(57) **ABSTRACT**

Systems and methods for wirelessly recording multi-track audio files. In some aspects, each performer is equipped with a local audio device capable of locally recording the respective performer's audio while also transmitting it to a master recorder. Functions of the local audio device may be adjusted remotely. The locally recorded audio may be used to repair or replace any audio lost or corrupted during transmission to the master recorder. Such repair or replacement may be performed electronically or via playback of the locally recorded audio. In other aspects, a master recorder is not required since all locally recorded audio may be combined or otherwise processed post-recording. Locally recorded audio may include identifiers to aid in post-recording identification of such audio. A multi-memory unit is provided to facilitate manipulation and processing of audio files. A method for automatically adjusting local audio device power mode based upon recorder status is also disclosed.

VIRTUAL WIRELESS MULTITRACK RECORDING SYSTEM

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims the benefit of and is a continuation of the U.S. patent application entitled "Systems and Methods for Remotely Controlling Local Audio Devices in a Virtual Wireless Multitrack Recording System," having Ser. No. 14/808,589, filed Jul. 24, 2015 and currently pending, which is a continuation of the U.S. patent application entitled "Systems and Methods for Remotely Controlling Local Audio Devices in a Virtual Wireless Multitrack Recording System", having Ser. No. 13/530,040, filed Jun. 21, 2012 and issued as U.S. Pat. No. 9,094,636, which is a continuation-in-part of the U.S. patent application entitled "Systems and Methods for Remotely Controlling Local Audio Devices in a Virtual Wireless Multitrack Recording System", having Ser. No. 12/838,164, filed Jul. 16, 2010, and issued as U.S. Pat. No. 8,842,854, which claims the benefit of and is a continuation-in-part of the U.S. patent application entitled "Virtual Wireless Multitrack Recording System", having Ser. No. 11/404,735, filed Apr. 14, 2006, and issued as U.S. Pat. No. 7,929,902, which claims the benefit of and is a continuation-in-part of the U.S. patent application entitled "Virtual Wireless Multitrack Recording System", having Ser. No. 11/181,062, filed Jul. 14, 2005, and issued as U.S. Pat. No. 7,711,443, all of which are incorporated by reference in their entirety as if fully set forth herein.

COPYRIGHT NOTICE

A portion of the disclosure of this patent document contains material, which is subject to copyright protection. The copyright owner has no objection to the facsimile reproduction by anyone of the patent document or the patent disclosure, as it appears in the Patent and Trademark Office patent file or records, but otherwise reserves all copyrights whatsoever.

BACKGROUND OF THE INVENTION

Embodiments of the present invention generally relate to systems and methods for recording and processing audio received from one or more wireless devices. More specifically, the present invention relates to systems and methods for recording and processing audio having one or more tracks received from one or more wireless devices operating in either an asynchronous or synchronous mode.

Many systems and methods have been created to record performance audio. Some such systems include a multi-track audio recorder wired to one or more microphones. Typically, one or more performers performing on a sound stage are recorded by one or more microphones that are directly wired to the multi-track recorder. The multi-track recorder combines the single track of audio received from each microphone to create one multi-track audio file. In many such systems, the received audio and/or the multi-track audio is timestamped with a time reference signal such as a Society of Motion Picture and Television Engineers ("SMPTE") timecode signal containing information regarding the hour, minute, second, frame, type of timecode (i.e., nondrop or drop frame), and user-definable information. Such information allows audio to be more easily matched and/or combined with simultaneously recorded video.

Other such systems include a multi-track audio recorder and an associated audio receiver that receive audio wirelessly from one or more wireless transmitters. Such wireless transmitters may take the form of body packs that are worn by each performer. Typically, the audio receiver receives each performer's audio from the performer's respective body pack via an analog or digital wireless transmission and transmits it to the audio recorder. The audio recorder then combines the wireless transmissions received from all body packs to create one multi-track audio file.

Due to the occurrence of wireless transmission errors such as dropouts, some existing wireless systems include audio receivers having two or more redundant receiver circuits. The incorporation of additional, redundant receiver circuits provides a better opportunity to avoid missed audio transmissions. For example, the use of two receiver circuits may allow a second receiver to receive audio that may have not been received by a first receiver circuit and vice versa. However, although such redundancy accounts may correct wireless transmission errors, such redundancy does not prevent loss of data due to interference (i.e., a distortion of the received audio signal due to receipt of multiple wireless signals). Upon the occurrence of interfering signals, audio created during a performance (e.g., a live performance) may simply be lost due to the inability of the receiver to receive a clean audio signal.

Typically, the quality of audio recorded by an audio recording device is modified within the audio recorder. That is, a user of the audio recorder listens to the received audio and makes various adjustments to the audio recording circuitry to improve the quality thereof. One such adjustment is gain, or amplification, of the received audio. In some such systems, the change in gain or amplification of the audio is made by modifying one or more amplification circuits located in the audio recorder, and these adjustments may be made locally at the audio recorder via knobs, slides, and the like.

BRIEF SUMMARY OF THE INVENTION

Disclosed is a method of dynamically adjusting the power level of at least one local audio device including the steps of: querying a record status of a recorder; generating a power command based upon the record status; transmitting the power command to at least one local audio device; processing of the power command by the at least one local audio device; adjusting at least one local audio device parameter, the parameter selected from the group consisting of RF transmitter bias voltage, RF transmitter source voltage, RF drive levels, and combinations thereof.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

The foregoing summary, as well as the following detailed description of preferred embodiments of the invention, will be better understood when read in conjunction with the appended drawings. For the purpose of illustrating the invention, there are shown in the drawings embodiments that are presently preferred. It should be understood, however, that the invention is not limited to the precise arrangements and instrumentalities shown. In the drawings:

FIG. 1 depicts the components of a recording system in accordance with one embodiment of the present invention including, inter alia, local audio devices, a remote control unit, a receiver, a recorder, and a mixer;

3

FIG. 2A depicts a block diagram of the internal components of a remote control unit in accordance with one embodiment of the present invention;

FIG. 2B depicts an external, front view of a remote control unit in accordance with one embodiment of the present invention;

FIG. 3A depicts a block diagram of the internal components of a local audio device in accordance with one embodiment of the present invention;

FIG. 3B depicts an external, front view of a local audio device in accordance with one embodiment of the present invention;

FIGS. 4A and 4B depict a process for operation of a recording system in a synchronous timecode generator mode in accordance with one embodiment of the present invention;

FIG. 5 depicts a process for modifying the speed of a local timecode generator as necessary to maintain its synchronization with a master timecode generator in accordance with one embodiment of the present invention;

FIG. 6 depicts a process for recording audio and for replaying and re-recording segments of missed audio in accordance with one embodiment of the present invention;

FIG. 7 depicts a process for operation of a recording system in asynchronous timecode generator mode in accordance with one embodiment of the present invention;

FIG. 8 depicts an external view of a multi-memory unit in accordance with one embodiment of the present invention;

FIG. 9 depicts a process for interpolating timestamps for unstamped audio samples based upon the timestamps of stamped audio samples, and resampling the audio samples to include the interpolated timestamps in accordance with one embodiment of the present invention;

FIG. 10 depicts a process for segmenting a single large audio file into multiple smaller files that correlate to a master directory of files in accordance with one embodiment of the present invention;

FIG. 11 depicts a process for generating commands at a recorder;

FIG. 12 depicts a process for receiving commands at one or more local audio devices;

FIG. 13A depicts a block diagram of the internal components of a recorder in accordance with one embodiment of the present invention;

FIG. 13B depicts an external, front view of an exemplary recorder in accordance with one embodiment of the present invention;

FIG. 14 depicts an exemplary format of a data packet in accordance with one embodiment of the present invention;

FIG. 15 depicts exemplary gain adjustment and preamplifier circuit diagrams;

FIG. 16 depicts a process for automatically creating and transmitting high and low power commands used to adjust the power output of one or more local audio devices;

FIG. 17 depicts a process for receiving and processing a low or high power command at a local audio device;

FIG. 18 depicts an exemplary transmitter amplification circuit for use with the processes of FIGS. 16 and 17; and

FIG. 19 depicts a process for automatically creating and transmitting high and low power commands used to adjust the power output of one or more local audio devices in accordance with an alternate embodiment of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

Referring first to FIG. 1, depicted is recording system 100 in accordance with one embodiment of the present inven-

4

tion. Recording system 100 wirelessly records audio events, such as performances, movie takes, etc. having one or more performers. In one aspect of the present invention, all of the components of recording system 100 are synchronized to allow each component to accurately stamp its recorded audio with the time at which it occurred such that the timestamps (i.e., information stored with an audio sample or audio file conveying the time at which the audio sample or first audio sample of the file occurred) created by each individual component of recording system 100 are highly accurate as compared to the timestamps created by all other components of recording system 100. This accuracy allows multiple individually recorded audio tracks to be combined into one or more multi-track audio files electronically post-recording. Furthermore, this accuracy allows recording system 100 to automatically correct for any audio data lost during an original recording due to wireless transmission problems such as dropout, interference, etc. This automatic correction may be performed either electronically or via synchronized playback of the individually recorded audio tracks. In another aspect of the present invention, the audio recorded by recording system 100 may be recorded asynchronously. In this scenario, the audio is synchronized and/or mixed post-recording to automatically correct for any audio data lost due to wireless transmission problems such as dropout, interference, etc.

In the embodiment of the present invention depicted in FIG. 1, recording system 100 includes local audio devices 102, remote control unit ("RCU") 104, receiver 106, and recorder 108. In one embodiment, RCU 104 includes an RF transmitter capable of transmitting one or more of a time reference signal, digital commands, and audio to one or more other components of recording system 100. Additionally, RCU 104 may be equipped with the capability of remotely controlling local audio devices 102, receiver 106, and recorder 108 to perform tasks including, but not limited to, initiating audio playback of all local audio devices 102 starting at the same time reference, as well as recording thereof by receiver 106 and recorder 108.

Both live and replayed audio transmitted by local audio devices 102 may be received at receiver 106 and recorded by audio recorder 108. Receiver 106 and recorder 108 may be virtually any commercially available receiver and recorder. Receiver 106 receives the wireless RF signals (e.g., modulated RF carrier signals) generated by all active local audio devices 102 and converts the signals to a format capable of being recorded by a commercially available recording device including, but not limited to, Zaxcom, Inc.'s DEVA® multi-track recorder. In some embodiments, such commercially available recording devices record audio with a locally generated SMPTE-compatible timecode signal.

The ability to synchronize the local timestamps at each local audio device 102 and recorder 108 using the methods of the present invention as discussed in greater detail below allows any audio that is not recorded by recorder 108 during an event due to transmission errors to be recovered by replaying the missed audio and recording the replayed audio in the correct time sequence with respect to the other audio samples. In other words, since the audio samples are stored locally in each local audio device 102 with timestamps that are synchronized with the timestamps of recorder 108, whenever audio is not recorded at recorder 108, it may simply be replayed at local audio devices 102 starting at the timecode of the missed audio. Since the local audio device and recorder timestamps are synchronized, the replayed audio may be inserted in the proper time sequence with respect to the other recorded audio samples based upon the

synchronized timestamp data. Synchronization is essential to ensure that each performer's audio is synchronized with all other performers' audio and to ensure that the newly recorded replayed audio is in the correct sequence with respect to the previously recorded live audio. Such synchronization must maintain a high accuracy for each performer's timestamps with respect to all other performers' timestamps to prevent the occurrence of phasing artifacts when the multiple audio recordings are combined to create one single recording.

In some embodiments of the present invention, receiver **106** automatically senses an error in transmission caused by, for example, a communication loss, interference, etc. In some embodiments of the present invention, the error in transmission is sensed by comparing a calculated checksum to the transmitted checksum to determine if data was lost during transmission. An error is determined if the calculated and transmitted checksums do not match. Upon sensing a transmission error, receiver **106** may transmit a request to RCU **104** requesting playback of the audio recorded locally on local audio devices **102** beginning at a timecode prior to the occurrence of the transmission error. In response, RCU **104** transmits a digital command to all local audio devices **102** to playback the audio stored in the respective memory **332** (FIG. 3) that occurred subsequent to the timecode requested by receiver **106** in the manner described below with respect to FIG. 6.

Alternatively, playback may be requested manually by a user of a recording system such as recording system **100**. In this scenario, upon hearing that a transmission error (i.e., a loss of audio data) has occurred, the user manually prompts RCU **104** to transmit a digital command to all local audio devices **102** to playback the audio stored in memory **332** (FIG. 3) that occurred subsequent to a time reference entered at RCU **104** by the user. Such prompting may occur after the audio event ends or immediately upon hearing the transmission error. If the latter option is chosen, prompting playback of a specific segment of the audio event may index the local audio devices to store the requested data in a protected memory location until the end of the audio event to avoid disrupting the recording. In this scenario, all requested audio shall be replayed after the performance ends. In embodiments of the present invention in which data is recorded in a loop (i.e., when memory is full, new data overwrites previously recorded data), writing the data to a protected memory location removes it from the loop and protects it from being overwritten.

FIG. 2A depicts a block diagram of one embodiment of RCU **104** in accordance with the present invention. In this embodiment, RCU **104** includes, inter alia, RCU timecode generator **204**, RCU power supply **206**, RCU transmitter **208**, RCU local control unit **210**, RCU audio input device **212**, RCU audio input device port **214**, RCU preamp **216**, RCU display **218**, RCU keypad **220**, RCU ADC **222**, RCU amp **226**, timecode input port **228**, external interface **252**, and external interface port **254**.

