, other program modules 146, and program data 147. Note that these components can either be the same as or different from operating system 134, application programs 135, other program modules 136, and program data 137. Operating system 144, application programs 145, other program modules 146, and program data 147 are given different numbers here to illustrate that, at a minimum, they are different copies.

A user may enter commands and information into the computer 110 through input devices such as a keyboard 162, a microphone 163, and a pointing device 161, such as a mouse, trackball or touch pad. Other input devices (not shown) may include a joystick, game pad, satellite dish, scanner, or the like. These and other input devices are often connected to the processing unit 120 through a user input interface 160 that is coupled to the system bus, but may be connected by other interface and bus structures, such as a parallel port, game port or a universal serial bus (USB). A monitor 191 or other type of display device is also connected to the system bus 121 via an interface, such as a video interface 190. In addition to the monitor, computers may also include other peripheral output devices such as speakers 197 and printer 196, which may be connected through an output peripheral interface 195.

The computer 110 may operate in a networked environment using logical connections to one or more remote computers, such as a remote computer 180. The remote computer 180 may be a personal computer, a hand-held device, a server, a router, a network PC, a peer device or other common network node, and typically includes many or all of the elements described above relative to the computer 110. The logical connections depicted in FIG. 1 include a local area network (LAN) 171 and a wide area network (WAN) 173, but may also include other networks. Such networking environments are commonplace in offices, enterprise-wide computer networks, intranets and the Internet.

When used in a LAN networking environment, the computer 110 is connected to the LAN 171 through a network interface or adapter 170. When used in a WAN networking environment, the computer 110 typically includes a modem 172 or other means for establishing communications over the WAN 173, such as the Internet. The modem 172, which may be internal or external, may be connected to the system bus 121 via the user-input interface 160, or other appropriate mechanism. In a networked environment, program modules depicted relative to the computer 110, or portions thereof, may be stored in the remote memory storage device. By way of example, and not limitation, FIG. 1 illustrates remote application programs 185 as residing on remote computer 180. It will be appreciated that the network connections shown are exemplary and other means of establishing a communications link between the computers may be used.

One aspect of the method and system of the present invention is generally directed to customizing a software-implemented business process or application that utilizes an object-relational (or entity-relational) data storage system. Such customization is desirable to allow for affordable business applications to be produced that are specific enough to increase business productivity while, at the same time, are general enough to attract a wide customer base.

The method and system of the present invention are particularly useful when used to provide entity customization and filtering for customer relationship management (CRM) applications on mobile computing devices. Such applications are configured to help businesses build profitable customer relationships by allowing, for example, sales and service employees to share information, such as sales leads, customer history, and searchable knowledgebases. For example, a car salesperson may be interested in the mileage of a customer's car, whereas an insurance salesperson would rather know about a customer's age and health history. The present invention provides the tools that are necessary to customize the application to suit the needs of car and insurance salespeople, farmers, and other salespeople.

FIG. 2 is a schematic diagram of an example of a system, designated as 200, in accordance with embodiments of the present invention. System 200 generally includes a central data storage system 202 on server 204 and one or more mobile computing devices 206, each of which include a business application 208 and a mobile data storage system 210.

In accordance with one aspect of the present invention, application 208 is driven by metadata 212 contained in mobile relational database or data store 214, which, in accordance with one embodiment of the invention, is a subset of customized metadata 216 contained in relational database or data store 218 of central data storage system 202. The metadata (212 and 216) generally define the elements of the data structures of the systems 202 and 210 and control how the application 208 operates and displays itself. This allows the applications 208 on mobile computing

devices **206** to be customized, through customization of the metadata **212**, to meet the needs of a vertical industry without requiring modification to the underlying code of the applications **208**.

One advantage to this approach is that the metadata driven applications **208** on mobile computing devices **206** can be customized by an administrator who does understanding how to code using, for example, graphical user interface tools. Additionally, customizations can be easily deployed onto the server **204** as customized metadata **216** and onto the mobile computing devices **206** (e.g., personal digital assistants (PDA's), mobile phones, etc.) as mobile metadata **212** without recompiling the code for application **208**. Furthermore, the applications **208** can be updated through installation of service packs without losing any of the customizations that have been made. As a result, the applications **208** can easily evolve along with the needs of a business without requiring the intervention of the developer of the business application.

