METHOD FOR PRODUCING OPTOELECTRONIC DEVICES COMPRISING LIGHT-EMITTING DIODES

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is the national phase of International Application No. PCT/FR2014/052472, titled, filed on Sep. 30, 2014, which claims the priority benefit of French Application No. 13/59413, filed on Sep. 30, 2013, which applications are hereby incorporated by reference to the maximum extent allowable by law.

BACKGROUND

The present invention generally relates to methods of manufacturing optoelectronic devices based on semiconductor materials. The present invention more specifically relates to methods of manufacturing optoelectronic devices comprising light-emitting diodes formed by three-dimensional elements, particularly semiconductor microwires or nanowires.

DISCUSSION OF THE RELATED ART

The term "optoelectronic devices with light-emitting diodes" designates devices capable of converting an electric signal into an electromagnetic radiation, and particularly devices dedicated to emitting an electromagnetic radiation, particularly light. Examples of three-dimensional elements capable of forming light-emitting diodes are microwires or nanowires comprising a semiconductor material based on a compound mainly comprising at least one group-III element and one group-V element (for example, gallium nitride GaN), called III-V compound hereafter, or mainly comprising at least one group-II element and one group-VI element (for example, zinc oxide ZnO), called II-VI compound hereafter.

The three-dimensional elements, particularly semiconductor microwires or nanowires, are generally formed on a substrate which is then sawn to delimit individual optoelectronic devices. Each optoelectronic device is then arranged in a package, particularly to protect the three-dimensional elements. The package may be attached to a support, for example, a printed circuit.

A disadvantage of such an optoelectronic device manufacturing method is that the steps of protecting the three-dimensional semiconductor elements have to be performed separately for each optoelectronic device. Further, the bulk of the package may be significant as compared with the active area of the optoelectronic device comprising the light-emitting diodes.

SUMMARY

Thus, an object of an embodiment is to at least partly overcome the disadvantages of previously-described optoelectronic devices comprising light-emitting diodes, particularly with microwires or nanowires.

Another object of an embodiment is to suppress the individual protection packages of optoelectronic devices comprising light-emitting diodes.

Another object of an embodiment is for optoelectronic devices comprising light-emitting diodes made of semiconductor material to be capable of being manufactured at an industrial scale and at a low cost.

Thus, an embodiment provides a method of manufacturing optoelectronic devices comprising the successive steps of:

(a) providing a substrate comprising a first surface;

(b) forming, on the first surface, assemblies of light-emitting diodes comprising, conical or tapered wire-shaped semiconductor elements;

(c) forming, for each assembly of light-emitting diodes, an electrode layer covering each light-emitting diode of said assembly and a conductive layer covering the electrode layer around the light-emitting diodes of said assembly;

(d) covering the entire first surface of a layer encapsulating the light-emitting diodes;

(e) decreasing the substrate thickness, the substrate comprising, after step (e), a second surface opposite to the first surface;

(f) forming a conductive element insulated from the substrate and crossing the substrate from the second surface all the way to at least the first surface, the conductive element being in contact with the conductive layer;

(g) forming, on the second surface, at least one first conductive pad in contact with the substrate; and

(h) cutting the obtained structure to separate each assembly of light-emitting diodes.

According to an embodiment, the method comprises, at step (f), forming, on the second surface, at least one second conductive pad in contact with the conductive element.

According to an embodiment, the method comprises forming at least one additional conductive element, insulated from the substrate and crossing the substrate from the second surface all the way to at least the first surface, and in contact with the base of at least one of the light-emitting diodes.

According to an embodiment, the forming of the conductive element successively comprises, after step (e), etching an opening in the substrate from the second surface, forming an insulating layer at least on the lateral walls of the opening, and forming a conductive layer covering the insulating layer, or filling the opening with a conductive material.

According to an embodiment, the forming of the conductive element comprises, before step (b), etching an opening in the substrate from the first surface across a portion of the substrate thickness, the opening being opened on the second surface after the substrate thinning step.

According to an embodiment, the electrode layer and the conductive layer are further formed in the opening.

According to an embodiment, the method comprises, before step (b), forming an insulating portion at least on the lateral walls of the opening and filling the opening with a conductive material.

According to an embodiment, at step (e), the substrate is totally removed.

According to an embodiment, the method further comprises, for each assembly of light-emitting diodes, depositing at least one conductive layer in contact with the bases of the diodes of said assembly.

According to an embodiment, the method comprises, before step (e), a step of attaching a support to the layer encapsulating the light-emitting diodes.

According to an embodiment, the layer encapsulating the light-emitting diodes comprises phosphors between the light-emitting diodes.

According to an embodiment, the method comprises a step of forming a layer of phosphors covering the layer encapsulating the light-emitting diodes or covering the support.

According to an embodiment, the method comprises a step of forming a layer, between the layer encapsulating the light-emitting diodes and the phosphor layer, capable of transmitting the light rays emitted by the light-emitting diodes and of reflecting the light rays emitted by the phosphors.

According to an embodiment, the method comprises a step of forming reflectors around the light-emitting diodes between the substrate and the layer encapsulating the light-emitting diodes and having a height greater by 50% than the height of the light-emitting diodes.

BRIEF DESCRIPTION OF THE DRAWINGS

The foregoing and other features and advantages will be discussed in detail in the following non-limiting description of specific embodiments in connection with the accompanying drawings, among which:

FIG. **1** is a partial simplified top view of an example of a semiconductor substrate wafer having a plurality of optoelectronic devices comprising microwires or nanowires formed thereon;

FIGS. **2**A to **2**F are partial simplified cross-section views of structures obtained at successive steps of an embodiment of a method of manufacturing optoelectronic devices comprising microwires or nanowires;

FIGS. **3**A and **3**B are partial simplified cross-section views of structures obtained at successive steps of another embodiment of a method of manufacturing optoelectronic devices comprising microwires or nanowires;

FIGS. **4** and **5** are partial simplified cross-section views of structures obtained by other embodiments of methods of manufacturing optoelectronic devices comprising microwires or nanowires;

FIGS. **6**A to **6**C are partial simplified cross-section views of structures obtained at successive steps of another embodiment of a method of manufacturing optoelectronic devices comprising microwires or nanowires;

FIGS. **7**A and **7**B are partial simplified cross-section views of structures obtained at successive steps of another embodiment of a method of manufacturing optoelectronic devices comprising microwires or nanowires;

FIGS. **8** to **10** are partial simplified cross-section views of structures obtained by other embodiments of methods of manufacturing optoelectronic devices comprising microwires or nanowires;

FIGS. **11**A to **11**D are partial simplified cross-section views of structures obtained at successive steps of another embodiment of a method of manufacturing optoelectronic devices comprising microwires or nanowires;

FIGS. **12**A to **12**E are partial simplified cross-section views of structures obtained at successive steps of another embodiment of a method of manufacturing optoelectronic devices comprising microwires or nanowires;

FIG. **13** is a partial simplified cross-section view of an embodiment of an optoelectronic device comprising microwires or nanowires formed on a substrate wafer before sawing of the substrate;

FIG. **14** is a partial simplified top view of the optoelectronic device of FIG. **13**; and

FIGS. **15** to **27** are partial simplified cross-section views of embodiments of optoelectronic devices comprising microwires or nanowires.\

DETAILED DESCRIPTION

For clarity, the same elements have been designated with the same reference numerals in the various drawings and, further, as usual in the representation of electronic circuits, the various drawings are not to scale. Further, only those elements which are useful to the understanding of the present description have been shown and will be described. In particular, the optoelectronic device control means described hereafter are within the abilities of those skilled in the art and are not described.

In the following description, unless otherwise indicated, the terms "substantially", "approximately", and "in the order of" mean "to within 10%". Further, "compound mainly formed of a material" or "compound based on a material" means that a compound comprises a proportion greater than or equal to 95% of said material, this proportion being preferentially greater than 99%.

The present description relates to optoelectronic devices comprising three-dimensional elements, for example, microwires, nanowires, conical elements, or tapered elements. In the following description, embodiments are described for optoelectronic devices comprising microwires or nanowires. However, these embodiments may be implemented for three-dimensional elements other than microwires or nanowires, for example, pyramid-shaped three-dimensional elements.

The term "microwire" or "nanowire" designates a three-dimensional structure having an elongated shape along a preferential direction, having at least two dimensions, called minor dimensions, in the range from 5 nm to 2.5 μm, preferably from 50 nm to 2.5 μm, the third dimension, called major dimension, being at least equal to 1 time, preferably at least 5 times, and more preferably still at least 10 times, the largest of the minor dimensions. In certain embodiments, the minor dimensions may be smaller than or equal to approximately 1 μm, preferably in the range from 100 nm to 1 μm, more preferably from 100 nm to 300 nm. In certain embodiments, the height of each microwire or nanowire may be greater than or equal to 500 nm, preferably in the range from 1 μm to 50 μm.