RCU transmitter **208** allows RCU **104** to transmit a master time reference signal, digital commands, audio, and the like to other devices such as local audio devices **102**, receiver **106**, and recorder **108**. In one aspect of the present invention, the time reference signal is a SMPTE timecode signal containing information regarding the hour, minute, second, frame, type of timecode (i.e., nondrop or drop frame), and user-definable information (e.g., the transport status of recorder **108**, the name of a scene, the name of a take, a local audio device identifier that identifies the local audio device that recorded the respective audio, a track

identifier that identifies the track of audio which may include the actor or actress recording the respective audio, etc.). This master time reference signal provides a time reference for all local audio devices **102**, which may use this information for a variety of purposes such as jam synchronizing their respective local timecode generators **304** (FIG. 3A), adjusting the speed of the local timecode generators **304** (FIG. 3A), timestamping locally recorded audio, etc. The master time reference signal may be generated on board remote control unit **104** via a mechanism such as RCU timecode generator **204**. Or, alternatively, the master time reference signal may be generated by an independent timecode generator that transmits timecodes to remote control unit **104** wirelessly or via a cable or the like connected from the independent timecode generator to timecode input port **228**. In the latter scenario, the timecodes received via timecode input port **228** are buffered and/or amplified by RCU amp **226** prior to transmission to RCU local control unit **210**.

When recording system **100** is operating in a synchronous mode, transmission of the master time reference signal ensures that all of the components of recording system **100** store all locally recorded audio with timestamps that are highly accurate as compared to the timestamps of all other local audio devices **102** and/or all other components of recording system **100**. The timestamps are then used during playback and recording to ensure that the replayed audio from all local audio devices **102** is synchronized with previously recorded audio and with the audio replayed by all other local audio devices **102**. In contrast, when recording system **100** is operating in an asynchronous mode, transmission of the master time reference signal allows the files containing recorded audio to be timestamped with the master time reference information to allow the recorded audio to be accurately synchronized post-recording.

RCU transmitter **208** also allows audio generated locally at RCU **104** to be transmitted to the other components of recording system **100**. Such audio may be received from an audio input device such as RCU audio input device **212** via audio input device port **214**. RCU audio input device **212** may be any type of commercially available audio input device such as a microphone and audio input device port **214** may be any commercially available audio input device port that is compatible with RCU audio input device **212** and the internal components of RCU **104**. The received audio as well as any digital signals (e.g., microphone input level, line input level, etc.) are then buffered and/or amplified by RCU preamp **216** and are converted from analog to digital by RCU analog to digital converter ("ADC") **222** such that the audio may be read in digital form by RCU local control unit **210**. This audio may then be processed and sent via RCU transmitter **208** in either analog or digital form. If the audio is to be sent in analog form, RCU local control unit **210** may be equipped with an on-board digital to analog converter ("DAC") or an independent DAC may be incorporated in RCU **104** without departing from the scope of the present invention. Or, alternatively, analog audio received from RCU audio input device **212** may be passed directly to RCU transmitter **208** for transmission in analog form to the other components of the recording system. In such embodiments, RCU transmitter **208** may be equipped with a frequency modulation ("FM") modulator or the like. Furthermore, in such embodiments, although the analog audio is passed through to RCU transmitter **208**, the audio signal may be additionally converted to digital form for local recording of the received audio. In yet another alternate embodiment, audio may be transmitted and recorded in analog form thereby eliminating RCU ADC **222**.

In the aforementioned embodiments in which the audio signal for a particular track of audio is converted to digital form for local recording of the received audio, identifiers such as a local audio device identifier that identifies the local audio device that recorded the respective audio, a track identifier that identifies the track of audio which may include the actor or actress recording the respective audio, etc. may be recorded with the recorded audio to allow the audio tracks to be easily and quickly identified post-recording and/or post-production. In some embodiments of the present invention, such identification information is stored in the local, nonvolatile memory of the local audio device as a text file, however, the present invention is not so limited. In another aspect of the present invention, such identification information is encoded in the audio file such that it may be decoded post-recording and/or post-production using methods known in the art. Additionally, such identification information may be integral to a timecode or completely distinct therefrom. Furthermore, such identification information may be programmed for each local audio device remotely via a remote control unit such as RCU **104**.

In some embodiments of the present invention, RCU local control unit **210** may be a digital signal processor such as Texas Instruments part number TMS320C5509A. However, the present invention is not so limited. Any combination of hardware and software may be substituted for any component described herein without departing from the scope of the present invention.

RCUs **104** may be handheld units such as RCU **104** depicted in FIG. **2B**. In such an embodiment, display **218** may be a small liquid crystal display ("LCD") or the like and keypad **220** may include a plurality of buttons that allow a user to perform local RCU functions including, but not limited to, those that relate to RCU transmitter frequency, group identification ("ID") code, unit ID code, and timecode generator mode. For example, the RCU transmitter frequency may be adjustable in predetermined frequency steps. In most cases, this frequency will be set to match the receiving frequency of other devices in the recording system (e.g., local audio devices). Or, when multiple local audio devices are incorporated into a group with an RCU, the RCU as well as other components of the recording system (e.g., local audio devices) may be assigned a group ID to ensure that the RCU is controlling the correct group of local audio devices. Similarly, the unit ID identifies the specific one of multiple local audio devices that a user wishes to control. Setting the unit ID ensures that the control signals transmitted by the RCU are received by the correct local audio device. Also, timecode generator mode allows the RCU to either generate its own timecodes or to receive timecodes from an external timecode generator.

In addition to allowing a user to modify local RCU settings, RCU keypad **220** and display **218** also allow the RCU to remotely control individual local audio devices. The user may perform a variety of functions for the local audio device including, but not limited to, transmitter and receiver frequencies, transmitter enable, microphone gain, high pass filter, record mode select, time code entry, playback control, audio bank storage, and status request.

For example, local audio device transmitter and receiver frequencies may be adjustable in predetermined frequency steps. Alternatively, the local audio device transmitter may be remotely enabled and disabled. Microphone gain may be adjusted, which in turn adjusts the current setting of a preamp such as local preamp **316**. Adjustment of the high pass filter may be incorporated to enable and disable, or

otherwise adjust, the high pass audio filter of the audio input device such as audio input device **312**.

In addition, record mode select allows recording modes such as endless loop record mode or timed record mode to be remotely adjusted. Timecodes may also be set remotely for each local audio device. Playback control allows one or more local audio devices to be commanded remotely to playback audio starting at a specific timecode. Completion of playback may be automatically or manually determined. Functions such as audio bank storage allow a remote user to manually store chunks of audio data in safe locations of the local audio device memory (i.e., in locations in which the audio data will not be overwritten). Finally, status of the local audio device may be requested. The status may be provided via display **218** or via spoken language generated by local audio device **102** and transmitted to a receiver or receiver/recorder combination for recording with the recorded audio.

The RCU may also allow a user to program data at each local audio device such as track identifiers, local audio device identifiers, and the like. In such scenarios, such identifiers are recorded with the respective audio to allow the track, local audio device, etc. of the recorded audio to be identified post-recording. That is, each segment of recorded audio may be associated with a specific take, track, or the like, as well as a specific local audio device. Such association allows each portion of recorded audio (e.g., a track of audio) to be quickly and easily identified post-production and/or post-recording without confusion.

Although many specific features and functions for the RCU have been delineated herein, other features and functions may be added or eliminated without departing from the scope of the present invention.

Additionally, handheld embodiments may include any one of a variety of commercially available batteries to function with the power supply **206** without departing from the scope of the present invention. Power supply **206** may be virtually any power component or combination thereof that is compatible with the other components of RCU **104** including, but not limited to, a Texas Instruments TPS62000DGS Power Module alone or in combination with a Linear Technology LTC3402 Synchronous Boost Converter.

However, non-handheld embodiments of RCU **104** are also envisioned such as tabletop models, personal computer ("PC") models, etc. Also, RCU **104** may be optionally equipped with external interface **252** (FIG. **2A**) to facilitate connection of RCU **104** to a PC, laptop PC, dumb terminal, or the like via external interface port **254**. Such an interface allows a user to control the components of recording system **100** via a graphical user interface or other software that may operate on a larger user interface. Such an interface may provide more features and functions than that available on a portable, handheld device such as programming and execution of complex playback scenarios, automatic initiation of complex playback scenarios based upon detected audio transmission errors, etc.

Turning next to FIG. **3A**, depicted is a block diagram of one embodiment of local audio device **102** in accordance with the present invention. In one aspect of the present invention, local audio devices **102** are digital, wireless audio transceivers. Such audio devices may be manufactured in the form of body-packs, such as those typically worn by news announcers, performers, and the like. In the depicted embodiment, local audio device **102** includes, inter alia, local receiver **302**, local timecode generator **304**, local power supply **306**, local transmitter **308**, local control unit

310, local audio input device 312, local audio input device port 314, local preamp 316, local display 318, local keypad 320, local ADC 322, local DAC 324, local amp 326, local audio output device port 328, local audio output device 330, memory 332, comparator 334, oscillator 336, and counter 338.

Local transmitter 308 also allows audio generated locally at local audio device 102 to be transmitted to the other components of recording system 100. Such audio may be received from an audio input device such as local audio input device 312 via local audio input device port 314. Local audio input device 312 may be any type of commercially available audio input device such as a microphone and local audio input device port 314 may be any commercially available audio input device port that is compatible with local audio input device 312 and the internal components of local audio device 102. The received audio as well as any digital signals (e.g., microphone input level, line input level, etc.) are then buffered and/or amplified by local preamp 316 and are converted from analog to digital by local ADC 322 such that the audio may be read in digital form by local control unit 310. This audio may then be processed and sent via local transmitter 308 in either analog or digital form. If the audio is to be sent in analog form, local control unit 310 may be equipped with an on-board DAC or an independent DAC may be incorporated in local audio device 102 without departing from the scope of the present invention. Or, alternatively, analog audio received from local audio input device 312 may be passed directly to local transmitter 308 for transmission in analog form to the other components of the recording system. In such embodiments, local transmitter 308 may be equipped with a frequency modulation (“FM”) modulator or the like. Furthermore, in such embodiments, although the analog audio is passed through to local transmitter 308, the audio signal may be additionally converted to digital form for local recording of the received audio. In yet another alternate embodiment, audio may be transmitted and recorded in analog form thereby eliminating local ADC 322.

The gain of audio received from audio input device 312 via audio input device port 314 may be adjusted via an exemplary gain adjustment circuit such as gain adjustment circuit 1326 as depicted in FIG. 15. When local control unit 310 wirelessly receives the desired gain setting as described in greater detail below with respect to FIG. 12, it converts the received setting to a digital command to be transmitted to gain adjustment circuit (“GAC”) DAC 1510. The digital command may be derived from a look up table or the like that equates incoming desired gain settings to corresponding GAC DAC 1510 commands. The GAC DAC 1510 receives its digital command and converts it to an analog signal that is applied to one or more GAC LEDs 1512. GAC LEDs 1512 may be any commercially available LEDs such as, but not limited to, a Lumex SML-LX0603SRW LED. The light generated by GAC LEDs 1512 varies based upon the digital command received from local control unit 310.

The light generated by GAC LEDs 1512, as well as the audio received locally from audio input device 312 is received by local preamp 316. In this embodiment of the present invention, local preamp 216 is a preamplification circuit. This circuit includes, inter alia, one or more photocells 1514 and a plurality of amplifiers 1516. Photocells 1514 may be any commercially available photocell such as, but not limited to, cadmium sulfide (“CdS”) photocells such as Silonex NSL-6112 photoconductive cells. Each photocell 1514 varies its resistance between two terminals based upon the amount of photons it receives. This varying resistance

varies the analog signals applied to the input terminals of the plurality of amplifiers 1516 to vary the amplification of the audio received from audio input device 312 as desired by a user of recording system 100. The amplified audio, as output by amplifiers 1516, is then transmitted to local ADC 322. Local ADC 322 converts the amplified audio signals to digital form for transmission to local control unit 310. It should be noted that the depicted gain adjustment and preamplification circuits are merely exemplary and any other compatible hardware or software capable of adjusting gain and/or amplifying analog signals may be substituted without departing from the scope of the present invention.

In some embodiments of the present invention, local control unit 310 may be a digital signal processor such as Texas Instruments part number TMS320C5509A. However, the present invention is not so limited. Any combination of hardware and software may be substituted for any component described herein without departing from the scope of the present invention.

Similarly, local receiver 302 allows audio received from other components of recording system 100 to be played locally at local audio device 102. Such audio may be received in either analog or digital form at local receiver 302. However, if the audio is to be received in analog form, local control unit 310 may be equipped with an on-board ADC or an independent ADC may be incorporated in local audio device 102 without departing from the scope of the present invention to allow local control unit 310 to receive the audio in digital form. Thereafter, the audio may be processed or relayed directly to local DAC 324, which converts the audio data back to analog form. The analog audio may then be amplified by local amp 326 prior to transmission through local audio output device port 328 to local audio output device 330. Local audio output device 330 may be any type of commercially available audio output device such as headphones, speakers, and the like, and local audio output device port 328 may be any commercially available audio output device port that is compatible with local audio output device 330 and the internal components of local audio device 102. Local receiver 302 may be virtually any receiver compatible with the other components of local audio device 102 including, but not limited to, a Micrel Semiconductor MICRF505 RadioWire® transceiver.

Memory 332 of local audio device 102 locally stores audio processed by local control unit 310 in one or more audio files. In one aspect of the present invention, local control unit 310 receives recordable audio from local audio input device 312, which may be worn by the performer and connects to local audio device 102 at local audio input device port 314. However, in alternate embodiments, local control unit 310 may also receive audio from other components of recording system 100 via local receiver 302. The locally stored audio files may include identification data such as local audio device identifiers, track identifiers, performer identifiers, and the like as discussed in greater detail above. Furthermore, the locally stored audio files include timestamps (e.g., timestamps may be stored in the header of the audio file) that indicate when, during the audio event, each segment of audio occurred. The timestamps may be generated based upon timecodes created by local timecode generator 304 or based upon master timecodes. Such master timecodes may be received using a plurality of methods or components including, but not limited to, wirelessly from a master timecode source through local receiver 302, from a timecode source connected to local audio input device port 314, and from local audio input device 312 wherein the master timecodes are received from an ultra-

sonic signal. Local timecode generator **304** may be synchronized with the master timecode generator during recording of the audio event as described in further detail below with respect to FIG. **5**. Or, alternatively, the timestamps may be synchronized post-recording as described in further detail below with respect to FIGS. **9** and **10**. Simultaneous with the local recording of audio received from local audio input device **312**, this audio may also be transmitted through local transmitter **308** to receiver **106** and/or recorder **108** to allow recording of the audio event. In this scenario, receiver **106** and/or recorder **108** may simultaneously record a multi-track recording of all of the single tracks of audio received from local audio devices **102**, which are worn by the performers of the audio event.