The data storage systems **202** and **210** are preferably entity-relational (E-R) storage systems. However, it should be noted that the present invention can be used with other types of data storage systems and, therefore, is not limited to E-R systems. The data storage systems **202** and **210** respectively include a set of entities (or objects) **220** and **222**, which correspond to relational data **224** and **226** stored in the corresponding database or data stores **218** and **214**. Data storage systems **202** and **210** also include data accessing systems **228** and **230**, which respectively provide access to the relational data **224** and **226** by matching the data to the entities **220** and **222** using entity-relational (E-R) maps **232** and **234**. E-R maps **232** and **234** respectively contain mappings between the entities **220** and **222** and the table entries of data **224** and **226** in the corresponding databases **218** and **214**. Data storage systems **202** and **210** can include additional maps, such as a map defining relationships between individual entities **220** and **222**.

Entities **220** and **222** of data storage systems **202** and **210** can be rendered in accordance with metadata **216** and **212**. Accordingly, the metadata **216** and **212** can comprise individual metadata entities, each of which define one of the entities **220** and **222** of the systems **202** and **210**.

As mentioned above, the customized metadata **216** of central system **202** on server **204** is preferably customizable by the administrator or customizer of system **200** and a subset of the customized metadata **216** is provided to the system **210** of the mobile computing device **206** and stored as metadata **212**. Preferably, metadata **212** of mobile computing device **206** defining entities **222** is preferably not customizable by the user of the mobile computing device **206**. As a result, the customized metadata **216** also operates to customize the business application **208** of the mobile computing device **206**, as will be discussed below in greater detail.

The metadata **216** and **212** define basic classes of content for the entities **220** and **222** including data content and user interface content. The data content represents information that the system stores. For example, the data content may include customers, inventor items, orders, etc., each of which is defined by a data field. User interface content includes content that a user sees on a screen or report. It may contain such things as layout information, messages, data field labels, etc. These types of contents, as well as other types, can be customized in accordance with various embodiments of the present invention.

Metadata **216** are customized using customization tool **240** based upon input **242** from an administrator or custom-

izer of system **200**. Customization tool **240** generally provides a graphical user interface that assists the customizer **242** through the process of customizing metadata **216**. Initially, each new metadata entity may consist of a base metadata entity that contains default data and user interface content settings. The user interface of the customization tool **240** preferably allows the customizer to add, delete, and modify the data and user interface content of the base metadata entity. Once the customized metadata **216** is provided by the customizer, it will be used to customize the application **208** of the mobile computing device **206**. When the application **208** is updated or a new software package is installed on mobile computing device **206**, the customizations are installed and applied automatically without user intervention.

FIG. **3** illustrates a metadata structure and metadata customization in accordance with embodiments of the invention. The metadata structure is illustrated by a portion of a metadata structure tree **250**. It will be appreciated that the portion of tree **250** shown in FIG. **3** is illustratively but a very small portion of a much larger tree that defines customized metadata **216** for system **200**. Portions of the metadata structure tree define metadata entities, such as metadata entity **252**, which correspond to entities **220** in data storage system **202**.

The portion of metadata structure tree **250** shown in FIG. **3** illustrates that the metadata includes a Form section (user interface content) which itself includes a Customer_Maintenance_Screen. The Customer_Maintenance_Screen includes fields (data content) which have a plurality of Tab controls. Tab control **1** has a Field **1** associated with it. Field **1** has a plurality of properties, including the field name, the background color for the field, whether the field is enabled or disabled, the length of the field, and the data type for the field (which in this case is Max Value). Of course, the field can have a plurality of additional properties as well.

In order to customize a metadata structure **250**, the customizer **242** inputs the customization specification through customization tool **240**. Customization of the metadata **216** can be achieved through direct input of the setting, or an addition of a node. For example, the background color for the field having a name "foo" is yellow in metadata structure **250**. Assume that a customizer wishes to change the background color to blue. In that case, the customizer makes the change by directly inputting the color change to blue through the graphical user interface provided by the customization tool **240**.

Alternatively, customization of metadata **216** can be achieved by using deltas. A delta represents a change in the metadata structure **250** from its original form. A customization can contain any number, *n*, of deltas, each delta representing a specific change relative to a known instance of a base structure. Further, the delta need not simply represent a change to an existing node, but can represent the addition of a new node in the metadata structure **250**.

For example, in order to make the change described above with respect to the field named "foo", the customizer will make a single customization containing a single delta. The customization is relative to the field "foo" under Tab **1** of the Customer_Maintenance_Screen. The customization can be stored in a separate part of the metadata store (database or data store **218**) or in a metadata customization entity **252** which is mapped to the relational database **218**. A metadata customization table **254** in relational database **218** contains a metadata ID identifying the background color property of field **1** under tab **1** of the fields in the Customer_Maintenance_Screen portion of the Forms. Table **254** also includes

delta information which identifies the delta, that being that the background color of the field is changed to blue. Thus, the delta is not a copy of the source that has been modified. Instead, it is only a specification of which value in structure **250** should be modified. By only tracking deltas, it is possible for many modifications to be dynamically applied to a target entity.