In the following description, the term "wire" is used to mean "microwire or nanowire". Preferably, the average line of the wire which runs through the centers of gravity of the cross-sections, in planes perpendicular to the preferential direction of the wire, is substantially rectilinear and is called "axis" of the wire hereafter.

FIG. **1** is a partial simplified top view of a wafer **10** of a semiconductor substrate having wires formed thereon. As an example, it is a single-crystal silicon wafer having an initial thickness in the range from 500 μm to 1,500 μm, for example, approximately 725 μm, and having a diameter in the range from 100 mm to 300 mm, for example, approximately 200 mm. Advantageously, it is a silicon wafer currently used in methods of circuit manufacturing in microelectronics, particularly based on metal-oxide field-effect transistors or MOS transistors. As a variation, any other single-crystal semiconductor compatible with microelectronics manufacturing methods such as germanium may be used. Preferably, the semiconductor substrate is doped to decrease the electric resistivity of the substrate to an accept-

able level for the series resistance of the light-emitting diode and to a resistivity close to that of metals, preferably smaller than a few mohm·cm.

A plurality of optoelectronic devices **14** comprising light-emitting diodes are simultaneously formed on wafer **10**. Dotted lines **12** show an example of separation limits between optoelectronic devices **14**. The number of light-emitting diodes may be different according to optoelectronic devices **14**. Optoelectronic devices **14** may take up portions of wafer **10** having different surface areas. Optoelectronic devices **14** are separated by steps of sawing wafer **10** along sawing paths shown by lines **12**.

According to an embodiment, the method of manufacturing optoelectronic devices **14** comprising light-emitting diodes formed of three-dimensional elements, particularly semiconductor wires, comprises the steps of:

forming the light-emitting diodes of the optoelectronic devices on a first surface of wafer **10**;

protecting the assembly of light-emitting diodes with an encapsulation layer;

forming contact pads for the biasing of the light-emitting diodes for each optoelectronic device on the side opposite to the encapsulation layer; and

sawing wafer **10** to separate the optoelectronic devices.

The encapsulation layer protects the light-emitting diodes during the contact pad forming steps and is kept after the optoelectronic devices have been separated. The encapsulation layer keeps on protecting the light-emitting diodes after the substrate has been sawn. It is then not necessary to provide, for each optoelectronic device, a protection package for the light-emitting diodes, attached to the device after the optoelectronic devices have been separated. The bulk of the optoelectronic device may be decreased.

Further, the step of protecting the light-emitting diodes of optoelectronic devices **14** is carried out by encapsulation of the wires in an encapsulation layer which is deposited all over wafer **10** before the step of sawing wafer **10**. This step is thus carried out only once, for the all the optoelectronic devices **14** formed on wafer **10**. The manufacturing cost of each optoelectronic device is thus decreased.

Thus, the encapsulation is entirely performed at the wafer scale after the microwire or nanowire manufacturing steps. Such a collective encapsulation at the wafer scale enables to decrease the number of steps dedicated to the encapsulation, and thus the encapsulation cost. Further, the surface area of the final encapsulated optoelectronic component is almost identical to that of the active area of the chip taking part in the light emission, which enables to decrease the dimensions of the optoelectronic component.

FIGS. **2**A to **2**F are partial simplified cross-section views of obtained structures corresponding to an optoelectronic device at successive steps of an embodiment of a method of manufacturing optoelectronic devices formed with wires such as previously described and capable of emitting an electromagnetic radiation. FIGS. **2**A to **2**F correspond to one of the optoelectronic devices formed on substrate **10**.

FIG. **2**A shows a structure comprising, from bottom to top in FIG. **2**A:

- semiconductor substrate **10** comprising an upper surface **22**;
- seed pads **24** promoting the growth of wires and arranged on surface **22**;
- wires **26** (two wires being shown) of height H**1**, each wire **26** being in contact with one of seed pads **24**, each wire **26** comprising a lower portion **28**, of height H**2**, in contact with seed pad **24** and an upper portion **30**, of height H**3**, continuing lower portion **28**;
- an insulating layer **32** extending on surface **22** of substrate **10** and on the lateral sides of lower portion **28** of each wire **26**;
- a shell **34** comprising a stack of semiconductor layers covering each upper portion **30**;
- a layer **36** forming a first electrode covering each shell **30** and further extending on insulating layer **32**; and
- a conductive layer **38** covering electrode layer **36** between wires **26** without extending on wires **26**.

The assembly formed by each wire **26**, the associated seed pad **24**, and shell **34** forms a light-emitting diode DEL. The base of diode DEL corresponds to seed pad **24**. Shell **34** particularly comprises an active layer which is the layer from which most of the electromagnetic radiation delivered by light-emitting diode DEL is emitted.

Substrate **10** may correspond to a one-piece structure or correspond to a layer covering a support made of another material. Substrate **10** for example is a semiconductor substrate, preferably a semiconductor substrate compatible with manufacturing methods implemented in microelectronics, for example, a substrate made of silicon, germanium, or an alloy of these compounds. The substrate is doped so that the substrate resistivity is lower than a few mohm·cm.

Preferably, substrate **10** is a semiconductor substrate, such as a silicon substrate. Substrate **10** may be doped with a first conductivity type, for example, N-type doped. Surface **22** of substrate **20** may be a<100> surface.

Seed pads **24**, also called seed islands, are made of a material promoting the growth of wires **26**. As a variation, seed pads **24** may be replaced with a seed layer covering surface **22** of substrate **10**. In the case of seed pads, a treatment may further be provided to protect the lateral edges of the seed pads and the surface of the substrate portions which are not covered with the seed pads to prevent wires from growing on the lateral sides of the seed pads and on the surface of the substrate portions which are not covered with the seed pads. The treatment may comprise forming a dielectric region on the lateral sides of the seed pads and extending on top of and/or inside of the substrate and connecting, for each pair of pads, one of the pads of the pair to the other pad in the pair, with no wire growth on the dielectric region.

As an example, the material forming seed pads **24** may be a nitride, a carbide, or a boride of a transition metal from column IV, V, or VI of the periodic table of elements or a combination of these compounds. As an example, seed pads **24** may be made of aluminum nitride (AlN), boron (B), boron nitride (BN), titanium (Ti), titanium nitride (TiN), tantalum (Ta), tantalum nitride (TaN), hafnium (Hf), hafnium nitride (HfN), niobium (Nb), niobium nitride (NbN), zirconium (Zr), zirconium borate (ZrB2), zirconium nitride (ZrN), silicon carbide (SiC), tantalum carbo-nitride (TaCN), magnesium nitride in MgxNy form, where x is approximately equal to 3 and y is approximately equal to 2, for example, magnesium nitride in Mg3N2 form or magnesium gallium nitride (MgGaN), tungsten (W), tungsten nitride (WN), or a combination thereof.

Seed pads **24** may be doped with the same conductivity type as substrate **10** or with the opposite conductivity type.

Insulating layer **32** may be made of a dielectric material, for example, silicon oxide (SiO2), silicon nitride (SixNy, where x is approximately equal to 3 and y is approximately equal to 4, for example, Si3N4), aluminum oxide (Al2O3), hafnium oxide (HfO2), or diamond. As an example, the thickness of insulating layer **32** is in the range from 5 nm to 800 nm, for example, equal to approximately 30 nm.

Wires **26** may be at least partly formed based on at least one semiconductor material. The semiconductor material may be silicon, germanium, silicon carbide, a III-V compound, a II-VI compound, or a combination of these compounds.

Wires **26** may be at least partly formed of semiconductor materials mainly comprising a III-V compound, for example, III-N compounds. Examples of group-III elements comprise gallium (Ga), indium (In), or aluminum (Al). Examples of III-N compounds are GaN, AN, InN, InGaN, AlGaN, or AlInGaN. Other group-V elements may also be used, for example, phosphorus or arsenic. Generally, the elements in the III-V compound may be combined with different molar fractions.

Wires **26** may be at least partly formed based on semiconductor materials mainly comprising a II-VI compound. Examples of group-II elements comprise group-IIA elements, particularly beryllium (Be) and magnesium (Mg), and group-IIB elements, particularly zinc (Zn) and cadmium (Cd). Examples of group—VI elements comprise group-VIA elements, particularly oxygen (O) and tellurium (Te). Examples of II-VI compounds are ZnO, ZnMgO, CdZnO, or CdZnMgO. Generally, the elements in the II-VI compound may be combined with different molar fractions.