Memory **332** may be virtually any type of commercially available removable or non-removable memory including, but not limited to, flash memory cards, compact flash memory cards, Universal Serial Bus (“USB”) thumbdisks, and the like. Use of removable memories **332** facilitates removal and insertion of these memories into a PC or the like for electronic combination or mixing of the recorded audio data. Such electronic mixing may be performed via commercially available software such as Pro Tools or the like and may be performed in addition to or in lieu of live wireless recording of the audio event.

Local audio devices **102** also receive non-audio information (e.g., time reference signals, digital commands, audio, etc.) from other components of recording system **100** via local receiver **302**. During synchronous operation of recording system **100**, a portion of the received data may be used to synchronize local timecode generator **304** to the master timecode generator integral to one of the components of recording system **100** (e.g., RCU **104**, recorder **108**, etc.) using a process such as that described below with respect to FIGS. **4A**, **4B**, and **5** or an equivalent thereof. Alternatively, during asynchronous operation of recording system **100**, the received data may include master timecodes from the master timecode generator that may be used to timestamp individual audio samples and/or files such that the audio received at multiple local audio devices **102** may be synchronized post-recording using one of the methods discussed below with respect to FIGS. **9** and **10** or an equivalent thereof.

As described in further detail below with respect to FIG. **5**, local audio devices **102** operating in the synchronous mode may require one or more of comparator **334**, oscillator **336**, and counter **338**. In one aspect of the present invention, oscillator **336** is a 48 kilohertz (“kHz”) voltage controlled oscillator. However, alternate embodiments of oscillator **336** may be substituted without departing from the scope of the present invention including but not limited to a high speed clock divided to produce 48 kHz. In the embodiment of the present invention depicted in FIG. **3A**, oscillator **336** feeds the sample rate input of local ADC **322**, as well as counter **338**, which provides a time reference for local timecode generator **304**. In this configuration, if local ADC **322** is set to operate at 48 kHz, varying the voltage applied to the clock control input of oscillator **336** will proportionately vary the output of oscillator **336** and, consequently, the sample rate of local ADC **322** and the rate at which local timecode generator **304** keeps time.

When local audio devices **102** such as those depicted in FIG. **3A** are used in conjunction with recorders **108** that incorporate a single clock to both regulate the speed of the master timecode generator and control the internal recorder ADC sample rate, comparators **334** help maintain synchronization of local audio devices **102** with each other and with

recorder **108** by varying the speed of the respective local timecode generators **304** and the sampling rate of the respective local ADCs **322**. As per an algorithm or hard-wired logic that duplicates the sequence depicted in FIG. **5**, or an equivalent thereof, comparators **334** compare the timecodes generated by the master timecode generator with timecodes generated by the locally timecode generator and, if necessary, increase or decrease the speed of the respective local timecode generator **304** and the sampling rate of the respective local ADC **322** such that these speeds are synchronized with the speed of the master timecode generator and the ADC of recorder **108**. That is, comparators **334** generate, through software or hardware, the voltage that is applied to the clock control input of the respective oscillator **336** that proportionately varies the sample rate of local ADC **322** and the rate at which local timecode generator **304** keeps time as necessary to maintain synchronization with the sample rate of the ADC of recorder **108** and the master timecode generator, respectively. In this manner, all local audio devices **102** and recorder **108** sample at virtually identical sample rates allowing a wireless recorder **108**, or a wireless recorder/receiver combination, to accurately combine multiple independent tracks of audio, wherein each independent track of audio is received from one of the performer’s local audio device **102**.

Whenever playback of locally recorded audio is required (e.g., to remedy recording errors caused by transmission losses), RCU **104** transmits a digital command to all local audio devices **102** to playback the audio data stored in the respective memories **332** starting with and subsequent to a specific time reference as indicated by a specific timecode. The digital command is received by local receivers **302**, which transmit or relay the command to their respective local control unit **310**. Thereafter, local control units **310** access the data stored in the respective memory **332** and cause this data to be played or transmitted sequentially via local transmitter **308** starting with the data associated with the requested timecode. The use of timecodes and synchronization of local and master timecode generators, as well as local and recorder audio sampling rates, as discussed herein allows multiple local audio devices **102** to replay audio with the exact timing that occurred during the audio event.

Local audio devices **102** may be bodypacks such as the local audio device **102** depicted in FIG. **3B**. In such an embodiment, display **318** may be a small liquid crystal display (“LCD”) or the like and keypad **320** may include a plurality of buttons that allow a user to perform functions including, but not limited to, those that relate to transmitter frequency, receiver frequency, microphone gain, high pass filter, group ID code, unit ID code, transmitter encryption code, and transmitter operating mode. For example, transmitter and receiver frequencies may be adjustable in predetermined frequency steps. Microphone gain may be adjusted, which in turn adjusts the current setting of a preamp such as local preamp **316**. Adjustment of the high pass filter may be incorporated to enable and disable, or otherwise adjust, the high pass audio filter of the audio input device such as audio input device **312**.

When multiple local audio devices are incorporated in to a group, each local audio device in the group as well as other components of the recording system (e.g., an RCU) may be assigned a group ID. Similarly, the unit ID identifies each specific local audio device within the group of local audio devices.

For local audio devices transmitting encrypted audio and data, the transmitter encryption code is set to match the encryption code of all receiving devices (e.g., an RCU,

recorder, or receiver). Correctly setting this code allows the receiving device to properly decrypt the received transmission, while preventing unauthorized users from recording the data.

The operating mode of each local audio device can encompass any one of a number of modes. For example, the operating modes may include USA or European modes, as well as stereo modes. Selection of a specific mode may alter settings such as transmitter bandwidth, audio sampling parameters, and the like.

Although many specific features and functions for the local audio devices have been delineated herein, other features and functions may be added or eliminated without departing from the scope of the present invention.

Additionally, handheld embodiments may include any one of a variety of commercially available batteries to function with the power supply **306** without departing from the scope of the present invention. Power supply **306** may be virtually any power component or combination thereof that is compatible with the other components of local audio device **102** including, but not limited to, a Texas Instruments TPS62000DGS Power Module alone or in combination with a Linear Technology LTC3402 Synchronous Boost Converter.

Alternate embodiments of local audio device **102** are envisioned in which local receiver **302** are eliminated. In one such embodiment, local transmitter **308** is enabled whenever an audio event requiring recording is occurring. Local timecode generator **304** may be designed to generate timecodes whenever local transmitter **308** is enabled. When local transmitter **308** is not operating, the current value of local timecode generator **304** is stored in non-volatile memory to allow local timecode generator **304** to continue counting from the last generated timecode when the local transmitter **308** is re-enabled. Such embodiments include a timecode generator capable of generating unique timecodes for several years without a repeated timecode.

During recording, each local audio device **102** transmits data to one or more receivers and/or recorders. During recording, the receivers and/or recorders automatically detect corrupted audio data received from local audio devices **102** and maintain a list of same. The list of corrupted audio data contains references to the respective local audio device **102** from which the corrupted audio data was received to allow such data to be recovered post-recording.

Post-recording, memories **332** may be removed from each local audio device **102** such that locally recorded data may be retrieved and used to repair the corruption of the audio file generated by the receiver/recorders that occurred due to the receipt of corrupted audio data. Such data recovery may be performed using the multi-memory unit of the present invention or an equivalent. In one embodiment, the multi-memory unit may connect directly to the receivers and/or recorders to allow this equipment to directly retrieve the required audio data. In another embodiment, memories **332** may be connected directly to the receivers/recorders for retrieval of the audio data, thereby eliminating the need for any extraneous equipment such as a personal computer. Identifiers such as local audio device identifiers, track identifiers, performer identifiers, and the like may be decoded from the audio data to allow the file manipulator to more quickly and easily manipulate the audio data.

Since the timecodes generated locally by each local audio device **102** may vary with respect to each other, the receivers, and/or the recorders, the present invention provides a method for ensuring that audio data retrieved from memories **332** is inserted in the proper time sequence with respect

to the audio file(s) generated by the receiver/recorders. To achieve this, during recording, the receiver(s) and/or recorders generate or populate a cross-reference table, database, or the like that correlates the timecodes of the audio files generated by the receiver/recorders, as well as the timecodes of all audio data received from all local audio devices **102**. That is, the cross-reference mechanism correlates each timecode generated by a receiver or recorder to each timecode generated by each local audio device. In this manner, the timecodes of audio retrieved from memories **332** may be cross-referenced to determine the correlating timecode of the audio file generated by the receiver/recorders. Thereafter, the retrieved audio may optionally be re-stamped with the timecode of the receiver/recorder and inserted in its proper place within the receiver/recorder audio file. In this manner, audio may be wirelessly recorded with zero data loss.

Referring now to FIG. **4A**, illustrated is a flow diagram of one embodiment of a process for operation of a recording system such as recording system **100** in synchronous timecode generator mode in accordance with one embodiment of the present invention. Process **400** begins at **402**. For example, at **402**, one or more performers may each don a local audio device, such as local audio device **102** as described with respect to FIGS. **1**, **3A**, and **3B**. Also, a sound engineer or other personnel may be equipped with a control unit such as RCU **104**. Process **402** then proceeds to **404**.

At **404**, initialization occurs. During initialization, the local control unit such as local control unit **310** or other form of central processing unit is reset. Thereafter, the local transmitter, local receiver, ADC, DAC, and local timecode generator clock are initialized. The process then optionally proceeds to **406**, at which the sampling rate of the ADC is set. Alternatively, the sampling rate may be set via hardware or via software executed as part of a separate algorithm. In some embodiments of the present invention, a sample rate of 48 kHz is incorporated.

Next, at **408**, wireless receive channels are established between the local audio device and one or more wireless devices such as RCUs (e.g., RCU **104**), receivers, and audio recorders. To establish the channel, the local receiver of the audio device receives one or more data packets from the remote wireless device and stores the packets in a designated buffer. For example, when establishing wireless communication with a RCU, the local audio device may receive one or more data packets containing information such as a master timecodes, transport status (i.e., transport mode of an audio recorder), and the like. These packet(s) are then stored in an RX buffer (i.e., a reserved segment of memory used to hold data while it is being processed). Process **400** then proceeds to **410**.

At **410**, the local control unit reads the master timecode contained in the RX buffer and jam synchronizes the local timecode generator with the master timecode. The jam sync synchronizes the local audio device with the RCU while allowing the local audio device to supply its own timecode. Local supply of synchronized timecodes ensures proper timing during periods in which the master timecodes cannot be read (e.g., the RCU is temporarily unstable, wireless communication dropouts, etc.). Local supply of timecodes also allows local identifiers such as local track identifiers, local audio device identifiers, and the like to be added to the respective local audio device timecode. Such identifiers allow the locally recorded audio to be distinguished from audio recorded by other local audio devices. Such ability to distinguish is particularly useful to quickly and easily identify the audio tracks post-recording.

Next, at **412**, process **400** queries the transport status stored in the RX buffer. If at **412**, the transport status is stop, process **400** returns to **410**. However, if at **412**, the transport status is record, process **400** proceeds to **414**. At **414**, a new audio file is created in memory (e.g., on a flash card) and the newly created file is timestamped. In one aspect of the present invention, timestamping includes storing the timecode in the file header. Process **400** then proceeds to **416**.

At **416**, the local control unit waits for an audio sample interrupt from the ADC. Once an audio sample interrupt occurs, process **400** proceeds to **418**. At **418**, the audio sample is retrieved from the ADC and stored in the local memory. In one aspect of the present invention, the audio sample is stored in the next available address of the local memory. Next, at **420**, the timecode generator counter is incremented, thereby indicating that the time period for one sample of audio has elapsed.

Process **400** then proceeds to **422**, at which the local control unit transmits the audio sample through the local transmitter to the other wireless devices such as RCUs, receivers, audio recorders, and the like. For example, audio from multiple local audio devices may be transmitted to a multi-track recorder for recording of the audio event while each local audio device locally records its performer's audio. At **424**, process **400** queries the RF buffer of the local receiver to determine the availability of a new master timecode packet. If at **424**, a new master timecode packet has not been received from the RF receiver, process **400** returns to **416**. However, if at **424**, a new master timecode packet has been received, process **400** proceeds to **426** as depicted in FIG. 4B.

At **426**, process **400** executes a feedback loop algorithm, which modifies the speed of the local timecode generator as necessary to maintain its synchronization with the master timecode generator (e.g., a timecode generator contained within the RCU or master recorder). This algorithm may be implemented using any one of a variety of methods. In one embodiment of the present invention, a feedback loop algorithm, such as process **500** depicted in FIG. 5, modulates a low-pass filtered feedback error voltage that is supplied by the local control unit directly to the local oscillator. The local oscillator then controls the sample rate of the ADC and the speed of the local timecode generator by supplying the feedback error voltage to the ADC's sample rate input and the local timecode generator's clock control input. Alternatively, a comparator independent of the local control unit may perform the comparison of the master timecodes and the local timecodes and may vary the sample rate of the ADC and the speed of the local timecode generator by directly supplying the feedback error voltage to the oscillator. A variety of hardware and software equivalents of this function may be substituted without departing from the scope of the present invention.