FIGS. **4-6** illustrate an example of a customization of application **208** through metadata customization. In the example illustrated in FIGS. **4-6** assume that a car dealership Mortens Autos purchases a financial software package. After installation and running of the application package, Mortens Autos customizes the product to add fields (data content) to track each customer car preferences (such as color, engine, make/model, etc.). Assume that Mortens Autos also adds new fields to a customer screen for the customer car preferences, and removes a number of unused fields.

FIG. **4** illustrates a screen shot **260** of a default customer screen displayed by the financial package purchased by Mortens Autos that has been generated in accordance with a default or base metadata entity. It can be seen that screen **260** includes order summary fields which are not generally used in the car dealer industry. FIG. **4** also shows the same customer screen **262** after customizations to the metadata entity have been implemented. The original order summary fields have been replaced with fields indicating the customer's last purchase and last purchase date. In addition, a car preferences tab has been added to display the customer's car preferences. This is all accomplished simply by customizing the associated metadata **216** using the customization tool **240** of system **200**, as discussed above.

Next, assume that another business solutions provider, Consoto, introduces electronic mail notifications for service reminders. Assume further that the customer entity provided by Consoto also adds a string to the customer entity for the name of the customer's favorite technician and a text box for a new field to the customer screen. An example of Consoto's customer screen is illustrated in FIG. **5**. Assume that Mortens Autos buys, from Consoto, a software package to run the service department.

After the installation, all previous customizations still work without manual intervention or rework. This is shown in FIG. **6**. For instance, the customer's car preferences field is shown on the screen and the original Order fields are removed from the screen. Similarly, Consoto's changes to the customer screen are also provided. Specifically, the new fields on the customer entity and text boxes on the customer screen are included. As is described above, when the new software package is installed, the customizations take effect without automatically, without user intervention.

Another aspect of the present invention allows for users of the business application **208** on remote or mobile computing devices **206** to control which customized metadata entities will be rendered thereon. This allows the user to avoid loading large amounts of unnecessary data to the mobile computing device **206**, which generally has a limited data storage capacity as compared to non-mobile computing devices, such as desktop computers. Additionally, this aspect of the present invention allows the user to select only those entities that are relevant to his or her business practice. Such filtering of the customized metadata allows the user to operate the application more efficiently by avoiding having to sort through a large number of entities, which the user is not associated with.

A method of customizing a software implemented business process or application in accordance with the above-described aspects of the present invention will be discussed

with reference to the flowchart of FIG. **7**. At step **270** of the method, customized metadata **216** defining entities **220** (FIG. **2**) is provided. This step is preferably performed as described above using customization tool **240**. The customized metadata **216** and data **224** corresponding to the entities **220** are then stored in a first data store **218** of system **202**, at step **272**.

Next, at step **274**, a subscription list of the customized metadata entities **216** is provided on the mobile computing device **206**. The subscription list is defined by subscription metadata **276** stored in a subscription data store of mobile computing device **206**, as shown in FIG. **2**. The subscription list or metadata **276** identifies a subset of the customized metadata entities **216** contained in data store **218** of data storage system **202**.

The subscription metadata **276** is preferably generated by the user through a subscription interface **278** shown in FIG. **2**. Subscription interface **278** preferably includes a graphical user interface. In accordance with one embodiment of the invention, the graphical user interface provides a list of the customized entities **216** by name that can be selected by the user for inclusion in the subscription list **276**. The graphical user interface preferably organizes the customized metadata entities **216** for presentation to the user or provides options to the user as to how the subscriptions to the customized metadata entities are to be presented. An exemplary graphical user interface **280** is shown in FIG. **8A**, which provides the user options of displaying all of the subscriptions or accounts by selecting check box **281**, only the active accounts by selecting check box **282**, accounts by Postal/ZIP code by selecting check box **283**, or the accounts organized by state by selecting check box **284**, for example. The user can also designate the particular accounts that will comprise the main list of customized metadata entities **216** or accounts from which the subscriptions are made, and the particular states or Postal/ZIP codes that are to be used to organize the main list of accounts by selecting, for example, the corresponding arrow icon **285**.