Wires **26** may comprise a dopant. As an example, for III-V compounds, the dopant may be selected from the group comprising a group-II P-type dopant, for example, magnesium (Mg), zinc (Zn), cadmium (Cd), or mercury (Hg), a group-IV P-type dopant, for example, carbon (C), or a group-IV N-type dopant, for example, silicon (Si), germanium (Ge), selenium (Se), sulfur (S), terbium (Tb), or tin (Sn).

The cross-section of wires **26** may have different shapes, such as, for example, oval, circular, or polygonal, particularly triangular, rectangular, square, or hexagonal. It should thus be understood that the term "diameter" mentioned in relation with a cross-section of a wire or of a layer deposited on this wire designates a quantity associated with the surface area of the targeted structure in this cross-section, corresponding, for example, to the diameter of the disk having the same surface area as the wire cross-section. The average diameter of each wire **26** may be in the range from 50 nm to 2.5 μm. Height H**1** of each wire **26** may be in the range from 250 nm to 50 μm.

Each wire **26** may have an elongated semiconductor structure along an axis D substantially perpendicular to surface **22**. Each wire **26** may have a general cylindrical shape.

The axes of two wires **26** may be distant by from 0.5 μm to 10 μm, and preferably from 1.5 μm to 4 μm. As an example, wires **26** may be regularly distributed. As an example, wires **26** may be distributed in a hexagonal network.

As an example, lower portion **28** of each wire **26** is mainly formed of the III-N compound, for example, gallium nitride, having a doping of the first conductivity type, for example, silicon. Lower portion **28** extends up to a height H**2** which may be in the range from 100 nm to 25 μm.

As an example, upper portion **30** of each wire **26** is at least partially made of a III-N compound, for example, GaN. Upper portion **30** may be doped with the first conductivity type, or may not be intentionally doped. Upper portion **30** extends up to a height H**3** which may be in the range from 100 nm to 25 μm.

In the case of a wire **26** mainly made of GaN, the crystal structure of wire **26** may be of wurtzite type, the wire extending along axis C. The crystal structure of wire **26** may also be of cubic type.

Shell **34** may comprise a stack of an active layer covering upper portion **30** of the associated wire **26** and of a bonding layer between the active layer and electrode **36**.

The active layer is the layer from which most of the radiation delivered by light-emitting diode DEL is emitted. According to an example, the active layer may comprise confinement means, such as multiple quantum wells. It is for example formed of an alternation of GaN and of InGaN layers having respective thicknesses from 5 to 20 nm (for example, 8 nm) and from 1 to 10 nm (for example, 2.5 nm). The GaN layers may be doped, for example of type N or P. According to another example, the active layer may comprise a single InGaN layer, for example, having a thickness greater than 10 nm.

The bonding layer may correspond to a semiconductor layer or to the stack of semiconductor layers and enables to form a P-N or P-I-N junction with the active layer andor upper portion **30**. It enables to inject holes into the active layer via electrode **36**. The stack of semiconductor layers may comprise an electron barrier layer made of a ternary alloy, for example, aluminum gallium nitride (AlGaN) or aluminum indium nitride (AlInN) in contact with the active layer and an additional layer, to provide a good electric contact between electrode **36** and the active layer, for example, made of gallium nitride (GaN) in contact with the electron barrier layer and with electrode **36**. The bonding layer may be doped with the conductivity type opposite to that of portion **30**, for example, P-type doped.

Electrode **36** is capable of biasing the active layer of each wire **26** and of letting through the electromagnetic radiation emitted by light-emitting diodes DEL. The material forming electrode **36** may be a transparent and conductive material such as indium tin oxide (ITO), aluminum zinc oxide, or graphene. As an example, electrode **36** has a thickness in the range from 10 nm to 150 nm according to the desired emission wavelength.

Conductive layer **38** may be a single layer or correspond to a stack of two layers or of more than two layers. Conductive layer **38** may further be capable of at least partly reflecting the radiation emitted by light-emitting diodes DEL. As an example, conductive layer **38** corresponds to a metal monolayer. According to another example, conductive layer **38** corresponds to a stack of layers for example comprising a metal layer covered with a dielectric layer or with a plurality of dielectric layers. The metal layer of conductive layer **38** may be formed on a bonding layer, for example, made of titanium. As an example, the material forming the metal layer of conductive layer **38** (monolayer or multilayer) may be aluminum, an alloy based on aluminum, particularly AlSiz, AlxCuy (for example, with x equal to 1 and y equal to 0.8%), silver, gold, nickel, chromium, rhodium, ruthenium, palladium, or an alloy of two of these compounds or of more than two of these compounds. As an example, conductive layer **38** (monolayer or multilayer) has a thickness in the range from 100 nm to 2,000 nm.

An embodiment of a manufacturing method providing the structure shown in FIG. **2**A comprises the steps of:

(1) Forming, on surface **22** of substrate **10**, seed pads **24**.

Seed pads **24** may be obtained by a method such as chemical vapor deposition (CVD) or metal-organic chemical vapor deposition (MOCVD), also known as metal-organic vapor phase epitaxy (MOVPE). However, methods such as molecular-beam epitaxy (MBE), gas-source MBE

(GSMBE), metal-organic MBE (MOMBE), plasma-assisted MBE (PAMBE), atomic layer epitaxy (ALE), hydride vapor phase epitaxy (HVPE) may be used, as well as an atomic layer deposition (ALD). Further, methods such as evaporation or reactive cathode sputtering may be used.

When seed pads **24** are made of aluminum nitride, they may be substantially textured and have a preferred polarity. The texturing of pads **24** may be obtained by an additional treatment carried out after the deposition of seed pads **24**. It for example is an anneal under an ammonia flow (NH3).

(2) Protecting the portions of surface **22** of substrate **10** which are not covered with seed pads **24** to avoid the subsequent growth of wires on these portions. This may be obtained by a nitriding step which causes the forming, at the surface of substrate **10**, between seed pads **24**, of silicon nitride regions (for example, Si3N4).

(3) Growing lower portion **28** of each wire **26** up to height H**2**. Each wire **26** grows from the top of the underlying seed pad **24**.

Wires **26** may be grown by a process of CVD, MOCVD, MBE, GSMBE, PAMBE, ALE, HVPE type. Further, electrochemical processes may be used, for example, chemical bath deposition (CBD), hydrothermal processes, liquid aerosol pyrolysis, or electro-deposition.

As an example, the wire growth method may comprise injecting into a reactor a precursor of a group-III element and a precursor of a group-V element. Examples of precursors of group-III elements are trimethylgallium (TMGa), triethylgallium (TEGa), trimethylindium (TMIn), or trimethylaluminum (TMAl). Examples of precursors of group-V elements are ammonia (NH3), tertiarybutylphosphine (TBP), arsine (AsH3), or unsymmetrical dimethylhydrazine (UDMH).

According to an embodiment of the invention, in a first phase of growth of the wires of the III-V compound, a precursor of an additional element is added in excess, in addition to the precursors of the III-V compound. The additional element may be silicon (Si). An example of a precursor of silicon is silane (SiH4).

As an example, in the case where upper portion **28** is made of heavily-doped N-type GaN, a MOCVD-type method may be implemented by injection, into a showerhead-type MOCVD reactor, of a gallium precursor gas, for example, trimethylgallium (TMGa) and a nitrogen precursor gas, for example, ammonia (NH3). As an example, a showerhead-type 3×2" MOCVD reactor commercialized by AIXTRON, may be used. A molecular flow ratio between trimethylgallium and ammonia within the 5-200 range, preferably within the 10-100 range, enables to promote the growth of wires. As an example, a carrier gas which ensures the diffusion of organometallic elements all the way to the reactor charges with organometallic elements in a TMGa bubbler. The latter is set according to the standard operating conditions. A flow of 60 sccm (standard cubic centimeters per minute) is for example selected for TMGa, while a 300-sccm flow is used for NH3 (standard NH3 bottle). A pressure of approximately 800 mbar (800 hPa) is used. The gaseous mixture further comprises silane injected into the MOCVD reactor, which material is a precursor of silicon. The silane may be diluted in hydrogen at 1,000 ppm and a 20-sccm flow is provided. The temperature in the reactor is for example in the range from 950° C. and 1,100° C., preferably from 990° C. to 1,060° C. To transport species from the outlet of the bubblers to the two reactor plenums, a 2,000-sccm flow of carrier gas, for example, N2, distributed between the two plenums, is used. The previously-indicated gas flows are given as an indication and should be adapted according to the size and to the specificities of the reactor.

The presence of silane among the precursor gases results silicon being incorporated within the GaN compound. A lower N-type doped portion **28** is thus obtained. This further translates as the forming of a silicon nitride layer, not shown, which covers the periphery of portion **28** of height H**2**, except for the top, as portion **28** grows.