Referring now to FIG. 5, the feedback loop algorithm begins at **502**. At **504**, the current local timecode is retrieved from the timecode generator such as local timecode generator **304** and is written to the variable TCgen. Process **500** proceeds to **506**. At **506**, the current master timecode is retrieved from the RX buffer of the local receiver and is written to the variable TCrx and process **500** proceeds to **508**. At **508**, variable TCdiff is calculated by subtracting TCrx from TCgen. Process **500** then proceeds to **510**, at which process **500** compares TCdiff to zero. If, at **510**, TCdiff is less than zero, process **500** proceeds to **512**, at which the feedback error voltage supplied to the local oscillator's DAC by the local control unit is increased above the previously supplied feedback error voltage. The local

oscillator's DAC then supplies the new feedback error voltage to the local oscillator, which, in turn, supplies a new clock input voltage to the local timecode generator and a new sample rate input to the ADC. In this manner, the speed of the local timecode generator and the sample rate of the ADC are increased to maintain synchronization with the master timecode generator. However, alternate embodiments of the present invention are envisioned in which only one of either the speed of the local timecode generator or the sample rate of the ADC is modified.

Alternatively, if at **510** TCdiff is not less than zero, process **500** proceeds to **514**, at which TCdiff is analyzed to determine if it is greater than zero. If yes, process **500** proceeds to **516** and the feedback error voltage supplied to the local oscillator's DAC by the local control unit is decreased below the previously supplied feedback error voltage. The local oscillator's DAC then supplies the new feedback error voltage to the local oscillator, which, in turn, supplies a new clock input voltage to the local timecode generator and a new sample rate input to the ADC. In this manner, the speed of the local timecode generator and the sample rate of the ADC are decreased to maintain synchronization with the master timecode generator. However, alternate embodiments of the present invention are envisioned in which only one of either the speed of the local timecode generator or the sample rate of the ADC is modified. Furthermore, alternate embodiments are envisioned in which an inverse relationship occurs (e.g., DAC voltage is increased when TCdiff is greater than zero and it is decreased when TCdiff is less than zero).

If TCdiff is neither less than zero as determined at **510** or greater than zero as determined at **514**, then TCdiff is equal to zero. In this scenario, the local and master timecode generators are synchronized and, therefore, no adjustment is made to the speed of the local timecode generator. At this point, process **500** ends at **518**.

Although FIG. 5 depicts one method of performing a feedback loop, many variations of this feedback loop may be substituted without departing from the scope of the present invention. For example, the feedback loop may be implemented as a digital phased locked loop that re-samples the audio in a manner that simulates a hardwired feedback loop. Also, the feedback loop may include a low pass filter.

Referring back to FIG. 4B, after execution of the feedback loop algorithm at **426**, process **400** proceeds to **428**. At **428**, the local timecode generator is jam synchronized with the newly received master timecode read from the RX buffer. Next, process **400** optionally proceeds to **430**, at which a timecode is stored as an escape sequence in the next available address of the local memory. The escape sequence stores a master timecode in addition to the locally generated timestamp. This escape sequence may be used post-processing to resample the audio based upon interpolated master timecode data. Process **400** then proceeds to **432**. At **432**, process **400** queries the continuous loop record mode. If at **432** the continuous loop record mode is enabled, process **400** returns to **416** to wait for an audio sample interrupt from the ADC as discussed above. However, if at **432**, the continuous loop record mode has not been enabled, process **400** proceeds to **434**. At **434**, process **400** queries the transport status. If at **434** the transport status is record, process **400** returns to **416** to wait for an audio sample interrupt from the ADC as discussed above. However, if at **434**, the transport status is stop, process **400** returns to **410**, at which process **400** continuously jam synchronizes the local timecode generator with the master timecodes received in the RX buffer until the transport status changes from stop to record at **412**.

Turning next to FIG. 6, illustrated is a flow diagram of one embodiment of a process for recording audio and for replaying and re-recording segments of missed audio in accordance with embodiments of the present invention. Process 600 begins at 602. For example, at 602, one or more performers may each don a local audio device, such as local audio device 102 as described with respect to FIG. 2A. Process 600 then proceeds to 604.

At 604, a master unit, such as RCU 104, receiver 106, or recorder 108 transmits master timecodes to each local audio device, and process 600 proceeds to 606. At 606, each local audio device synchronizes (e.g., jam syncs) its respective on board local timecode generator with the master timecodes received from the master unit, thereby synchronizing all local audio device timecode generators with the master timecode generator contained within the master unit. Process 600 then proceeds to 608. At 608, local audio devices begin locally recording audio received from an audio input device. This audio is stored in the memory of the respective local audio device with timestamps generated by the local timecode generator. Identifiers such as track identifiers, local audio device identifiers, and the like may also be stored in the memory of the respective local audio device to allow the locally recorded audio to be associated by track, local audio device, or the like post-recording. Each local audio device also simultaneously transmits its received audio to recorders or receiver/recorder combinations such as receivers 106 and recorders 108 in real time. Such audio may be transmitted alone or in combination with its respective timecodes. The audio received from each of the local audio devices (e.g., the local audio device of each performer) may be combined to create one or more multi-track audio files that are stored with master timestamps generated by the receiver/recorder's internal master timecode generator. In some embodiments of the present invention, local timecodes generated by the respective local audio device are stored with the multi-track audio files in addition to the master timestamps.

Process 600 then proceeds to 610. At 610, process 600 queries the initiation of audio replay. The initiation of audio replay may be manual or automatic. For example, if a user detects a loss of audio, the user may manually initiate audio replay beginning at the specific timecode reference at which the transmission error occurred. Alternatively, if a loss of audio is automatically detected by the receiving equipment, a playback request may be sent from the receiving equipment to the controlling unit such as a remote control unit. In response, such controlling unit may command the local audio devices to replay or retransmit the missed audio to the receiving equipment beginning at the timecode at which the loss of data occurred or at a conveniently close time thereto (e.g., zero to ten seconds prior to the loss of data).

If, at 610, audio replay is not initiated either manually or automatically, process 600 returns to 608. However, if, at 610, audio replay is initiated, process 600 proceeds to 612. At 612, a controlling unit, such as RCU 104, sends a signal to the local audio devices requesting playback of the stored audio starting at a specific timecode.

Next, at 614, each local audio device processes the playback command and synchronizes playback to the timecode contained in the playback command. In addition, at least one local audio device transmits the synchronization data to the receiving equipment (e.g., receiver 106, recorder 108, etc.) to synchronize recording of the replayed audio. Process 600 then proceeds to 616. However, in alternate

embodiments of the present invention, the receiving equipment and the local audio devices may simultaneously receive the synchronization and time reference data from the transmitting equipment (e.g., the controlling unit).

At 616, one or more local audio devices transmit, or replay, its respective stored audio starting with the audio that corresponds to the time specified by the timecode. The receiving equipment simultaneously records the replayed audio from each of the local audio devices and stores it within the previously recorded audio according to its timecode data. That is, due to the highly accurate synchronization of all of the components of the recording system, the receiving equipment may insert the replayed audio data that was not recorded during the audio event due to wireless transmission errors into the original recording at the nearly the exact time at which the missed audio originally occurred, thereby compensating for any transmission losses. Process 600 then proceeds to 618. At 618, one or more local audio devices continue to replay audio while the receiving equipment records the audio.

At 620, process 600 queries the status of audio replay. If, at 620, the audio has been fully replayed, process 600 proceeds to 608. At 608, the local audio devices may record a new audio event or may replay a different segment of recorded data. Otherwise, if, at 620, all requested audio has not been replayed or re-recorded, process 600 returns to 618.

Referring now to FIG. 7, illustrated is a flow diagram of one embodiment of a process for operation of a recording system such as recording system 100 in asynchronous timecode generator mode in accordance with one embodiment of the present invention. Process 700 begins at 702. For example, at 702, one or more performers may each don a local audio device, such as local audio device 102 as described with respect to FIGS. 1, 3A, and 3B. Also, a sound engineer or other personnel may be equipped with a control unit such as RCU 104. Process 702 then proceeds to 704.

At 704, initialization occurs. During initialization, the local control unit such as local control unit 310 or other form of central processing unit is reset. Thereafter, the local transmitter, local receiver, ADC, DAC, and clock are initialized. The process then proceeds to 706, at which the sampling rate of the ADC is set. In some embodiments of the present invention, a sample rate of 48 kHz is incorporated.

Next, at 708, wireless receive channels are established between the local audio device and one or more wireless devices such as RCUs (e.g., RCU 104), receivers, and audio recorders. To establish the channel, the local receiver of the audio device receives one or more data packets from the remote wireless device and stores the packets in a designated buffer. For example, when establishing wireless communication with a RCU, the local audio device may receive one or more data packets containing information such as a timecode, transport status (i.e., transport mode of an audio recorder), and the like. These packet(s) are then stored in an RX buffer. Process 700 then proceeds to 710.

At 710, the local control unit reads the transport status and the master timecode contained in the RX buffer. Next, at 712, process 700 queries the transport status. If at 712, the transport status is stop, process 700 returns to 710. However, if at 712, the transport status is record, process 700 proceeds to 714. At 714, a new audio file is created in memory (e.g., on a flash card) and the timecode is stored in the header of the newly created file. Such timecode may optionally include identification information such as track identifiers, local audio device, identifiers, and the like. Or, alternatively, such identification information may be stored in the newly created file in a location other than the timecode. For example, such identification information may be stored in

the data stream in the header of the newly created file. However, the present invention is not so limited. Process 700 then proceeds to 716.

At 716, the local control unit waits for an audio sample interrupt from the ADC. Once an audio sample interrupt occurs, process 700 proceeds to 718. At 718, the audio sample is retrieved from the ADC and stored in the local memory. In one aspect of the present invention, the audio sample is stored in the next available address of the local memory. Process 700 then proceeds to 720, at which the local control unit transmits the audio sample through the local transmitter to the other wireless devices such as receivers, audio recorders, and the like.

At 722, process 700 queries the RF buffer of the local receiver to determine the availability of a new master timecode packet. If at 722, a new master timecode packet has not been received from the RF receiver, process 700 returns to 716. However, if at 722, a new master timecode packet has been received, process 700 optionally proceeds to 724. At 724, the timecode is stored as an escape sequence in the next available address of the local memory. Process 700 then proceeds to 726. At 726, process 700 queries the continuous loop record mode. If at 726 the continuous loop record mode is enabled, process 700 returns to 716 to wait for an audio sample interrupt from the ADC as discussed above. However, if at 726, the continuous loop record mode has not been enabled, process 700 proceeds to 728. At 728, process 700 queries the transport status. If at 728 the transport status is record, process 700 returns to 716 to wait for an audio sample interrupt from the ADC as discussed above. However, if at 728, the transport status is stop, process 700 returns to 710, at which process 700 continuously reads the transport status and master timecodes from the RX buffer until the transport status changes from stop to record at 712.

Operation of the present invention in asynchronous mode allows one or more components of local audio devices such as local audio devices 102 (e.g., local timecode generator, comparator, counter, etc.) to be eliminated in embodiments in which the local audio devices utilize master timecodes generated by the master timecode generator rather than locally generated timecodes.

Referring next to FIG. 8, depicted is multi-memory unit 800 for reading and/or reformatting audio files recorded on a plurality of local audio device memories (e.g., memories 332). In its simplest form, such as the embodiment depicted in FIG. 8, multi-memory unit 800 includes a plurality of individual memory ports 802a-802f (e.g., flash memory card drives, compact flash memory card drives, USB thumbdisk ports, etc.). Also optionally included is a plurality of memory status displays 804a-804f to indicate to a user which memory ports 802 are in use. Similarly, power status display 806 and external connection status display 808 may be optionally included to indicate the presence of power and an external connection (e.g., a personal computer), respectively. Multi-memory unit 800 may be equipped with an integral user interface or may be connected to an external interface (e.g., a personal computer) to allow the audio files contained on each memory to be manipulated and/or read.

In one aspect of the present invention, the memory of each local audio device such as local audio device 102 may be removed after completion of a performance, videotaping, etc. Each memory may then be inserted into a corresponding one of memory ports 802. Thereafter, all of the individual audio files may be combined to provide one or more comprehensive audio files. Or, alternatively, each audio file

may be individually reformatted or otherwise manipulated prior to creation of one or more comprehensive audio files.

In embodiments of the present invention in which the recording system recorded the audio event in asynchronous mode, or in which long periods (e.g., 8 hours) of recording occurred, multi-memory unit 800 may be used to resample the audio samples to ensure that each audio file's timestamps are properly synchronized. One example of such as process is illustrated in the flowchart of FIG. 9.

In some embodiments of the present invention, multi-memory unit 800 may allow identification information such as track identifiers, local audio device identifiers, and the like to be added to each portion of audio stored in memory 332. In such embodiments, multi-memory unit 800 may have the ability to modify the timecode(s) associated with each portion of audio recorded on each memory 332 to add, modify, or delete the desired identification information. Or, alternatively, multi-memory unit 800 may have the ability to add such identification information to each portion of audio stored in memory 332 in a location other than the timecode (e.g., in a file header).

Referring now to FIG. 9, illustrated is a flow diagram of one embodiment of a process for interpolating timestamps for unstamped audio samples (i.e., audio samples that are not associated with a master timecode timestamp) based upon the timestamps of stamped audio samples (i.e., audio samples that are associated with a master timecode timestamp), and resampling the audio samples to include the interpolated timestamps in accordance with embodiments of the present invention. After recording of an audio event, the audio data stored in the memory of the local audio device (e.g., memory 332) will typically be stored as an audio sample stream wherein approximately one out of every one thousand to one hundred thousand samples includes a timestamp generated by a remote master timecode generator. However, the interval between timestamped audio samples may be greater than the aforementioned interval if the wireless timecode link was less reliable than a standard wireless link.

The resampling process depicted in FIG. 9, and equivalents thereof, analyze the occurrence of the relatively sparse timestamped audio samples to generate a linear interpolation or a best fit curve. This curve is then used to interpolate timestamps for the unstamped audio samples. After the timestamp of each audio sample has been interpolated, the audio samples may then be re-sampled such that the audio samples are now synchronized with samples generated by the master timecode generator. In one aspect of the present invention, the audio samples are resampled based upon the calculated curve to simulate the condition of an ADC whose sample rate input was driven directly by the master timecode generator's source.