Once a selection of the desired list of customized metadata entities **216** is made by the user of mobile computing device **206**, the customized metadata entities **216** or accounts are presented accordingly. FIG. **8B** is an example of a graphical user interface **286** presenting a list **287** of customized metadata entities **216** or accounts in accordance with the user's selection from the options presented in the graphical user interface **280** shown in FIG. **8A**. The user can select individual customized metadata entities **288** or accounts from the presented list **287** in accordance with conventional methods. In the present example, the user selects individual customized metadata entities **288** or accounts for subscription by highlighting an individual entity **288** and selecting arrow **289** to add the entity **288** to a subscription list **290**. Individual entities **288** can be deselected from the subscription list **290** in a similar manner by highlighting the particular entity **288** and selecting arrow **291** to remove it from the list **290**.

The graphical user interface **280** can also provide the user with information as to an estimated amount of memory storage that remains available to the mobile computing device **206** after a synch is performed to load the entities **216** of the subscription list **290** into the device **206**.

It should be understood that many other types of graphical user interfaces can be generated by subscription interface **278** to provide the user with a means for selecting the desired customized metadata entities **216**, such as drop-down menus and other suitable interfaces. Once the user makes the selection of the customized entities to be included

11

in the subscription list 290, the subscription metadata 276 that defines the subscription list 290 is generated and stored in a subscription data store.

At step 292 of the method of FIG. 7, the customized metadata or entities 216 corresponding to the entities 282 identified in the subscription list 276 are sent to the mobile computing device 206. In accordance with one embodiment of the invention, this data transmission is performed using synchronizer 294, shown in FIG. 2. Synchronizer 294 includes sync engines 296 and 298, which are configured to form a communication link between central and mobile data storage systems 202 and 210 and allow system 200 perform a sync operation between central and mobile databases 218 and 214 in accordance with known methods. Such sync operations are preferably substantially performed in the background to allow the user of the mobile computing device 206 to access and operate the application 208 without interruption.

During a sync operation between the central and mobile data storage systems 202 and 210, the subscription metadata 276 is read to determine which customized metadata entities 216 are to be sent to the mobile computing device 206. Next, only the customized metadata entities 282 identified in the subscription list 276 are sent to mobile computing device 206, which are then stored in data store 214, as indicated at step 300 of the method. Alternatively, when mobile computing device 206 already includes customized metadata 212 in data store 214, the synch operation between the central and mobile databases 218 and 214 can simply involve replacing the existing or old customized metadata with the new customized metadata. Preferably, only the customized metadata 216 contained in central data store that has been updated since the last synching operation is sent to the mobile computing device 206 to either replace the corresponding old customized metadata 212 or be added to the metadata 212.

Preferably, the data 224 that corresponds to the customized metadata entities 282 identified in the subscription metadata 276 are also transmitted to mobile computing device 206 and stored in data store 214 by data accessing system 230. The application 208 then renders or populates the entities defined by the customized metadata entities 212 using the corresponding sent data 226 contained in data store 214. The populated or rendered entities 222 can then be displayed for the user on the mobile computing device 206 in accordance with the form or view defined by the corresponding sent customized metadata 212.

One alternative to transmitting the customized metadata 216 and the corresponding data 224 separately to mobile computing device 206 is to transmit rendered or populated entities 220 that correspond to the customized entities 282 identified in the subscription list 276. This embodiment of the method of the present invention is illustrated in the flowchart of FIG. 9. The method initially begins in accordance with steps 270, 272, and 274 of the method discussed above. Accordingly, customized metadata 216 is provided at step 302, the customized metadata and corresponding data are stored at step 304, and a subscription list of the entities defined by subscription metadata is provided at step 306. However, rather than sending the customized metadata 216 and the corresponding data 224 separately to database 214 of mobile computing device 206, the entities 282 identified in the subscription list 276 are rendered or populated, at step 308, with the corresponding data 224 in accordance with the customized metadata 216 to form populated entities or objects. Next, at step 310, the populated entities are sent to the mobile computing device 312 (FIG. 2). Finally, at step

12

314, the populated entities are stored in an object data store 316 of the mobile computing device 312, as illustrated in FIG. 2. Preferably, only the populated entities that have changed since the last synching operation are sent to mobile computing device 312 to replace old populated entities contained in the object data store 316 or to be added thereto. As a result, there is no need to render the entities defined by the customized metadata 216 in the mobile computing device 312. Instead, application 208 of mobile computing device 312 can directly access the populated entities and display them to the user.

Although the present invention has been described with reference to particular embodiments, workers skilled in the art will recognize that changes may be made in form and detail without departing from the spirit and scope of the invention.