(4) Growing upper portion **30** of height H**3** of each wire **26** on the top of lower portion **28**. For the growth of upper portion **30**, the previously-described operating conditions of the MOCVD reactor are, as an example, maintained but for the fact that the silane flow in the reactor is decreased, for example, by a factor greater than or equal to 10, or stopped. Even when the silane flow is stopped, upper portion **30** may be N-type doped due to the diffusion in this active portion of dopants originating from the adjacent passivated portions or due to the residual doping of GaN.

(5) Forming by epitaxy, for each wire **26**, the layers forming shell **34**. Given the presence of the silicon nitride layer covering the periphery of lower portion **28**, the deposition of the layers forming shell **34** only occurs on upper portion **30** of wire **26**.

(6) Forming insulating layer **32**, for example, by conformally depositing an insulating layer over the entire structure obtained at step (5) and etching this layer to expose shell **34** of each wire **26**. In the previously-described embodiment, insulating layer **32** does not cover shell **34**. As a variation, insulating layer **32** may cover a portion of shell **34**. Further, insulating layer **32** may be formed before shell **34**.

(7) Forming electrode **36**, for example, by conformal deposition.

(8) Forming conductive layer **38**, for example, by physical vapor deposition (PVD) over the entire structure obtained at step (7) and etching this layer to expose each wire **26**. FIG. **2**B shows the structure obtained after having deposited an encapsulation layer **40** over the entire wafer **10**. The maximum thickness of encapsulation layer **40** is in the range from 12 μm to 1,000 μm, for example, approximately 50 μm, so that encapsulation layer **40** totally covers electrode **36** at the top of light-emitting diodes DEL. Encapsulation layer **40** is made of an at least partially transparent insulating material.

Encapsulation layer **40** may be made of an at least partially transparent inorganic material.

As an example, the inorganic material is selected from the group comprising silicon oxides, of type SiOx where x is a real number between 1 and 2, or SiOyNz where y and z are real numbers between 0 and 1, and aluminum oxides, for example, Al2O3. The inorganic material may then be deposited by low-temperature CVD, particularly at a temperature lower than 300° C.-400° C., for example by PECVD (plasma enhanced chemical vapor deposition).

Encapsulation layer **40** may be made of an at least partially transparent organic material. As an example, encapsulation layer **40** is a silicone polymer, an epoxide polymer, an acrylic polymer, or a polycarbonate. Encapsulation layer **40** may then be deposited by a spin coating method, by an inkjet printing method, or by a silk-screening method. A method of dispensing by time pressure dispenser or by volumetric dispenser is also possible in automated mode on programmable equipment.

FIG. 2C shows the structure obtained after attaching an additional support 42, called handle, on encapsulation layer 40. As an example, the handle has a thickness in the range from 200 μm to 1,000 μm.

According to an embodiment, handle 42 is intended to be kept on the optoelectronic devices once sawn. Handle 42 then is made of an at least partly transparent material. It may be glass, particularly a borosilicate glass, for example, Pyrex, or sapphire. An observer perceives the light rays emitted by light-emitting diodes DEL which cross surface 43 of handle 42 opposite to encapsulation layer 40.

According to another embodiment, handle 42 is intended to be removed at a subsequent step of the manufacturing method. In this case, handle 42 may be made of any type material compatible with the subsequent steps of the manufacturing method. It may be silicon or any planar substrate compatible with microelectronics flatness criteria.

Handle 42 may be attached to encapsulation layer 40 by any means, for example, by bonding, for example by using a layer of organic temperature-crosslinkable glue, not shown, or also by molecular bonding (direct bonding) or optical bonding with UV-cured glue. When encapsulation layer 40 is made of an organic material, this material may be used as glue for handle 42. When a glue layer is used, it should be at least partially transparent.

FIG. 2D shows the structure obtained after a step of thinning substrate 10. After thinning, the thickness of substrate 10 may be in the range from 20 μm to 200 μm, for example, approximately 30 μm. The thinning step may be carried out by one or more than one milling or etching step, and or by chemical mechanical polishing methods (CMP). Thinned substrate 10 comprises a surface 44 opposite to surface 22. Surfaces 22 and 44 are preferably parallel.

FIG. 2E shows the structure obtained after the steps of:

forming an insulating layer 45, for example, made of silicon oxide (SiO2) or of silicon oxynitride (SiON), on the rear surface of substrate 10. Insulating layer 45 is for example carried out by conformal deposition by PECVD;

etching, for each optoelectronic device, at least one opening 46 crossing insulating layer 45, substrate 10, insulating layer 32, and electrode 36 to expose a portion of metal layer 38. The etching of substrate 10 may be a deep reactive ion etching (DRIE). The etching of the portion of insulating layer 32 is also performed by plasma etching with the chemistry adapted to insulating layer 32. At the same time, electrode layer 36 may be etched. As a variation, layer 36 may be removed from the areas where vias 46 are formed before the step of forming metal layer 38. Opening 46 may have a circular cross-section. The diameter of opening 46 may then be in the range from 5 μm to 200 μm according to the size of unit optoelectronic component 14 such as shown in FIG. 1, for example, approximately 15 μm. A plurality of circular openings 46 may then be simultaneously formed to create connections in parallel. This enables to decrease the resistance of connections. Such connections may be arranged at the periphery of the area where light-emitting diodes DEL are formed. As a variation, opening 46 may correspond to a trench, for example extending along at least one side of the optoelectronic device. Preferably, the trench width is in the range from 15 μm to 200 μm according to the size of unit optoelectronic component 14 such as shown in FIG. 1, for example, approximately 15 μm;

forming an insulating layer 48, for example, made of SiO2 or SiON, on the internal walls of opening 46 and, possibly on layer 45, the portion of layer 48 covering layer 45 not being shown in the drawings. Insulating layer 48 is for example formed by conformal PECVD. Insulating layer 48 has a thickness in the range from 200 nm to 5,000 nm, for example, approximately 3 μm;

etching insulating layer 48 to expose conductive layer 38 at the bottom of opening 46. This etching is anisotropic; and

etching at least one opening 50 in insulating layer 45 to expose a portion of surface 44 of substrate 10. To perform this etching, opening 46 may be temporarily obstructed, for example, with a resin.

FIG. 2F shows the structure obtained after the forming of a second electrode 52 in opening 50 and of a conductive layer 54 on insulating layer 48, conductive layer 54 covering the internal walls of opening 46 to come into contact with metal portion 36, and extending on surface 44 around opening 46. Electrode 52 and conductive layer 54 may comprise a stack of two layers, as shown in the drawings, or more than two layers. It for example is TiCu or TiAl. This layer may be covered with another metal layer, for example, gold, copper, or eutectic alloys (Ni/Au or Sn/Ag/Cu) to implement a soldering method. Second electrode 52 and conductive layer 54 may be formed, particularly in the case of copper, by electrochemical deposition (ECD). The thickness of electrode layer 52 and conductive layer 54 may be in the range from 1 μm to 10 μm, for example, approximately 5 μm.

The assembly comprising opening 46, insulating layer 48, and conductive layer 54 forms a vertical connection 56 or TSV (Through Silicon Via). Vertical connection 56 enables to bias first electrode 36 from the rear surface of substrate 10 while the biasing of wires 26 is obtained by second electrode 52 through substrate 10.

FIGS. 3A and 3B are partial simplified cross-section views of structures obtained at successive steps of another embodiment of a method of manufacturing optoelectronic devices with wires, which comprises all the steps described in relation with FIGS. 2A to 2E.

FIG. 3A shows the structure obtained after the steps of:

forming in opening 50 of insulating layer 44 a conductive pad 60;

depositing an insulating layer 62 particularly covering metal pad 60. Insulating layer 62 may be made of silicon oxide or of silicon nitride or may correspond to a stack of two stacked layers or more and have a thickness in the range from 200 nm to 1,000 nm; and

etching openings 64 in insulating layer 62 to expose portions of conductive pad 60.

FIG. 3B shows the structure obtained after steps similar to what has been previously described in relation with FIG. 2F to form second electrodes 66 in openings 64 and conductive layer 54 in opening 46.

The embodiment described in relation with FIGS. 3A and 3B advantageously enables to adjust the positions and the dimensions of second electrodes 66.