If all of the audio from all local audio devices is resampled in this manner, each resulting resampled audio file appears as if it was originally sampled with an accurate audio sample clock derived from the master timecode source. This resampling allows each audio file to include a single timestamp that marks the master timecode of the first audio sample of the audio file. Furthermore, since the audio files now appear as if they have been sampled by an extremely accurate audio sample clock, each audio sample's timestamp may be accurately calculated based solely on the audio sample rate and the timestamp of the first audio sample of the audio file. This condition allows the audio files to be formatted and/or stored as a standard timecoded broadcast .WAV file, thereby allowing them to be read, edited, etc. using standard, commercially-available editing

systems. That is, the files may be processed in the same manner as if the audio file had been generated by a standard multi-track audio recorder. Such condition allows the present invention to be easily integrated with other industry standard recording equipment.

One such resampling process is illustrated in FIG. 9. Process 900 begins at 902. For example, at 902, one or more local audio device memories may be removed from its respective local audio device and may be inserted into a multi-memory unit 800, or an equivalent thereof. Process 902 then proceeds to 904.

At 904, process 900 determines the desired starting and ending timecodes and stores this data in the variables TimeCodeStart and TimeCodeEnd, respectively. The desired starting and ending timecodes may be input by a user or may be suggested or automatically determined by the algorithm. Process 900 then proceeds to 906. At 906, a variable, *i*, is initialized to a value of zero. The variable *i* corresponds to the position of audio samples or data points in a data array represented by the variable AudioSample[*i*]. Process 900 then proceeds to 908.

At 908, process 900 begins an iterative search for the audio file that matches the desired starting timecode of the output file by comparing the value of TimeCodeStart with the value of the timecode of AudioSample[*i*]. If, at 908, the value of TimeCodeStart is equal to the value of the AudioSample[*i*] timecode, process 900 proceeds to 912. However, if at 908 the value of TimeCodeStart is not equal to the value of the AudioSample[*i*] timecode, process 900 proceeds to 910. At 910, the variable *i* is increased by a value of one thereby allowing the value located in the next position of the audio sample array to be compared to the value of TimeCodeStart when process 900 returns to 908.

If the value of TimeCodeStart is equal to the value of the AudioSample[*i*] timecode, process 900 proceeds to 912. At 912, a variable, *n*, is initialized to a value of one. The variable *n* is added to the variable *i* to allow process 900 to continue to traverse the audio sample array while maintaining the location of the audio sample at the starting timecode, which is represented by the variable AudioSample[*i*]. Process 900 then proceeds to 914. At 914, the value of the AudioSample[*i+n*] timecode is compared to the value of TimeCodeEnd. If at 914, the value of the AudioSample[*i+n*] timecode is greater than or equal to the value of TimeCodeEnd, process 900 proceeds to 916. At 916, the value of the AudioSample[*i+n*] timecode is again compared to the value of TimeCodeEnd. If at 914, the value of the AudioSample[*i+n*] timecode is greater than the value of TimeCodeEnd, process 900 proceeds to 928, at which process 900 terminates. However, if at 916, the value of the AudioSample[*i+n*] timecode is equal to the value of TimeCodeEnd, process 900 proceeds to 922.

Conversely, if at 914, the value of the AudioSample[*i+n*] timecode is less than the value of TimeCodeEnd, process 900 proceeds to 918. At 918, the value of the AudioSample[*i+n*] timecode is compared to the value of TimeCodeEscapeSequence. If, at 918, the value of the AudioSample[*i+n*] timecode is not equal to the value of TimeCodeEscapeSequence, process 900 proceeds to 920 where the variable *n* is increased by one and process 900 returns to 914. However, if at 918, the value of the AudioSample[*i+n*] timecode is equal to the value of TimeCodeEscapeSequence, process 900 proceeds to 922.

At 922, the average time period “*T*” that elapsed between the audio samples that occurred between AudioSample[*i*] and AudioSample[*i+n*] may be calculated by subtracting the value of the timecode of AudioSample[*i*] from the value of

the timecode of AudioSample[*i+n*] and dividing by *n*, wherein *n* is now equivalent to the number of audio samples that occurred between the current timestamped audio sample and the previous timestamped audio sample. Process 900 then proceeds to 924. At 924, AudioSamples[*i*] through AudioSamples[*i+n*] are re-sampled at any desired sample rate based upon the value of *T* as calculated in 922, or any other desired sample rate, using an audio resampling algorithm (e.g., linear interpolation). Process 900 then proceeds to 926, at which the variable *i* is set to a value equal to the current value of *i* plus the current value of *n* and process 900 returns to 912. The iterative process continues until the value of the AudioSample[*i+n*] timecode is greater than the value of TimeCodeEnd, whereby process 900 proceeds to 928, at which process 900 terminates.

A similar interpolation algorithm, such as the algorithm depicted in FIG. 10, may be incorporated to break down single large audio files (e.g., an audio file recording the filming of multiple movie takes over a continuous eight hour period as a single eight-hour audio file) into smaller, more useful files (e.g., one audio file per take). These smaller files will allow the audio recorded locally by the local audio devices to be more easily matched or synchronized with the individual audio files recorded by a master recorder such as recorder 108.

In one use of an embodiment of the present invention, multiple local audio devices store audio samples with wirelessly-received timecode and transport status samples continuously for the entire duration of the work day (e.g., an 8 hour period). In a typical scenario, while the local audio devices are recording continuously, a technician intermittently records segments of the eight-hour audio event. For example, in a film setting, each segment would typically represent a movie ‘take’ and might range from one to five minutes in duration. Consequently, the master recorder generates individual audio files (i.e., at least one audio file for each recorded segment such as a movie take), whereas each local audio device generates one massive audio file. Therefore, there is a need for a method of segmenting each large local audio file into smaller audio files that correspond to the segments recorded by the master recorder.

The segmentation method (i.e., the method of segmenting the large local audio devices’ files to match the multiple, smaller master recorder’s audio file) requires knowledge of which portions of the single local audio device audio file are important and which portions can be discarded. This information can be inferred from the transport status of the master recorder since it is typically operated by someone with this knowledge. Therefore, when the transport status of the master recorder changes from stop to record, it can be inferred that a new master recorder audio file begins, and, subsequently, when the transport status of the master recorder changes from record to stop, it can be inferred that the same master recorder audio file has ended. In addition, when the transport status of the master recorder remains in the stop mode, it can be inferred that the audio recorded by the local audio device during this time period may be discarded. This audio may be discarded post-processing as per algorithms such as that depicted in FIG. 10 or during live recording.

In embodiments of the present invention in which such data is discarded during live recording, the transport status and master timecode of the master recorder are wirelessly transmitted to the local audio devices. This information may be processed by the local audio devices to allow them to create a new audio file with the current master timecode of the master recorder whenever the received transport status

and master timecode indicate that the transport status has changed from stop to record. Similarly, the local audio devices may end the newly created audio file when the received transport status indicates that it has changed from record to stop. In this scenario, the resulting local audio device files will automatically be segmented and will each be marked with a master timestamp at the beginning of each file.

However, in embodiments of the present invention in which unimportant audio is not discarded during live recording and, therefore, one or more large audio files are created, the large audio files may be segmented as per a process such as process 1000 as illustrated in FIG. 10. Process 1000 begins at 1002 at which one or more local audio devices have continuously recorded a lengthy quantity of audio data. Process 1000 then proceeds to 1004.

At 1004, a copy of the audio file directory containing the segmented audio files that correspond to the same time period as the local audio device's single large audio file is obtained from the master recorder. Process 1000 then proceeds to 1006. At 1006, a variable *y* is initialized to a value of zero. The variable *y* corresponds to the number of each file contained in the audio file directory copied from the master recorder. Process 1000 then proceeds to 1008, at which the variable *y* is increased by one and a variable *x* is initialized to a value of one. The variable *x* corresponds to the position of each audio sample within a particular file. Process 1000 then proceeds to 1010, at which the copied audio file directory is queried to determine if a file[*y*] (i.e., the file named with the number that corresponds to the value of *y*) exists in the audio file directory. If no, process 1000 proceeds to 1028 and terminates.

If file[*y*] does exist, process 1000 proceeds to 1012, at which process 1000 determines the starting and ending timecodes for file[*y*] and stores them in the variables TimeCodeStart and TimeCodeEnd, respectively. Process 1000 then proceeds to 1014, at which process 1000 compares the value of TimeCodeStart to the value of the timecode associated with AudioSample[*x*] stored in the memory of the local audio device. If at 1014 the value of TimeCodeStart is not equal to the value of the timecode associated with AudioSample[*x*], process 1000 proceeds to 1016. At 1016, the variable *x* is increased by one and process 1000 returns to 1014. In this manner, TimeCodeStart is compared to each consecutive AudioSample[*x*] until the AudioSample timestamped with a value equal to TimeCodeStart is found. In some embodiments of the present invention, process 1000, or an equivalent thereof, is performed after process 900, or an equivalent thereof, to ensure that each of the audio samples has a timestamp (e.g., an interpolated timestamp).

When the AudioSample[*x*] having a timecode equivalent to TimeCodeStart is found at 1014, process 1000 proceeds to 1018. At 1018, AudioSample[*x*] is extracted and process 1000 proceeds to 1020, at which the variable *x* is increased by one and process 1000 proceeds to 1022. At 1022, process 1000 compares the value of TimeCodeEnd to the value of the timecode associated with AudioSample[*x*]. If at 1022, the value of TimeCodeEnd is not equal to the value of the AudioSample[*x*] timecode, process 1000 returns to 1018, whereupon audio samples are consecutively extracted until the timecode of the current AudioSample[*x*] equals TimeCodeEnd. If, at 1022, the value of TimeCodeEnd is equal to the value of the timecode of AudioSample[*x*], process 1000 proceeds to 1024, at which the final AudioSample[*x*] of the segmented audio file is extracted and the audio file is saved at 1026.

Process 1000 then proceeds to 1008, at which the variable *y* is increased by one and process 1000 proceeds to 1010 at which the audio file directory is queried to determine the existence of file[*y*]. If file[*y*] exists, process 1000 proceeds to 1012 and it continues thereafter as described above. However, if at 1010, it is determined that file[*y*] does not exist, process 1000 proceeds to 1028, at which it terminates.

Turning now to FIGS. 13A and 13B, depicted are a block diagram and a front view, respectively, of one embodiment of recorder 108 in accordance with the present invention. As best seen in FIG. 13A, the depicted embodiment of recorder 108 includes, inter alia, recorder power supply 1306, recorder memory 1308, recorder local control unit 1310, adjuster 1312, adjuster ADC 1314, recorder audio input device 1316, recorder audio input device port 1318, timecode port 1320, recorder preamp ADC 1322, recorder preamp 1324, and recorder DAC 1326.

Recorder power supply 1306 may be an AC electric plug compatible with an electrical receptacle as is commonly known in the art. Additionally, portable embodiments may include any one of a variety of commercially available batteries to function with power supply 1306 without departing from the scope of the present invention. Recorder power supply 1306 may be virtually any power component or combination thereof that is compatible with the other components of recorder 108 including, but not limited to, an SL Power Electronics PW174KB1203F01 AC adapter.

In some embodiments of the present invention, recorder local control unit 1310 is electrically coupled to the other components of recorder 108, and it is a digital signal processor programmed with software such as that depicted in FIG. 11 to, for example, remotely control various functions of local audio devices 102. For example, recorder local control unit 1310 may be programmed with an algorithm capable of remotely controlling the amplification of audio received at local audio devices 102. In the depicted embodiment of the present invention, recorder local control unit 1310 is a digital signal processor such as a Texas Instruments TMS320C6713GDP digital signal processor, however, the present invention is not so limited. Any combination of hardware and software capable of executing a process such as that depicted in FIG. 11 may be substituted for any component described herein without departing from the scope of the present invention.

Recorder memory 1308 is electrically connected to recorder local control unit 1310 and stores information therein as discussed in further detail below with respect to FIG. 11. In the depicted embodiment of the present invention, recorder memory 1308 is a Western Digital WD1600BEVE hard drive. However, recorder memory 1308 may be virtually any type of commercially available removable or non-removable memory including, but not limited to, flash memory cards, compact flash memory cards, Universal Serial Bus ("USB") thumbdisks, and the like.

Referring now to FIGS. 13A and 13B, depicted is one embodiment of a front control surface of recorder 108 in accordance with the present invention. Recorder 108 includes a plurality of adjusters 1312*a* through 1312*d*. In the depicted embodiment, adjusters 1312 are potentiometers. That is, each adjuster 1312 includes a knob protruding from the control surface of recorder 108 that, when turned, slides a wiper terminal across a resistive material to alter the electrical resistance of adjuster 1312. A user may alter the position of adjuster 1312, for example, to adjust the gain of a microphone connected to a local audio device 102 as discussed in greater detail below with respect to FIGS. 11

and **12**. Adjusters **1312** may be any commercially available potentiometer such as, but not limited to, an Alps Electric Co., Ltd. RK09L11401A5L potentiometer.

In the depicted embodiment of the present invention, each adjuster **1312** may be set to local or remote trim mode by pressing its associated pushbutton **1313a-1313d**. Similarly, recording may be initiated by pressing pushbutton **1313e** or stopped by pressing pushbutton **1313g**. Or, playback may be initiated by pressing pushbutton **1313f**. In the depicted embodiment of the present invention, pushbutton **1313** may be a flat illuminated pushbutton, however, the present invention is not so limited. Any combination of hardware and software capable of indexing adjuster **1312** to a local or remote trim mode, or initiating or stopping recording, or initiating playback, as described in greater detail below, may be substituted without departing from the scope of the present invention.

In remote trim mode, each adjuster **1312** modifies the gain of audio received via an audio input device (e.g., audio input device **312** of FIG. **3A**) connected to audio input device port **314** (FIG. **3A**) as also described in greater detail below with respect to FIG. **11**. In local trim mode, each adjuster **1312** modifies the gain of audio received via an audio input device (e.g., audio input device **1316**) connected to audio input device port **1318** as also described in greater detail below with respect to FIG. **11**. Recorder audio input device **1316** may be any type of commercially available audio input device such as a microphone and recorder audio input device port **1318** may be any commercially available audio input device port that is compatible with recorder audio input device **1316** and the internal components of recorder **108**. The received audio, as well as any digital signals (e.g., microphone input level, line input level, etc.), are then buffered and/or amplified by recorder preamp **1324** and are converted from analog to digital form by recorder preamp ADC **1322** such that the audio may be read in digital form by recorder control unit **1310**.