What is claimed is:

1. A computer-implemented method performed by a client computing device, the method comprising:
 - receiving an indication of a data object selection input associated with a client application;
 - based on the indication of the data object selection input, selecting a subset of data objects, the subset comprising some, but not all, of a set of data objects associated with a remote server computing system that is remote from the client computing device;
 - generating a subscription list that identifies the selected subset;
 - transmitting an indication of the subscription list to the remote server computing system;
 - receiving, from the remote server computing system, generated customized metadata that:
 - is based on the subscription list, and
 - represents a change in a metadata structure that defines a customization to the subset of data objects;
 - generating a user interface display that is associated with the client application and utilizes a customized layout, defined by the received customized metadata, to replace a first layout associated with the user interface display; and
 - generating a rendering instruction to render the user interface display on the client computing device.
2. The computer-implemented method of claim 1, wherein the customized metadata includes a metadata delta that represents a change in a metadata structure that defines the user interface display.
3. The computer-implemented method of claim 2, wherein the metadata structure defines user interface content.
4. The computer-implemented method of claim 3, wherein the metadata delta identifies a change in a metadata value from a default value.
5. The computer-implemented method of claim 3, wherein the customized metadata includes a plurality of metadata deltas, each metadata delta representing a specific change to a portion of the user interface content.
6. The computer-implemented method of claim 3, wherein the metadata delta represents an addition of a new node in the metadata structure.
7. The computer-implemented method of claim 3, wherein the metadata structure and the changed metadata structure are stored separately in a metadata store associated with the client computing device.
8. The computer-implemented method of claim 1, the method comprising:

13

generating a representation of a subscription user interface that includes a data object selection user input mechanism;

receiving the indication of the data object selection input through the data object selection user input mechanism;

storing the subscription list within a data store of the client computing device; and

utilizing the customized layout to replace a default layout.

9. The computer-implemented method of claim 8, wherein the customized metadata corresponds to the data objects identified in the subscription list, and identifies at least one of:

a field that is removed from the user interface display; and
a field that is added to the user interface display.

10. The computer-implemented method of claim 1, wherein the subscription list is transmitted from the client computing device and the customized metadata is received as a response to said transmission of the subscription list.

11. The computer-implemented method of claim 1, wherein the subscription list is transmitted over a network, from the client computing device to a synchronizer.

12. The computer-implemented method of claim 11, wherein the customized metadata is received, over the network, by the client computing device from the synchronizer.

13. The computer-implemented method of claim 1, wherein the customized metadata includes metadata corresponding to orders.

14. The computer-implemented method of claim 1, wherein the application is associated with an enterprise resource management application.

15. A client computing device comprising:
a communication interface configured to communicate with a remote server computing system, that is remote from the client computing device, over a communication network;

one or more processors; and

memory storing instructions which, when executed by the one or more processors, configure the client computing device to:

receive an indication of a data object selection input associated with a client application;

based on the indication of the data object selection input, select a subset of data objects, the subset comprising some, but not all, of a set of data objects associated with a remote server computing system that is remote from the client computing device;

generate a subscription list that identifies the selected subset;

transmit, by the client computing device to the remote server computing system over the communication network, an indication of the subscription list;

14

receive, by the client computing device from the remote server computing system, generated customized metadata that:

is based on the subscription list, and

defines a customization to the subset of data objects; generate, by the client computing system, a user interface that is associated with the client application and utilizes a customized layout, defined by the received customized metadata, to replace a first layout associated with the user interface; and

generate a rendering instruction to render the user interface.

16. The client computing device of claim 15, wherein the customized metadata includes a metadata delta that represents a change in a metadata structure that defines the user interface.

17. The client computing device of claim 16, wherein the metadata structure defines user interface content and the metadata delta identifies a change in a metadata value from a default value.

18. The client computing device of claim 15, wherein the instructions configure the client computing device to:

transmit the subscription list over a network to a synchronizer; and

receive the customized metadata over the network from the synchronizer.

19. A computer-implemented method performed by a computing system comprising:

receiving a subscription list from a client computing device that is remote from the computing system over a communication network, the subscription list identifying a subset of data objects, the subset comprising some, but not all, of a set of data objects that are defined by a metadata structure stored in association with the computing system;

generating customized metadata that:

corresponds to the subset of data objects in the subscription list, and

represents a change to the metadata structure that defines a customization to the subset of data objects; and

transmitting, to the client computing device, the generated customized metadata that represents a change, to a user interface display associated with a client application on the client computing device, that replaces a first layout associated with the user interface display with a customized layout.

20. The computer-implemented method of claim 19, wherein the generated customized metadata comprising a first metadata delta that identifies a change in a metadata value from a default value and a second metadata delta that identifies an addition of a new node in the metadata structure.