FIG. 4 illustrates another embodiment of a manufacturing method comprising, after the steps previously described in relation with FIG. 2F, the steps of:

depositing an insulating layer 68 particularly covering pad 52 and filling opening 46. It may be an insulating polymer, for example, a BCB (benzocyclobutene) resist having a thickness in the range from 2 μm to 20 μm, or a silicon oxide, or silicon nitride, or both, and have a thickness in the range from 200 nm to 1,000 nm;

forming openings 70 in insulating layer 68 to expose portions of second electrode 52 and conductive layer

54. It may be a plasma-type etching when insulating layer **68** is made of an inorganic material or steps of illumination and development when insulating layer **68** is made of a resist; and
forming conductive bumps **72** in openings **70**. Bumps **72** are made of materials compatible with soldering operations in electronics, for example tin- or gold-based alloys. Bumps **72** may be used to attach the optoelectronic device to a support, not shown.

In the previously-described embodiments, the current flows between first electrode **36** and second electrode **52**, **66** through substrate **10**.

FIG. **5** illustrates another embodiment where the light-emitting diodes are directly biased at the base of wires **26**. Wires **26** are formed on a seed layer **74**, which is then common to an assembly of light-emitting diodes DEL of the optoelectronic device. A vertical connection **76** is formed in substrate **10**, for example, similarly to vertical connection **56**, with the difference that vertical connection **76** is connected to seed layer **74**.

FIGS. **6**A to **6**C are partial simplified cross-section views of structures obtained at successive steps of another embodiment of a method of manufacturing optoelectronic devices with wires which comprises all the steps described in relation with FIGS. **2**A to **2**E.

FIG. **6**A shows the structure obtained after the deposition of a thick metal layer **80**, for example, copper. It may be an ECD. The thickness of insulating layer **80** is for example in the order of 10 μm. Metal layer **80** is sufficiently thick to fill opening **46**.

FIG. **6**B shows the structure obtained after a step of polishing metal layer **80** to delimit a metal portion **82** in opening **50** and a metal portion **84** in opening **46**. The step of planarizing layer **80** may be carried out by CMP.

FIG. **6**C shows the structure after steps similar to those previously described in relation with FIGS. **3**A and **3**B, comprising depositing an insulating layer **86** over the entire rear surface of substrate **10** and forming a second electrode **88** crossing layer **86** in contact with metal portion **82** and a conductive pad **90** crossing layer **86** in contact with metal portion **84**. A passivation layer, particularly made of polymer, may be deposited on the structure on the rear surface side, openings being formed in the passivation layer to expose electrode **88** and conductive pad **90**.

The assembly comprising opening **46**, insulating layer **48**, metal portion **84**, and metal pad **90** forms a TSV **91** which plays the same role as previously-described TSV **56**. Metal pads **88** and **90** are used to assemble the optoelectronic component encapsulated on its final support, for example, a printed circuit. The assembly methods may be carried out by soldering. The metal stack is selected to be compatible with solder operations used in electronics, and particularly with the soldering used, for example, in Cu with an organic solderability preservative finish (OSP) or Ni—Au finish (by a process which may be chemical (ENIG, Electroless nickel immersion gold) or electrochemical), Sn, Sn—Ag, Ni—Pd—Au, Sn—Ag—Cu, Ti—Wn-Au, or ENEPIG (Electroless Nickel/Electroless Palladium Immersion Gold).

FIGS. **7**A and **7**B are partial simplified cross-section views of structures obtained at successive steps of another embodiment of a method of manufacturing optoelectronic devices with wires.

The initial steps may comprise the steps previously described in relation with FIG. **2**A, with the difference that, before steps (5) to (7), an opening **92** is formed in substrate **10**. Opening **92** may be formed by a DRIE-type etching. The depth of opening **92** is strictly greater than the thickness of substrate **10** after the thinning step. As an example, the depth of opening **92** is in the range from 10 μm to 200 μm, for example, in the order of 35 μm.

During the implementation of steps (5) to (7), insulating layer **32**, electrode **36**, and conductive layer **38** are also formed in opening **92**.

FIG. **7**B shows the structure obtained after the carrying out of the steps of:
depositing encapsulation layer **40** similarly to what has been previously described in relation with FIG. **2**B. Encapsulation layer **40** partially or totally penetrates into opening **92**;
installing handle **42** similarly to what has been previously described in relation with FIG. **2**C;
thinning substrate **10** similarly to what has been previously described in relation with FIG. **2**D all the way to opening **92**;
forming an insulating layer **94** on rear surface **44** of substrate **10** while protecting opening **92**; and
forming an opening **96** in insulating layer **94** to expose a portion of substrate **10**.

The assembly comprising opening **92** and the portions of insulating layer **32**, of electrode layer **36**, and of conductive layer **38** extending in opening **92** forms a TSV **98** which plays the same role as previously-described TSV **56**.

The subsequent steps of the method may be similar to what has been previously described in relation with FIG. **2**F.

FIG. **8** shows an embodiment where substrate **10** is at least sawn once at the level of a TSV which may correspond to one of previously-described TSVs **56**, **91**, or **98**. The sawing exposes a portion of the conductive layer which extends on the internal walls of the TSV. The biasing of first electrode **36** of light-emitting diodes DEL may then be performed from the side of the optoelectronic device. As an example, the optoelectronic device may be attached to a support **100** by a connection pad **102** in contact with the rear surface of substrate **14** and by a connection pad **104** in contact with the lateral exposed portion of the TSV.

FIG. **9** shows an embodiment where a TSV **106** is provided at the level of each wire **26** of the optoelectronic device. Each TSV **106** comes into contact with seed pad **24** of the associated wire **26**. TSVs **106** may be unconnected to one another. Wires **26** can then be separately biased. As a variation, an electrode, not shown, provided on the side of rear surface **44** of substrate **10**, may be connected to all the vertical connections **106** associated with a same optoelectronic device.

FIG. **10** shows an embodiment where a TSV **110** simultaneously comes into contact with seed pads **24** of a plurality of wires **26**. Vertical connections **106**, **110** may be formed according to any of the manufacturing methods previously described for the forming of TSVs **56**, **91**, and **98**.

FIGS. **11**A to **11**D are partial simplified cross-section views of structures obtained at successive steps of another embodiment of a method of manufacturing optoelectronic devices with wires.

FIGS. **11**A and **11**B show structures obtained after the carrying out of steps before step (1) previously described in relation with FIG. **2**A.

FIG. **11**A shows the structure obtained after the steps of:
etching an opening **120** in substrate **10**. Opening **120** may be formed by an etching of reactive ion etching type, for example, a DRIE etching. The depth of opening **120** is strictly greater than the targeted thickness of substrate **10** after the thinning step. As an example, the depth of opening **120** is in the range from 10 μm to 200 μm, for example, approximately 35 μm. The distance

between the lateral walls of opening **120** is in the range from 1 to 10 μm and for example 2 μm; and

forming an insulating portion **122**, for example, made of silicon oxide, on the lateral walls of opening **120**, for example, by a thermal oxidation method. At this step, an insulating portion may also form at the bottom of opening **120** and on the rest of substrate **10**. The thickness of insulating portion may be in the range from 100 nm to 3,000 nm, for example, approximately 200 nm.

FIG. **11**B shows the structure obtained after carrying out the steps of:

anisotropically etching the insulating portion at the bottom of opening **120** and the insulating portion covering surface **22** of substrate **10**, to keep insulating portions **122** on the lateral sides of opening **120**. As an example, the etching of the insulating portion covering surface **22** of substrate **10** may be omitted. In this case, a mask formed by photolithography may be provided to protect said unetched insulating portions;

filling opening **120** with a filling material, for example, polysilicon, tungsten, or a refractory metallic material which supports the thermal budget during the previously-described steps carried out a high temperatures, particularly in relation with steps 2A to 2D, for example, deposited by LPCVD. Polysilicon advantageously has a thermal expansion coefficient close to that of silicon and thus enables to decrease the mechanical stress during the previously-described steps carried out at high temperatures, particularly in relation with steps 2A to 2D;

removing the layer of filling material, for example, by a CMP-type method. In the case where the etching of the insulating portion covering surface **22** of substrate **10** has been omitted during the anisotropic etching of the insulating portion at the bottom of opening **122**, said unetched layer may advantageously be used as a stop layer during the removal of the layer of filling material. In this case, the removal of the layer of filling material is followed by a step of etching the insulating portion covering surface **22** of substrate **10**. A portion **124** of the filling material is thus obtained.

FIG. **11**C shows the structure obtained after the implementation of steps similar to what has been previously described in relation with FIGS. **2**A to **2**D, with the difference that it comprises, before the forming of conductive layer **38**, a step of etching an opening **125** in electrode layer **36** and of insulating layer **32** so that conductive layer **38** comes into contact with portion **124**.