Each adjuster **1312** is electrically coupled to a respective, dedicated adjuster analog-to-digital converter (“ADC”) **1314** (See FIG. **13A**). In turn, each adjuster ADC **1314** is electrically coupled to a dedicated analog input of recorder local control unit **1310**. As a user rotates the knob associated with a particular adjuster **1312**, the voltage across adjuster **1312** varies. Once adjuster **1312** is set to the desired position, the respective adjuster ADC **1314** measures the voltage across adjuster **1312** and converts it to a numeric value to be read by recorder local control unit **1310**. This numeric value corresponds to the desired gain, or amplification, of the audio received either at recorder **108** (i.e., if adjuster **1312** is set to local trim mode) or at the respective local audio device **102** (i.e., if adjuster **1312** is set to remote trim mode) as discussed in further detail below with respect to FIG. **11**. Adjuster ADC **1314** may be any commercially available analog-to-digital converter such as, but not limited to, a Maxim Integrated Products MAX1202BCAP analog-to-digital converter.

The gain of audio received from audio input device **1316** via audio input device port **1318** may be adjusted via an exemplary gain adjustment circuit such as gain adjustment circuit **1326** as depicted in FIG. **15**. When local control unit **1310** receives the desired gain setting from adjuster ADC **1314** as described above, it converts the received setting to a digital command to be transmitted to gain adjustment circuit (“GAC”) DAC **1510**. The digital command may be derived from a look up table or the like that equates incoming desired gain settings to corresponding GAC DAC **1510** commands. The GAC DAC **1510** receives its digital

command and converts it to an analog signal that is applied to one or more GAC LEDs **1512**. GAC LEDs **1512** may be any commercially available LEDs such as, but not limited to, a Lumex SML-LX0603SRW LED. The light generated by GAC LEDs **1512** varies based upon the digital command received from recorder local control unit **1310**.

The light generated by GAC LEDs **1512**, as well as the audio received locally from audio input device **1316** is received by recorder preamp **1324**. In this embodiment of the present invention, recorder preamp **1324** is a preamplification circuit. This circuit includes, inter alia, one or more photocells **1514** and a plurality of amplifiers **1516**. Photocells **1514** may be any commercially available photocell such as, but not limited to, cadmium sulfide (“CdS”) photocells such as Silonex NSL-6112 photoconductive cells. Each photocell **1514** varies its resistance between two terminals based upon the amount of photons it receives. This varying resistance varies the analog signals applied to the input terminals of the plurality of amplifiers **1516** to vary the amplification of the audio received from audio input device **312** as desired by a user of recording system **100**. The amplified audio, as output by amplifiers **1516**, is then transmitted to recorder preamp ADC **1322**. Recorder preamp ADC **1322** converts the amplified audio signals to digital form for transmission to recorder control unit **1310**. It should be noted that the depicted gain adjustment and preamplification circuits are merely exemplary and any other compatible hardware or software capable of adjusting gain and/or amplifying analog signals may be substituted without departing from the scope of the present invention.

In the depicted embodiment, four (4) adjusters **1312** are provided to facilitate adjustment of local or remote audio gain, or amplification. However, a greater or lesser quantity of adjusters **1312** may be provided without departing from the scope of the present invention. Additionally, in an alternate embodiment of the present invention, a single adjuster **1312** may be employed to adjust the local or remote gain, or amplification. In such an embodiment, the recorder audio input port **1318** or the audio input port **314** of the local audio device **102** to be adjusted is selected (via software or hardware) prior to use of adjuster **1312** to set the respective gain or amplification.

Timecode port **1320** is electrically connected to recorder local control unit **1310** and is provided to transmit timecode information from recorder **108** to another component of recording system **100** (e.g., RCU **104**) as needed. For example, if recorder **108** is acting as a master timecode generator, RCU **104** may be hardwired to recorder **108** to receive timecodes from recorder **108** for synchronization purposes. Additionally, timecode port **1320** may transmit data packets to RCU **104** containing commands to remotely control the functions of local audio devices **102** such as, but not limited to, the gain, or amplification, of audio recorded at local audio device **102** as discussed in greater detail below with regards to FIG. **11**.

Turning now to FIG. **11**, depicted is a process **1100** for remotely generating commands for one or more local audio devices **102**. In our exemplary embodiment, these commands are generated by a user at recorder **108**, however, alternate embodiments of the present invention are envisioned in which such commands are generated by another component of recording system **100** such as, but not limited to, mixer **109** as discussed in greater detail below. In the exemplary embodiment, process **1100** is executed by recorder local control unit **1310** and begins at **1102**. Process **1100** then proceeds to step **1104**, at which the value of the variable **N** is set to equal a value of zero. Each adjuster **1312**

is associated with a unique value of variable N that corresponds to its position relative to other adjusters **1312**. For example, since adjuster **1312a** is the first adjuster in a row of adjusters **1312** (as read from left to right and as depicted in FIG. **13B**), it is assigned a variable N value of one (1). Each subsequent adjuster **1312** is associated with the next higher value of variable N. That is, adjuster **1312b** is assigned a variable N value of two (2), adjuster **1312c** is assigned a variable N value of three (3), etc.

Next, at step **1106**, the value of variable N is incremented by one (1). Therefore, on the first iteration of process **1100**, the process is performed for the adjuster **1312** having a variable N value of one (1) (i.e., adjuster **1312a**). Each time the process returns to step **1106**, the value of N is incremented by one (1) to perform the same process on the next adjuster. At the point that process **1100** has been performed for all adjusters **1312** (i.e., at step **108** when the value of N exceeds the value of the variable N of the adjuster having the highest variable N value), process **1100** returns to **1104** at which it resets the value of variable N to zero to restart the process beginning with the adjuster having the lowest variable N value. In this manner, the position of all adjusters **1312** are continually read and processed, as required, in a sequential manner and as discussed in greater detail below. This ensures that recording system **100** is constantly provided with updated information as described in greater detail below.

Next, at step **1108**, the current value of N is compared to the total number of knobs. In the exemplary embodiment of the present invention depicted in FIG. **13B**, four (4) adjusters **1312** are provided. Consequently, in the present embodiment, if the value of variable N is less than or equal to the value of four (4), then one or more adjusters **1312** have not yet been processed. Therefore, process **1100** proceeds to **1110** and continues to process the next adjuster (i.e., the adjuster having a variable N value equal to the current value of variable N). Alternatively, if the value of variable N is greater than four (4), then the position of each adjuster **1312** has been read and processed, and process **1100** returns to step **1104**. At **1104**, the value of variable N is reset to zero (0) to allow steps **1104** through **1124** to be repeated for all adjusters **1312** beginning with the adjuster **1312** having a variable N value of one (1).

Next, at step **1110**, the position of the adjuster **1312** corresponding to the current value of N is read. As discussed in greater detail above with regards to FIGS. **13A** and **13B**, in the exemplary embodiment of the present invention depicted herein, each adjuster **1312** is a knob coupled to a dedicated adjuster ADC **1314**, the latter of which is coupled to recorder local control unit **1310**. As a user turns the knob of an adjuster **1312** in a clockwise or counterclockwise direction, the electrical resistance of its variable resistor changes. At step **1110**, adjuster ADC **1314** measures the voltage across each adjuster **1312** and converts it to a numeric digital value. More specifically, adjuster ADC **1314** measures the voltage across a wiper of adjuster **1312** and converts it to a numeric digital value corresponding to the measured level of voltage. This digital value is then read by recorder local control unit **1310**, and it corresponds to the gain desired by the user. However, alternate methods of reading a gain value desired by a user may be substituted without departing from the scope of the present invention. For example, a user may set a desired gain value via a touch screen (i.e., a display screen that is sensitive to the touch of a finger, stylus, or the like). In such an embodiment, since a

touch screen is a digital device, the recorder local control unit may directly read the digital information entered by the user via the touch screen.

In one embodiment of the present invention, the absolute gain able to be set by a particular adjuster **1312** is limited to a range of possible values to prevent an erroneous setting that might severely impact the quality of the audio received from a particular microphone. That is, the position of each adjuster **1312** is limited to a value between an absolute lowest gain and an absolute highest gain. These limits may be incorporated using a plurality of methods. For example, physical stops may be incorporated to prevent an adjuster **1312** from exceeding a predetermined allowed physical rotation. Alternatively, electrical high and low limits may be applied to adjuster ADC to prevent its output from exceeding, or falling below, predetermined limits. Or, recorder local control unit **1310** may be programmed to override a value received from **1314** when it exceeds, or falls below, a predetermined limit. In such a scenario, recorder local control unit **1310** may defer to a pre-programmed fallback value. Other methods may also be substituted without departing from the scope of the present invention.

Process **1100** then proceeds to step **1112**, at which it is determined whether the current adjuster **1312** is set to local or remote trim mode. As discussed above in greater detail, in the depicted embodiment of the present invention, each adjuster **1312** is associated with a respective recorder audio input device port **1318**. When an adjuster **1312** is set to local trim mode, the respective adjuster **1312** is modifying the gain of the audio received from the audio input device connected to its respective audio input device port **1318**. Conversely, when an adjuster **1312** is set to remote trim mode, the respective adjuster **1312** is modifying the gain of the audio received from the audio input device **314** (FIG. **3A**) connected to the local audio device **102** associated with the particular adjuster **1312**.

If step **1112** determines that the current adjuster **1312** is set to remote trim mode, process **1100** proceeds to step **1114**. At step **1114**, the particular adjuster **1312** associated with the current value of N is correlated to a unique local audio device **102**. In our exemplary embodiment of the present invention, the local audio device **102** associated with the adjuster **1312** having the current value of N is simply the local audio device **102** having a unit ID equivalent to the value of N. That is, if the current value of N is one (1), the corresponding adjuster is **1312a** as discussed above and the corresponding local audio device **102** is the one that has a unit ID of one (1). Therefore, when adjuster **1312a** is indexed to remote trim mode, it will remotely adjust the gain of the audio received from audio input device **312** (FIG. **3A**) of the local audio device **102** assigned a unit ID of one (1). Similarly, when the value of N is two (2), the current adjuster is adjuster **1312b**. And, when adjuster **1312b** is indexed to remote trim mode, it will remotely adjust the gain of the audio received from audio input device **312** (FIG. **3A**) of the local audio device **102** assigned a unit ID of two (2) and so on. It should be noted that other methods of correlating an adjuster **1312** to a local audio device **102** may be substituted without departing from the scope of the present invention. Process **1100** then proceeds to **1116**.

At step **1116**, process **1100** combines the absolute value of the gain read from the current adjuster **1312**, the unit ID for the corresponding local audio device **102**, and other information to create a data packet for transmission to the corresponding local audio device **102**. The other information included in the data packet is described in greater detail below with respect to FIG. **12** and the format of an exem-

plary data packet is depicted in FIG. 14. To create the data packet, all required data (See FIG. 14) other than the checksum value is sent to a buffer of recorder 108. Then the checksum value is calculated and appended to the data located in the buffer. The data is then transferred to a buffer of transmitter 208 of RCU 104 (See FIG. 2A).

Next, at step 1118, the data packet generated at step 1116 and contained in the buffer of transmitter 208 is transmitted to the corresponding local audio device 102 (as determined during step 1114). In our exemplary embodiment of the present invention, RCU 104 is wired to timecode port 1320 of recorder 108, and recorder 108 transmits the generated data packet through this wired connection for transmission wirelessly by RCU 104's RCU transmitter 208. The data packet is received wirelessly at the corresponding local audio device 102 via its local receiver 302, and it is processed as discussed in greater detail below with respect to FIG. 12. Alternate embodiments of the present invention are envisioned in which data is transmitted via a different method including, but not limited to, wireless transmission directly from recorder 108 to the corresponding local audio device. Process 1100 then returns to step 1106, at which the value of the variable N is incremented by one (1) and steps 1108 to 1122 are repeated.

If, at step 1112, it is determined that the mode of the current adjuster 1312 is set to local trim mode, process 1100 proceeds to step 1120. On recorder 108, each adjuster 1312 has a corresponding audio input device port 1318. When a particular adjuster 1312 is indexed to local trim mode, it will locally adjust the gain of the audio received from audio input device 1316 (FIG. 13A) connected to the adjuster 1312's corresponding audio input device port 1318. To do this, process 1100 first determines if the absolute value of the gain read from the current adjuster 1312 is different from the current gain value for the corresponding audio input device port 1318 as stored in recorder memory 1308. If the gain read from the current adjuster 1312 is equal to the current gain value stored in recorder memory 1308 (i.e., no change in the gain value has occurred), then process 1100 returns to step 1106, at which the value of the variable N is incremented by one (1) and steps 1108 to 1122 are repeated.

Conversely, if at 1120, the gain read from the current adjuster 1312 is different than the current gain value stored in recorder memory 1308 (i.e., a change in the gain value has occurred), process 1100 proceeds to step 1122. At 1122, the gain value for the corresponding audio input device port 1318 is adjusted to the new value read from the current adjuster 1312. The gain is adjusted via a gain adjustment circuit such as gain adjustment circuit 1326. However, alternate methods of adjusting gain may be substituted without departing from the scope of the present invention. Also, gain may be adjusted incrementally (i.e., in upward and downward steps) rather than absolutely (i.e., setting gain to a specific value) without departing from the scope of the present invention.

Process 1100 then proceeds to 1124, at which the new gain value is stored for comparison with future gain values received at a later time. Process 1200 then returns to 1106, at which the value of the variable N is incremented by one (1) and steps 1108 to 1122 are repeated.

Process 1100 is executed whenever recorder 108 is receiving power via recorder power supply 1306 as described above. In this manner, process 1100 continuously repeats steps 1104 through 1124 in order to continually adjust all incoming audio with the most up-to-date gain values to optimize the quality of the audio recorded via recording system 100.