FIG. **11**D shows the structure obtained after implementation of the following steps, similarly to what has been previously described in relation with FIGS. **7**B, **3**A, and **3**B:

thinning substrate **10** to reach conductive portion **124**;

forming an insulating layer **126** on rear surface **44** of substrate **10**;

forming, in insulating layer **126**, an opening **128** to expose a portion of rear surface **44** of substrate **10** and an opening **130** to expose conductive portion **124**;

forming a conductive pad **132** in opening **128** in contact with substrate **10** and with a conductive pad **134** in opening **130** in contact with conductive portion **124**;

forming an insulating layer **136** covering insulating layer **126** and conductive pads **132**, **134**;

forming, in insulating layer **136**, an opening **138** to expose a portion of conductive pad **132** and an opening **140** to expose conductive pad **134**; and

forming a second electrode **142** in opening **138** in contact with conductive pad **132** and a conductive pad **144** in opening **130** in contact with conductive pad **134**.

The assembly comprising portion **124** of the filling material delimited by insulating portions **122** forms a TSV **145** which plays the same role as previously-described TSV **56**. Conductive portion **124** which connects pad **144** to metal layer **38** is formed by portion **124** of the filling material.

As a variation, insulating layer **126** may be absent and conductive pads **132**, **144** may be directly formed on substrate **10**.

According to another variation, instead of forming a portion **124** of a filling material insulated from substrate **10** by insulating portions, the method may comprise steps of forming insulating trenches delimiting a portion of the substrate which then plays the role of portion **124**. Preferably, heavily-doped silicon, for example having a dopant concentration greater than or equal to 1019 atoms cm3, is used to decrease the resistance of this connection. This conductive portion may be formed by one or a plurality of silicon trenches around the active area or by one or a plurality of insulated silicon vias.

The embodiment previously described in relation with FIGS. **11**A to **11**D may be implemented to form vertical connections **106** and **110** previously described in relation with FIGS. **9** and **10**.

FIGS. **12**A to **12**E are partial simplified cross-section views of structures obtained at successive steps of another embodiment of a method of manufacturing optoelectronic devices with wires. The initial steps may comprise the steps previously described in relation with FIGS. **2**A to **2**C, with the difference that conductive layer **38** is not present.

FIG. **12**A shows the structure obtained after a step of removing substrate **10**. The removal of substrate **10** may be performed by one or more than one etch step. The rear surface of the structure thus exposed after removal of the substrate is designated with reference numeral **150**. In FIG. **12**A, the etching is stopped on insulating layer **32** and on seed pads **24**. As a variation, the method may further comprise removing seed pads **24**.

FIG. **12**B shows the structure obtained after carrying out the steps of:

etching an opening **152** in insulating layer **32**;

depositing a mirror layer **154** on rear surface **150** and in opening **152**; and

depositing a conductive layer **156** covering mirror layer **154**.

Mirror layer **154** may be a single layer or correspond to a stack of two layers or of more than two layers. As an example, mirror layer **154** corresponds to a metal monolayer. According to another example, mirror layer **154** corresponds to a stack of layers comprising a metal layer covered with a dielectric layer or with a plurality of dielectric layers. The metal layer of mirror layer **154** may be formed on a bonding layer, for example, made of titanium. The thickness of mirror layer **154** (monolayer or multilayer) is greater than 15 nm, for example, in the range from 30 nm to 2 μm. Mirror layer **154** may be deposited by ECD.

According to an embodiment, mirror layer **154** is capable of at least partly reflecting the radiation emitted by light-emitting diodes DEL.

According to an embodiment, the complex optical indexes of the materials forming seed pads **24** and mirror layer **154** (monolayer or multilayer) and the thicknesses of seed pads **24** and of mirror layer **154** are selected to increase the mean reflectivity of seed pads **24** and mirror layer **154**. The mean reflectivity of a layer or of a stack of layers is the

mean of the ratio of the electromagnetic energy reflected by the layer or the stack of layers to the incident energy for all possible angles of incidence at a given wavelength. It is desirable for the mean reflectivity to be as high as possible, preferably greater than 80%.

The complex optical index, also called complex refraction index, is a dimensionless number which characterizes the optical properties of a medium, particularly the absorption and the diffusion. The refraction index is equal to the real part of the complex optical index. The extinction coefficient, also called attenuation coefficient, measures the energy loss of an electromagnetic radiation crossing this material. The extinction coefficient is equal to the opposite of the imaginary part of the complex refraction index. The refraction index and the extinction coefficient of a material may be determined, for example, by ellipsometry. A method of analyzing ellipsometric data is described in the work entitled "Spectroscopic ellipsometry, Principles and Applications" by Hiroyuki Fujiwara, published by John Wiley & Sons, Ltd (2007).

As an example, the material forming the metal layer of mirror layer **154** (monolayer or multilayer) may be aluminum, silver, chromium, rhodium, ruthenium, palladium, or an alloy of two of these compounds or of more than two of these compounds.

According to an embodiment, the thickness of each seed pad **24** is smaller than or equal to 20 nm.

According to an embodiment, the refractive index of each seed pad **24** is in the range from 1 to 3 for a wavelength in the range from 380 nm to 650 nm.

According to an embodiment, the extinction coefficient of each seed pad **24** is smaller than or equal to 3 for a wavelength in the range from 380 nm to 650 nm.

As an example, the material forming each seed pad **24** may correspond to the previously-indicated examples.

Conductive layer **156** may be made of aluminum, of silver, or of any other conductive material. As an example, it has a thickness in the range from 30 nm to 2,000 nm. Conductive layer **156** may be deposited by ECD. Mirror layer **154** and conductive layer **156** may be confounded.

FIG. **12**C shows the structure obtained after a step of etching conductive layer **156** and mirror layer **154** to delimit a pad **158**, comprising a portion **160** of mirror layer **154** and a portion **162** of conductive layer **156**, connected to electrode layer **36** and a pad **164**, comprising a portion **166** of mirror layer **154** and a portion **168** of conductive layer **156**, connected to seed pads **24**.

FIG. **12**D shows the structure obtained after the steps of:

depositing an insulating layer **170** extending on pads **158**, **164** and between pads **158**, **164**;

etching, in insulating layer **170**, an opening **172** exposing conductive pad **158** and an opening **174** exposing conductive pad **164**; and

depositing a conductive layer **176** covering insulating layer **170** and penetrating into openings **172**, **174**.

Insulating layer **170** may be made of silicon dioxide deposited by low-temperature PECVD or an organic material of BCB, Epoxy type having a thickness of a few microns, typically 3-5 μm.

Conductive layer **176** may be made of TiCu or TiAl. As an example, it has a thickness in the range from 500 nm to 2 μm.

FIG. **12**E shows the structure obtained after a step of etching conductive layer **176** to delimit a conductive pad **178** connected to conductive pad **158**, a second electrode **180** connected to conductive pad **164**, and a conductive portion **182** in contact with insulating layer **170**. Conductive portion **182** may play the role of a radiator. Insulating layer **170** may particularly enable to electrically insulate heat sink **182** from electric contact pad **158** and/or from conductive layer **156**.

The embodiment described in relation with FIGS. **12**A to **12**E has the advantage of suppressing the series resistance due to substrate **10**.

FIGS. **13** and **14** respectively are a cross-section view and a top view, partial and simplified, of an embodiment of an optoelectronic device **190** with wires formed on a wafer **10** of a substrate after the step of thinning substrate **10** and before the sawing of substrate **10**. In FIG. **13**, optoelectronic devices **192** adjacent to optoelectronic device **190** have further been partially shown.

Each optoelectronic device **190**, **192** is surrounded with one or a plurality of trenches **194** (two in the present example) filled with an insulating material, which extend across the entire thickness of thinned substrate **10**. As an example, each trench has a width greater than 1 μm, for example, approximately 2 μm. The distance between the two trenches **194** is greater than 5 μm, for example, approximately 6 μm. The sawing lines of substrate **10**, shown by short-dashed lines **196**, are formed between trenches **194** of optoelectronic device **190** and trenches **194** of the adjacent optoelectronic devices **192**. Trenches **194** provide a lateral electric insulation of the silicon substrate and thus of optoelectronic device **190** after sawing.

As shown in FIG. **14**, additional trenches **198** connect the external trenches **194** of two adjacent optoelectronic devices **190**, **192**. After the sawing, a portion **200** of substrate **10** remains at the periphery of each optoelectronic device **190**, **192**. Trenches **198** enable to divide peripheral portion **200** into a plurality of insulated segments **202**. This enables to decrease short-circuit risks in the case where conductive pads would come into contact with these segments.

According to an embodiment, the optoelectronic device further comprises phosphors capable, when they are excited by the light emitted by the light-emitting diodes, of emitting light at a wavelength different from the wavelength of the light emitted by the light-emitting diodes. As an example, the light-emitting diodes are capable of emitting blue light and the phosphors are capable of emitting yellow light when they are excited by blue light. Thereby, an observer perceives a light corresponding to a composition of the blue and yellow lights which, according to the proportion of each light, may be substantially white. The final color perceived by the observer is characterized by its chromatic coordinates such as defined by the standards of the International Committee on Illumination.

According to an embodiment, a layer of phosphors is provided within encapsulation layer **40**. Preferably, the mean diameter of the phosphors is selected so that at least part of the phosphors distribute between wires **26** during the step of forming encapsulation layer **40**. Preferably, the phosphors have a diameter in the range from 45 nm to 500 nm. The phosphor concentration and the thickness of the phosphor layer are then adjusted according to the targeted chromatic coordinates.

The extraction ratio of an optoelectronic device is generally defined by the ratio of the number of photons escaping from the optoelectronic device to the quantity of photons emitted by the light-emitting diodes. Each light-emitting diode emits light in all directions, and particularly towards the neighboring light-emitting diodes. The active layer of a light-emitting diode tends to capture photons having a wavelength smaller than or equal to the transmission wavelength. Thereby, part of the light emitted by a light-emitting

diode is generally captured by the active layers of the neighboring light-emitting diodes. An advantage of arranging phosphors between wires **26** is that the phosphors convert part of the light, for example, blue, emitted by a light-emitting diode into a light at a higher wavelength, for example, yellow, before the blue light reaches the neighboring light-emitting diodes. Since yellow light is not absorbed by the active layers of the neighboring light-emitting diodes, the extraction ratio of the optoelectronic device is increased.

Another advantage is that since the phosphors are located close to substrate **10**, the discharge by the substrate of the heat generated during the heating of the phosphors in operation is improved.

Another advantage is that since the phosphors are not arranged in a separate layer, the total thickness of the optoelectronic device is decreased.

Another advantage is that the homogeneity of the light emitted by the optoelectronic device is improved. Indeed, the light which escapes from encapsulation layer **40** in all directions corresponds to a composition of the light emitted by the light-emitting diodes and of the light emitted by the phosphors.

FIG. **15** shows an embodiment of an optoelectronic device **205** comprising all the elements shown in FIG. **2**F and further comprising, between encapsulation layer **40** and handle **42**, a layer of phosphors **206** extending on encapsulation layer **40** and possibly a layer of glue **208** extending of phosphor layer **206**, handle **42** extending on glue layer **208**. The thickness of phosphor layer **206** may be in the range from 50 μm to 100 μm. Phosphor layer **206** may correspond to a layer of silicone or of an epoxide polymer having the phosphors embedded therein. Phosphor layer **206** may be deposited by a spin coating method, by an inkjet printing method, or by a silk-screening method or by a sheet deposition method. The phosphor concentration and the thickness of phosphor layer **206** are adjusted according to the targeted chromatic coordinates. As compared with the embodiment where the phosphors are present in encapsulation layer **40**, phosphors of larger diameter may be used. Further, the phosphor distribution in phosphor layer **206** and the thickness of phosphor layer **206** may be more easily controlled.

FIG. **16** shows an embodiment of an optoelectronic device **210** comprising all the elements of optoelectronic device **205** shown in FIG. **15**, with the difference that phosphor layer **206** covers handle **42**. A protection layer, not shown, may cover phosphor layer **206**. In the present embodiment, phosphor layer **206** is advantageously formed in the last steps of the optoelectronic device manufacturing method. The colorimetric properties of the optoelectronic device may thus further be modified during the most part of the optoelectronic device manufacturing method. Further, the colorimetric properties of the optoelectronic device may easily be corrected at the end of the process if necessary by modifying the phosphor layer, for example, by adding an additional phosphor layer.

FIG. **17** shows an embodiment of an optoelectronic device **215** comprising all the components of optoelectronic device **210** shown in FIG. **16** and further comprising trenches **216** extending in handle **42** and filled with phosphor layer **206**. Preferably, trenches **216** extend across the entire thickness of handle **42**. The distance between the lateral walls of each trench **216** is preferably substantially equal to the thickness of phosphor layer **206** covering handle **42**.

For optoelectronic device **210**, shown in FIG. **16**, part of the light emitted by light-emitting diodes DEL may escape from the lateral edges of handle **42** without having crossed phosphor layer **206**. The color of the laterally-escaping light is thus different from the color of the light having crossed phosphor layer **206**, which may not be desirable if a light of homogeneous color is desired. For optoelectronic device **215**, the light laterally escaping from handle **42** crosses trenches **216** filled with phosphor layer **206**. The light escaping from handle **42**, through surface **43** or laterally, thus advantageously has a homogeneous color.

FIG. **18** shows an embodiment of an optoelectronic device **220** comprising all the elements of optoelectronic device **205** shown in FIG. **15**, with the difference that glue layer **208** is not shown and that an intermediate layer **222** is interposed between encapsulation layer **40** and phosphor layer **206**.

Intermediate layer **222** is capable of letting through the light rays emitted by light-emitting diodes DEL at a first wavelength or in a first wavelength range and of reflecting the light rays emitted by the phosphors at a second wavelength or in a second wavelength range. The extraction ratio of optoelectronic device **220** is then advantageously increased. As an example, intermediate layer **222** may correspond to a dichroic mirror, which is a mirror reflecting light rays having a wavelength within a certain range and letting through light rays having a wavelength which does not belong to this range. A dichroic mirror may be formed of a stack of dielectric layers having different optical indexes.

According to another example, intermediate layer **222** may be a monolayer made of a material having a refractive index smaller than the refractive index of encapsulation layer **40** and smaller than the refractive index of the phosphor layer. Intermediate layer **222** may correspond to a silicone or epoxide polymer layer. Further, a surface treatment, called texturing, is applied to surface **224** of encapsulation layer **40** before the forming of intermediate layer **222** to form raised areas on surface **224**. Interface **226** between intermediate layer **222** and phosphor layer **206** is substantially planar. The light rays emitted by light-emitting diodes DEL cross interface **224** which is irregular even if the refractive index of intermediate layer **222** is smaller than the refractive index of encapsulation layer **40** while the light rays emitted by the phosphors mainly reflect on interface **226**, given that interface **226** is planar and that the refractive index of intermediate layer **222** is smaller than the refractive index of phosphor layer **206**.

A texturing method causing the forming of raised areas at the surface may be applied to free surface **43** of handle **42** and or to surface **228** of phosphor layer **206** in contact with handle **42**.

For a layer made of an inorganic material, the method of texturing a surface of the layer may comprise a chemical etching step or a mechanical abrasion step, possibly in the presence of a mask protecting portions of the treated surface in order to promote the forming of raised areas at the surface. For a layer made of an organic material, the method of texturing a surface of the layer may comprise a step of embossing, moulding, etc.

For the previously-described optoelectronic devices, part of the light emitted by light-emitting diodes DEL may escape through the lateral edges of encapsulation layer **40**. This is generally not desirable since this light is not perceived by an observer in normal operating conditions of the optoelectronic device. According to an embodiment, the optoelectronic device further comprises means capable of reflecting the light rays laterally escaping from the optoelectronic device to increase the quantity of light escaping from surface **43** of handle **42**.

FIG. **19** shows an embodiment of an optoelectronic device **230** comprising all the components of the optoelectronic device shown in FIG. **2**F and further comprising blocks **232** arranged on insulating layer **32** and at least partially surrounding the assembly of light-emitting diodes DEL. Each block **232** is covered with a metal layer **234**, for example corresponding to an extension of conductive layer **38**. As an example, blocks **232** may correspond to resist blocks formed on insulating layer **32** before the deposition of encapsulation layer **40**. Preferably, the height of blocks **232** is smaller than the maximum height of encapsulation layer **40**. In FIG. **19**, lateral edges **236** of blocks **232** are substantially perpendicular to surface **22** of substrate **10**. As a variation, lateral sides **236** may be inclined with respect to surface **22** to promote the reflection of light rays towards surface **43** of handle **42**.

FIG. **20** shows an embodiment of an optoelectronic device **240** comprising all the components of the optoelectronic device shown in FIG. **2**F and further comprising blocks **242** arranged on insulating layer **32** and at least partially surrounding the assembly of light-emitting diodes DEL. Blocks **242** are made of a reflective material. It may be silicone filled with reflective particles, for example, titanium oxide particles (TiO_2). As an example, blocks **242** may be formed on insulating layer **32** by a silk-screening method before the deposition of encapsulation layer **40**. Preferably, the height of blocks **242** is smaller than the maximum height of encapsulation layer **40**. In FIG. **20**, lateral edges **244** of blocks **242** are substantially perpendicular to surface **22** of substrate **10**. As a variation, lateral edges **244** may be inclined with respect to surface **22** to promote the reflection of light rays towards surface **43** of handle **42**.