In our exemplary embodiment, these commands are generated by a user at recorder 108, however, alternate embodiments of the present invention are envisioned in which such commands are generated by another component of recording system 100 such as, but not limited to, mixer 109 as discussed in greater detail below.

Mixer 109 may be any commercially available mixing board such as, but not limited to, Zaxcom, Inc.'s Mix-8 or Mix-12 control surfaces. Such a mixer typically would include, inter alia, a plurality of audio input ports (e.g., microphone input ports), such as input device port 1318, and a plurality of adjusters, such as adjuster 1312 for local adjustment of the gain, or amplification, of audio received via the audio input ports (e.g., from a microphone or the like connected thereto) generated at each local audio device 102. Such a mixer may also include sliding potentiometers for local adjustment of the received audio amplification as is commonly known in the art. Additionally, mixer 109 may have the ability to adjust other qualities of the incoming audio (e.g., equalization, bass, treble, etc.) as is commonly known in the art and typically available with similar commercially available products. For example, mixer 109 may also control equalization of audio from each local audio device 102 to boost a certain range of frequencies (e.g., bass, treble, etc.) for improvement of audio quality.

Referring now to FIG. 12, depicted is a process 1200 for receiving and executing commands at one or more local audio devices 102. Specifically, the exemplary process depicted in FIG. 12 depicts a method for remotely controlling a specific local audio device 102. A process such as exemplary process 1200 is executed by local control unit 310 (See FIG. 3A) of local audio device 102 whenever the device is receiving power via local power supply 306. Process 1200 is executed in sequence with the other processes performed by local control unit 310 as described in greater detail above.

Process 1200 begins at 1202 and proceeds to step 1204. At 1204, all local audio devices 102 are indexed to a unique unit ID. Indexing of a unit ID for a particular local audio device 102 may be performed locally by a user via manipulation of its respective keypad 320 or remotely via an RCU such as RCU 104 as discussed in greater detail above with respect to FIGS. 3A/3B and FIGS. 2A/2B, respectively. As also discussed above, the unit ID identifies the specific one of multiple local audio devices 102 that a user wishes to control. Setting the unit ID to a unique value ensures that the control signals transmitted by recorder 108 are received by the correct and intended local audio device 102. That is, since each adjuster 1312 is assigned to a particular unit ID, recorder 108 is programmed to transmit and gain adjustments performed via a particular adjuster 1312 to the local audio device 102 having the unit ID to which the particular adjuster 1312 has been assigned. Or, alternatively, multiple local audio devices 102 may be assigned an identical unit ID code in order to control several local audio devices 102 with the same commands simultaneously as a group.

Next, process 1200 proceeds to step 1206, at which a specific one of the local audio devices 102 receives a data stream via its local receiver 302 in a manner discussed in greater detail above with reference to FIG. 3B. Although steps 1206 through 1224 will be discussed with respect to a specific one of the local audio devices 102, all local audio devices simultaneously and independently perform these steps in the same manner.

In the embodiment of the present invention depicted in FIGS. 1-15, the data stream received at the local audio device 102 includes a plurality of binary data packets that

are sixteen (16) bytes in length. In one embodiment, the data stream is sent by RCU 104's RCU transmitter 208 (as discussed in greater detail above with respect to FIG. 11) at a rate of 2000 data packets per second via 2.4 GHz RF transmission. However, alternate embodiments of the present invention are envisioned in which the data stream is sent by at a different rate of packets per second and/or a different frequency. Also, although the depicted embodiment of the present invention transmits a data stream from recorder 108, such a data stream may be alternatively created and/or transmitted from other components of recording system 100 including, but not limited to, mixer 109.

At step 1208, process 1200 begins parsing each data packet of the data stream received by local transmitter 308. The data packets are sixteen (16) bytes in length and are comprised of a plurality of 16 bit words. That is, each data packet is a string of binary digits 128 characters in length divided into eight segments that are sixteen (16) bits (i.e., sixteen digits) or two (2) bytes in length. Local control unit 310 parses each segment of sixteen (16) digits as a word. As illustrated in FIG. 14, one exemplary data packet includes eight word lengths of data and each word communicates specific information to local control unit 310 as further discussed below.

Process 1200 then proceeds to 1210, at which it determines if the data packet is a control packet by parsing the first word of the data packet (i.e., word #0). The first word serves as a control word to indicate if the data packet is a control packet or some other packet including, but not limited to, a timecode packet (i.e., a packet utilized to transmit a master timecode between components of recording system 100) or an audio packet (i.e., a packet utilized to transmit audio between components of recording system 100). If all of the bits in word #0 are zero (0), then the data packet is a timecode packet and its purpose is to transmit a master timecode to local audio device 102. If all of the bits in word #0 are one (1), then the data packet is a control packet and its purpose is to remotely control one or more functions of local audio device 102 as described in greater detail herein. Alternatively, if the bits of word #0 are some combination of zeros (0) and ones (1), then the data packet is an audio packet and it is placed in an audio first in first out ("FIFO") queue and sent to a decompression routine. At step 1210, if word #0 of the data packet does not indicate that it is a control packet, process 1200 returns to step 1206 to parse the next data packet in the received data stream and the timecode or audio packet is processed by a separate process (not shown) executed by local control unit 310.

Alternatively, if step 1210 determines that the data packet is a control packet, process 1200 proceeds to step 1212. At step 1212, process 1200 determines whether the data packet is a valid data packet. In the depicted embodiment, the validity of the data packet is verified by reading the eighth word (i.e., word #7) of the data packet. Word #7 includes a checksum value, which is a value used to ensure data within the data packet has been transmitted without error. The checksum value is created by calculating the binary values in a block of data using a predetermined algorithm and storing the result with the data. When the data is received by local audio device 102, process 1200 calculates a new checksum using the same predetermined algorithm and compares the calculated result to the checksum value. If the calculated result does not match the checksum value, an error has occurred that has affected the validity of the data packet. An invalid data packet may occur, for example, if data is lost during RF transmission or if an error occurs in assembly of the data packet by recorder 108. In such a

scenario, process 1200 discards the data packet (i.e., it does not continue processing the data packet and it takes no action relative to the data packet) and returns to step 1206 to parse the next data packet in the received data stream. Alternatively, if, at 1212, the data packet is found to be valid because the calculated result matches the checksum value, process 1200 proceeds to 1214. Although the depicted embodiment of the present invention utilizes a checksum method of validating the data packet, other methods including, but not limited to, the CRC method may be substituted without departing from the scope of the present invention.

At step 1214, process 1200 determines if the data packet is a duplicate data packet that has previously been received and processed by local audio device 102. In the depicted embodiment of the present invention, all control data packets are transmitted two or more times to ensure reception by the intended local audio device 102. For instance, if a control data packet is received with an incorrect check sum as described in the previous step, it is discarded and its command is not processed by local control unit 310. Therefore, multiple transmissions of identical control data packets facilitate the likelihood that the intended local audio device 102 receives and processes all command data packets. Process 1200 incorporates a tag value to identify duplicate data packets. That is, the tag value for each new control data packet is incremented while each duplicate control data packet has an identical tag value to its original control data packet. In the depicted embodiment of the present invention, the third word (i.e., word #2) of each command data packet indicates the tag value. The first nibble of this word is always equal to F and the second nibble of this word is set equal to the tag value. The first nibble of this word is set to F as a placeholder. That is, the value of F simply fills this portion of the word until it takes on a specific purpose in future upgrades of the invention. Process 1200 reads the second nibble (i.e., bits 5-8) of the third word of the control data packet and compares the tag value to the tag value of the previously received control packet. If the tag value of the current control data packet is identical to the tag value of a previously received control data packet, process 1200 discards the control data packet (i.e., it does not continue processing the data packet and it takes no action relative to the data packet) and returns to step 1206 to parse the next data packet in the received data stream. Alternatively, if, at 1214, the data packet is found to be a new control data packet having a different tag value than the previously processed data packet, process 1200 proceeds to 1216. Although the depicted embodiment of the present invention utilizes a tag value method of identifying duplicated control data packets, other methods may be substituted without departing from the scope of the present invention.

At 1218, process 1200 determines if the control data packet includes a command for the specific local audio device 102 processing the control data packet. That is, process 1200 reads the second word (i.e., word #1) of the control data packet to determine the unit ID of the local audio device 102 for which the control data packet is intended. The read unit ID is compared to the unit ID of the local audio device 102 processing the control data packet to determine if they are identical. If yes, the control data packet is intended for the processing local audio device 102 and it is processed. If no, the control data packet is intended for another local audio device 102 and it is discarded. Every data packet received by a single local audio device 102 may not be applicable to that device. For example, if a gain adjustment is made at adjuster 1312b and the local audio device 102 receiving the control data packet is assigned to

adjuster **1312a**, then the control data packet is not intended for that local audio device **102** and it is discarded.

If it is determined that the control data packet is intended for a different local audio device **102** than the one processing the control data packet, process **1200** discards the data packet (i.e., it does not continue processing the data packet and it takes no action relative to the data packet) and returns to step **1206** to parse the next data packet in the received data stream. Alternatively, if, at **1218**, it is determined that the received control data packet is intended for the processing local audio device **102**, process **1200** proceeds to **1220**. Although the depicted embodiment of the present invention utilizes a comparison method of ensuring the received control data packet is intended for the processing local audio device **102**, other methods may be substituted without departing from the scope of the present invention.

Next, at step **1220**, process **1200** determines what type of command is to be performed. Process **1200** determines the type of command by reading the data string contained in the second byte of word #2 through word #6 of the data packet. The data string begins with the command to be performed. For example, if the data string begins with UBCMD_GAIN, then the command is a gain adjustment command. In this scenario, the data following UBCMD_GAIN in the data string indicates the absolute numerical value of the new gain setting, and the data string is null terminated to indicate the end of the string. Once process **1200** has read the type of command present in the data string, process **1200** proceeds to **1222** to further process the command.

At **1222**, the command read in step **1220** is processed. The steps involved in processing the command will vary based upon the type of command. In our exemplary embodiment in which the command is an adjust gain command, the new gain value contained in the data string of the current data packet is compared to the existing gain value stored in memory **332** of the respective local audio device **102**. If the two values are identical, no adjustment is required and process **1200** returns to step **1206** to parse the next data packet in the received data stream. Alternatively, if, at **1222**, it is determined that the new gain value is different from the existing gain value stored in memory **332** of the respective local audio device **102**, the gain value for the respective local audio device **102** is adjusted to the new value received wirelessly in steps **1206** through **1220**. The gain is adjusted by extracting the gain change byte (i.e., the byte of data associated with word #3) from the data string and converting it to a voltage to be transmitted to gain adjustment circuit **1326** as discussed in greater detail above with respect to FIG. **3A**. The voltage to which it is converted may be obtained from a look up table or the like that correlates the value in the gain change byte to a specific voltage that will effect the desired gain change. However, alternate methods of adjusting gain may be substituted without departing from the scope of the present invention. Also, gain may be adjusted incrementally (i.e., in upward and downward steps) rather than absolutely (i.e., setting gain to a specific value) without departing from the scope of the present invention.

After the command received in the data string is processed, process **1200** proceeds to **1224** at which data associated with the processed command, if any, is stored in memory **332**. In our gain adjustment example, the new gain value is stored for comparison with new gain values received at a later time. Process **1200** then returns to **1206** to parse the next data packet in the received data stream.

In the depicted embodiment of the present invention, commands other than a UBCMD_GAIN may be incorporated in a command data packet for receipt and processing

by an intended local audio device **102**. For example, three such commands include the UBCMD_SCENE, UBCMD_TAKE and UBCMD_REEL commands. These commands transmit the name of the scene, the take number, or the reel number from recorder **108** to the intended local audio device **102**. The name of the scene is the title of the scene as determined by a producer or other production personnel. The take number is the numerical designator that identifies the current take being filmed. The reel number indicates the numerical designator that identifies the medium upon which the video being filmed is recorded (e.g., a reel, CD, DVD, etc.). When this information is transmitted to the local audio devices **102**, they can incorporate the data in audio packets to facilitate later identification of the audio packet and/or matching of the audio packet to the appropriate video data. That is, since the video being recorded simultaneously with the audio is labeled with scene, take, and reel identifiers, labeling recorded audio with the same identifiers allows the video and audio to be more easily combined post-recording.

After process **1200** reads a UBCMD_SCENE, UBCMD_TAKE or UBCMD_REEL command at step **1220**, it proceeds to step **1222**, at which it processes this command. Processing of the command includes reading the data that follows the command in the data string to determine the name or number of the scene, take, or reel, respectively. Process **1200** then proceeds to **1224**, at which the read data is saved to memory **332** in a predetermined location associated with the particular data to be saved thereto. Once the data is saved to the predetermined location, process **1200** returns to **1206** to parse the next data packet in the received data stream. Saving of the scene, take, and/or reel data to memory **332** allows the process executed by local control unit **310** in which audio packets are created to retrieve the data during the audio packet creation process for incorporation in the audio packet.

Another exemplary command that may be incorporated in a command data packet for receipt and processing by an intended local audio device **102** is UBCMD_SEGNUM. This command transmits the numerical designator that identifies the audio segment to the intended local audio device **102**. In the depicted embodiment of the present invention, the segment number is assigned in sequential order to each new audio segment, and it may be utilized, for example, for segmentation of large audio files as discussed above with respect to FIGS. **9** and **10**. However, other methods of assigning numerical identifiers may be substituted without departing from the scope of the present invention.

After process **1200** reads a UBCMD_SEGNUM command at step **1220**, it proceeds to step **1222**, at which it processes this command. Processing of the command includes reading the data that follows the command in the data string to determine the segment number. Process **1200** then proceeds to **1224**, at which the read data is saved to memory **332** in a predetermined location associated with the current segment number. Once the data is saved to the predetermined location, process **1200** returns to **1206** to parse the next data packet in the received data stream. Saving of the segment number to memory **332** allows the process executed by local control unit **310** in which audio packets are created to retrieve the data during the audio packet creation process for incorporation in the audio packet.