FIG. **21** shows an embodiment of an optoelectronic device **245** comprising all the components of the optoelectronic device shown in FIG. **2**F, with the difference that light-emitting diodes DEL are formed in a cavity **246** formed in substrate **10**. Lateral sides **248** of cavity **246** are covered with an insulating layer **250**, for example corresponding to an extension of insulating layer **32**, and with a metal layer **252**, for example corresponding to an extension of conductive layer **38**. Preferably, the depth of cavity **246** is smaller than the maximum height of encapsulation layer **40**. In FIG. **21**, lateral sides **248** of the cavity are substantially perpendicular to surface **43** of handle **42**. As a variation, lateral sides **248** may be inclined with respect to surface **43** to promote the reflection of light rays towards surface **43** of handle **42**.

FIG. **22** shows an embodiment of an optoelectronic device **255** comprising all the components of the optoelectronic device shown in FIG. **2**F and further comprising trenches **256** surrounding light-emitting diodes DEL, a single trench being shown in FIG. **22**. Trenches **256** cross substrate **10** and encapsulation layer **40**. The internal walls of each trench **256** are covered with a reflective layer **258**, for example, a metal layer, for example, made of silver or aluminum or a varnish layer, having a thickness in the range from 30 nm to 2,000 nm. An insulating layer, not shown, may be provided to insulate reflective layer **258** from substrate **10**. Trenches **256** may be formed after the step of thinning substrate **10** previously described in relation with FIG. **2**D. An advantage over optoelectronic devices **230**, **240**, and **245** is that encapsulation layer **40** may be formed on a planar surface, which makes its deposition easier.

FIG. **23** shows an embodiment of an optoelectronic device **260** comprising all the components of the optoelectronic device shown in FIG. **2**F and further comprising trenches **262** formed in encapsulation layer **40** and surrounding light-emitting diodes DEL, a single trench being shown in FIG. **23**. Trenches **262** may be filled with air. Trenches **262** may be formed by etching after the step of forming encapsulation layer **40** in the case where encapsulation layer **40** is made of an inorganic material. Trenches **262** delimit, in encapsulation layer **40**, a central block **264** having the light-emitting diodes embedded therein and peripheral blocks **266** at least partially surrounding central block **264**. Each peripheral block **266** is covered with a metal layer **268**, for example, made of silver or aluminum and having a thickness in the range from 30 nm to 2,000 nm. A glue layer **269** may be provided between handle **42** and blocks **264**, **266**. In FIG. **23**, lateral sides **270** of peripheral blocks **266** are substantially perpendicular to surface **22** of substrate **10**. As a variation, lateral sides **270** may be inclined with respect to surface **22** to promote the reflection of light rays towards surface **43** of handle **42**. An advantage over optoelectronic devices **230**, **240**, and **245** is that encapsulation layer **40** may be formed on a planar surface, which makes its deposition easier.

FIG. **24** shows an embodiment of an optoelectronic device **275** comprising all the components of the optoelectronic device shown in FIG. **2**F and further comprising an insulating layer **276** extending on electrode layer **32** between light-emitting diodes DEL, without covering light-emitting diodes DEL. Insulating layer **276** is covered with a reflective layer **278**. Reflective layer **278** preferably corresponds to a metal layer, for example, made of aluminum, of an aluminum-based alloy, particularly $AlSi_z$, Al_xCu_y (for example, with x equal to 1 and y equal to 0.8%), of silver, gold, nickel, or palladium. As an example, reflective layer **278** has a thickness in the range between 30 nm and 2,000 nm. Reflective layer **278** may comprise a stack of a plurality of layers, particularly comprising a bonding layer, for example, made of titanium. The thicknesses of insulating layer **276** and of reflective layer **278** are selected to that surface **280** of the reflective layer in contact with encapsulation layer **40** is close to the end of shell **34**, for example, less than 1 μm away from the end of shell **34**. As compared with the previously-described embodiments, reflective surface **280** advantageously enables to avoid for light rays emitted by shell **34** of a light-emitting diode DEL to the outside of the light-emitting diode to penetrate into lower portion **28** of the light-emitting diode or lower portions **28** of the neighboring light-emitting diodes. The extraction ratio is thus increased.

FIG. **25** shows an embodiment of an optoelectronic device **285** comprising all the components of optoelectronic device **275** shown in FIG. **24**, with the difference that insulating layer **276** and reflective layer **280** are replaced with a reflective layer **286** extending on electrode layer **32** between light-emitting diodes DEL, without covering light-emitting diodes DEL. It may be a silicone layer filled with reflective particles, for example, TiO_2 particles, or a TiO_2 layer. The thickness of reflective layer **286** is selected so that surface **288** of reflective layer **286** in contact with encapsulation layer **40** is close to the end of shell **34**, for example, less than 1 μm away from the end of shell **34**. The extraction ratio is thus increased.

According to an embodiment, one or a plurality of lenses are provided on surface **43** of handle **42**. The lenses enable to increase the focusing of light rays escaping from surface **43** along the direction perpendicular to surface **43** and thus to increase the quantity of light rays perceived by a user watching surface **43**.

FIG. **26** shows an embodiment of an optoelectronic device **290** comprising all the components of optoelectronic

device **230** shown in FIG. **19**, with the difference that handle **42** is not present. Further, optoelectronic device **290** comprises, for each light-emitting diode DEL, a converging lens **292** arranged on encapsulation layer **40**.

FIG. **27** is a view similar to FIG. **26** of an embodiment **295** where a lens **296** is associated with a plurality of light-emitting diodes DEL.

Specific embodiments of the present invention have been described. Various alterations and modifications will occur to those skilled in the art. Further, although, in the previously-described embodiments, each wire **26** comprises a passivated portion **28** at the base of the wire in contact with one of seed pads **24**, passivated portion **28** may be absent.

Further, although embodiments have been described for an optoelectronic device for which shell **34** covers the top of the associated wire **26** and a portion of the lateral sides of wire **26**, it is possible to only provide the shell at the top of wire **26**.

The invention claimed is:

1. A method of manufacturing optoelectronic devices comprising the steps of:

(a) providing a substrate having a first surface;

(b) forming, on the first surface, assemblies of light-emitting diodes comprising, conical or tapered wire-shaped semiconductor elements;

(c) forming, for each assembly of light-emitting diodes, an electrode layer covering each light-emitting diode of said assembly and a conductive layer covering the electrode layer around the light-emitting diodes of said assembly;

(d) covering the entire first surface of a layer encapsulating the light-emitting diodes;

(e) decreasing the substrate thickness, the substrate having, after step (e), a second surface opposite to the first surface;

(f) forming a conductive element insulated from the substrate and crossing the substrate from the second surface all the way to at least the first surface, the conductive element being in contact with the conductive layer;

(g) after step (d), forming, on the second surface, at least one first conductive pad in contact with the substrate; and

(h) after step (d), cutting the obtained structure to separate each assembly of light-emitting diodes.

2. The method of claim **1**, comprising, at step (f), forming, on the second surface, at least one second conductive pad in contact with the conductive element.

3. The method of claim **1**, comprising forming at least one additional conductive element, insulated from the substrate and crossing the substrate from the second surface all the way to at least the first surface, and in contact with the base of at least one of the light-emitting diodes.

4. The method of claim **1**, wherein the forming of the conductive element successively comprises, after step (e), etching an opening in the substrate from the second surface, forming an insulating layer at least on the lateral walls of the opening, and forming a conductive layer covering the insulating layer, or filling the opening with a conductive material.

5. The method of claim **1**, wherein step (f) is at least partly carried out before step (b) and comprises, before step (b), etching an opening in the substrate from the first surface across a portion of the substrate thickness, the opening being opened on the second surface at step (e).

6. The method of claim **5**, wherein the electrode layer and the conductive layer are further formed in the opening.

7. The method of claim **5**, comprising, before step (b), forming an insulating portion at least on the lateral walls of the opening and filling the opening with a conductive material.

8. The method of claim **1**, comprising, before step (e), a step of attaching a support to the layer encapsulating the light-emitting diodes.

9. The method of claim **1**, wherein the layer encapsulating the light-emitting diodes comprises phosphors between the light-emitting diodes.

10. The method of claim **8**, comprising a step of forming a layer of phosphors covering the layer encapsulating the light-emitting diodes or covering the support.

11. The method of claim **10**, comprising a step of forming a layer, between the layer encapsulating the light-emitting diodes and the phosphor layer, capable of transmitting the light rays emitted by the light-emitting diodes and of reflecting the light rays emitted by the phosphors.

12. The method of claim **1**, comprising a step of forming reflectors around the light-emitting diodes between the substrate and the layer encapsulating the light-emitting diodes and having a height greater by 50% than the height of the light-emitting diodes.