Yet another exemplary command that may be incorporated in a command data packet for receipt and processing by an intended local audio device **102** is UBCMD_TRANSPORT. This command transmits the transport mode of a local audio device **102** to the intended local audio device

102. In the depicted embodiment of the present invention, the transport mode may be play, record, or stop. The transport mode is determined by a user of audio recorder 108. However, other methods of assigning a transport mode to a local audio device 102 such as, but not limited to, automatically assigning such modes may be substituted without departing from the scope of the present invention.

After process 1200 reads a UBCMD_TRANSPORT command at step 1220, it proceeds to step 1222, at which it processes this command. Processing of the command includes reading the data that follows the command in the data string to determine the whether the transport mode is play, record, or stop. Process 1200 then proceeds to 1224, at which the read data is saved to memory 332 in a predetermined location associated with the current transport mode. Once the data is saved to the predetermined location, process 1200 returns to 1206 to parse the next data packet in the received data stream. Saving of the segment number to memory 332 allows a process executed by local control unit 310 in which transport mode is required to retrieve the data during execution of the process to allow the process to execute in accordance with the current transport mode. Examples of processes in which transport mode data is utilized include, but are not limited to, processes 400, 600 and 700 as described in greater detail above. For instance, step 412 of process 400 determines if the transport value is record and, if so, proceeds with operation of recording system 100 in a synchronous timecode generator mode as discussed in greater detail above with respect to FIG. 4. Similarly, step 712 of process 700 determines if the transport value is record and, if so, proceeds with operation of recording system 100 in asynchronous timecode generator mode as discussed in greater detail above with respect to FIG. 7. A transport mode value of play may be utilized, for example, by process 600 in step 610 to determine if playback of audio has been requested by recorder 108 due to a loss of audio as discussed in greater detail above with respect to FIG. 6.

UBCMD_CHANNEL is another exemplary command that may be incorporated in a command data packet for receipt and processing by an intended local audio device 102. This command transmits the frequency at which the receiving local audio device 102 should operate. In the depicted embodiment of the present invention, this frequency is transmitted as a four digit value. For example, a frequency of 5555 indicates that the desired RF frequency is 555.5 MHz. The desired frequency is determined by a user of recording system 100 based upon the frequency at which the least interference will be encountered. However, other methods of assigning a frequency to a local audio device 102 such as, but not limited to, automatically assigning such frequencies may be substituted without departing from the scope of the present invention.

After process 1200 reads a UBCMD_CHANNEL command at step 1220, it proceeds to step 1222, at which it processes this command. Processing of the command includes reading the data that follows the command in the data string to determine the desired frequency. Local control unit 310 transmits a numerical value corresponding to the desired frequency to a direct digital synthesizer (“DDS”). The DDS compares the received frequency data to the existing frequency at which the local audio device 102 is operating. If they are equal, no change is made. If they vary, the DDS adjusts the frequency at which local transmitter 308 is operating via a phase-locked loop.

Process 1200 then proceeds to 1224, at which the new frequency data is saved to memory 332 in a predetermined

location associated with operating frequency. Once the data is saved to the predetermined location, process 1200 returns to 1206 to parse the next data packet in the received data stream.

Yet another exemplary command that may be incorporated in a command data packet for receipt and processing by an intended local audio device 102 is UBCMD_IFBMIX. This command transmits the ration of amplification of remotely and locally received audio. In the depicted embodiment of the present invention, this ratio is the amplification of locally received audio (i.e., audio received via audio input device port 314 divided by the amplification of remotely received audio (i.e., audio received via local receiver 302 such as audio received from RCU 104 as described in greater detail above). This amplification ratio is adjusted by a user of recording system 100. However, other methods of adjusting the amplification ratio such as, but not limited to, automatically assigning such ratio may be substituted without departing from the scope of the present invention.

After process 1200 reads a UBCMD_IFBMIX command at step 1220, it proceeds to step 1222, at which it processes this command. Processing of the command includes reading the data that follows the command in the data string to determine the amplification ratio. Process 1200 then proceeds to 1224, at which the read data is saved to memory 332 in a predetermined location associated with the amplification ratio. Once the data is saved to the predetermined location, process 1200 returns to 1206 to parse the next data packet in the received data stream. Saving of the amplification ratio to memory 332 allows a process executed by local control unit 310 in which the level of amplification of remotely generated audio is adjusted relative to the level of amplification of locally generated audio.

Turning now to FIGS. 16-18, depicted are processes 1600 and 1700 and circuitry 1800 for automatically adjusting the power output of one or more local audio devices such as local audio devices 102 described above. It may be advantageous to make such power output adjustments for a variety of reasons including, but not limited to: reduction in the size, weight, and/or heat produced by a local audio device; elimination or minimization of health risks to a wearer of the local audio device (such as those caused by exposure to the heat generated by the device when worn and/or constant body exposure to high power radio frequency waves); reduction in RF emissions; reduction in interference between a plurality of local audio devices (due to reducing the power output of those devices not in use, thereby eliminating or minimizing their ability to interfere with in use devices); and conservation of battery power/life due to decreased power consumption.

FIG. 16 depicts a process for automatically creating and transmitting high and low power commands used to adjust the power output of one or more local audio devices. Process 1600 begins at 1602, at which a system such as system 100 is in the process of recording as described above. In the exemplary embodiment described herein, process 1600 is executed by a control unit such as recorder control unit 1310 as described above with respect to FIGS. 13A and 13B. However, alternate embodiments of the present invention are envisioned in which process 1600 is executed by hardware, a combination of hardware and software, and/or by a component of system 100 other than recorder 108.

After 1602, process 1600 proceeds to step 1604, at which the status of the record mode is queried. In the depicted embodiment, the internal record status of a recorder such as recorder 108 is queried to determine if is currently recording. Initiation and cessation of recording may be performed

by a user in any one of a variety of ways including, but not limited to, a local control panel integral to the recorder and via a remote control unit such as, for example, remote control unit **104** as described above with reference to FIGS. **2A** and **2B**. In the depicted embodiment, recording is enabled or disabled by indexing switches (e.g., the flat illuminated pushbuttons **1313e** and **1313g** as discussed above with respect to FIG. **13B**) to recording or non-recording mode. The status of the switch is read directly by the recorder's local control unit (e.g., recorder control unit **1310**).

If process **1600** determines that the recorder is not currently recording, process **1600** proceeds to **1606**, at which it generates a low power command to be transmitted to all local audio devices. The low power command may be encoded for transmission along with other commands and/or audio data via a data packet (e.g., the data packet depicted in FIG. **14** as discussed above) or it may be a dedicated command sent individually (e.g., in the form of the data packet depicted in FIG. **14** as discussed above). In embodiments in which all of the local audio devices are switched to low or high power, the low power command may simply notify the local audio device that the recorder is not in record mode. Compatible local audio devices are pre-programmed to read this record status and index themselves to low power mode as discussed below. It is important to note that low power may be any power level less than the current high power level including, but not limited to, zero power. Conversely, high power may be any power level higher than the current low power level.

Process **1600** then proceeds to **1608**. In the depicted embodiment, the low power command(s) are transmitted to all local audio devices via an RF transmitter. The RF transmitter may be integral to the recorder or it may be integral to another device coupled to the recorder, for example, a receiver such as receiver **106**. However, alternate embodiments are envisioned in which the low power command(s) are transmitted in a manner other than RF including, without limitation, via a hardwired link or via a non-RF transmitter. Also, alternate embodiments are envisioned in which low power command(s) are sent to a predetermined subset of the local audio devices rather than all local audio devices.

Alternatively, if at **1604**, it is determined that the recorder is recording, process **1600** proceeds to **1614** at which process **1600** then queries the recording status of one, all, or some subset of the local audio devices (e.g., local audio devices **102**) that are a part of the recording system (e.g., system **100**). In one embodiment of the present invention, this query is performed by determining status parameters within the recorder to determine which local audio devices are currently recording. For example, if an event being recorded has (4) individuals each equipped with his or her own dedicated local audio device, the final recording will have four (4) audio inputs recorded by the recorder. However, the number of individuals in any given scene or portion of the event may be less than four (4). In a scene in which, for example, only two (2) individuals are being recorded, the recorder is manually programmed to record two inputs rather than four inputs. In such a scenario, the local audio devices that are not being recorded may be indexed to low power.

In the exemplary embodiment of the present invention, the record status for each track is determined via an audio input/output routing table, wherein each input is associated with a particular local audio device. The association of inputs to local audio devices is typically a 1:1 ratio, and it

is programmed by a sound engineer or the like at the recorder prior to recording. In such embodiments, whether a local audio device is in recording mode may be determined by querying the input/output routing table to determine whether the input associated with the local audio device is being routed to an output. If yes, the local audio device is determined to be in recording mode. If the input is not being routed to an output, then the local audio device associated with that input is determined to not be in recording mode. However, alternate methods of determining the recording status of each local audio device may be substituted without departing from the scope of the present invention.

At step **1614**, process **1600** reads the actual tracks being recorded for the particular scene or portion of the event to identify those local audio devices in use for the particular scene/portion. This allows the high power command created in step **1616** to be sent only to those local audio devices currently utilized, which allows the local audio devices that are not in use for that scene to remain at low power. Allowing unused local audio devices to remain at low power has many advantages including, but not limited to: elimination or minimization of interference and/or intermodulation; reduction in the size, weight, and/or heat produced by a local audio device; elimination or minimization of health risks to a wearer of the local audio device; reduction in RF emissions; reduction in interference between a plurality of local audio devices; and conservation of battery power/life. Intermodulation is the undesirable mixing of RF signals that is typically caused by receiver overload (or recorder overload in cases in which the receiver is integral to the recorder). Intermodulation is minimized or eliminated since the signals at low power are less likely to mix with the signals indexed to high power. Furthermore, interference is reduced by eliminating or minimizing RF communication between the recorder transmitter (or the transmitter of a receiver coupled to the recorder) and all local audio devices whose audio tracks are not currently being recorded.

In an alternate embodiment, process **1600** determines the local audio devices to be set to high power (i.e., those currently recording) by polling the devices via one or more commands sent via RF transmission or the like. Such commands may query the record status or other status of the local audio device to determine whether to index the local audio device to high or low power. Or, in more complicated embodiments, specific data relevant to power requirements of the local audio device may be stored in one or more registers of the local audio device for query by process **1600**. That is, local audio device may be specifically programmed to direct the recorder as to the optimal power requirement as determined by the other operating parameters of the local audio device, which allows the recorder software to create a command specific to the local audio device to direct it to its optimum performance level.

In yet another simplified alternate embodiment, step **1614** may be eliminated. In such an embodiment, only the record status of the recorder is queried without regard for which audio inputs are being individually recorded and/or which local audio devices are being recorded. In this embodiment of the invention, all local audio devices are commanded to high power whenever the recorder is in record mode (i.e., any or all inputs are being recorded by the recorder as determined at step **1604**). In such an embodiment, the high and low power commands broadcast the record status of the recorder (i.e., disabled or enabled), and the local audio devices are programmed to automatically read the recorder's record status and adjust their power to low (when recording is disabled) or high (when recording is enabled).

Once process **1600** has determined which local audio devices will receive a high power command, process **1600** proceeds to **1616** at which the high power command(s) are generated. The high power command may be encoded for transmission along with other commands and/or audio data via a data packet (e.g., the data packet depicted in FIG. **14** as discussed above) or it may be a dedicated command sent individually via a data packet or the like (e.g., in the form of the data packet depicted in FIG. **14** as discussed above). In embodiments in which all of the local audio devices are switched to low or high power, the high power command may simply notify the local audio device that the recorder is in record mode. Compatible local audio devices are pre-programmed to read this record status and index themselves to high power mode as discussed below. Also, in embodiments of the present invention in which less than all of the local audio devices may receive a high power command, the command may be packaged with a local audio device identifier such as a unit identification number or the like. This allows each local audio device to determine whether a specific high (or low) power command is intended for that specific local audio device.

Process **1600** then proceeds to step **1608**, at which the generated high power command(s) are transmitted to the local audio devices for processing by those local audio devices selected in step **1614**. Step **1608** is described in greater detail above. However, alternate simpler embodiments are also envisioned in which all local audio devices are sent high power command(s) whenever the recorder is in recording mode.

After step **1608**, process **1600** returns to **1604** and again queries the record status of the recorder. That is, process **1600** continually runs during the operation of a system such as system **100** to continuously and dynamically adjust the power outputs thereof for maximum efficiency. This also ensures that any local audio devices that have been indexed to low power output are immediately indexed back to high power output if the audio input associated with those local audio devices is switched to recording mode by a sound engineer or other user of the recorder.

In the exemplary embodiment discussed herein, a user may index a recorder such as recorder **108** to one of three modes: enable automatic power control feature (i.e., allow power to be dynamically adjusted between low and high as described herein with respect to FIGS. **16-18**); index all local audio devices to high power (i.e., all local audio devices are indexed to high power by, for example, repeating steps **1616** and **1608** as described above without regard for recording status); and index all local audio devices to low power (i.e., all local audio devices are indexed to low power by, for example, repeating steps **1606** and **1608** as described above without regard for recording status). This allows a user to either manually control the power of the local audio devices via a recorder or to allow the recorder to automatically and dynamically adjust the local audio devices to low or high power.

Process **1700** depicts a process for receiving and processing a low or high power command at a local audio device such as local audio device **102**. In the exemplary embodiment described herein, process **1700** is executed by a control unit such as local control unit **310** as described above with respect to FIGS. **3A** and **3B**. However, alternate embodiments of the present invention are envisioned in which process **1700** is executed by hardware and/or a combination of hardware and software.

Process **1700** starts at **1702**, at which a low or high power command is received from an external device such as a

recorder, remote control unit, or the like. Next, at **1704**, the low or high power command is processed. In the exemplary embodiment, the command is received via a local receiver such as local receiver **302** as described above with respect to FIGS. **3A** and **3B**, and it is decoded via a local control unit such as local control unit **310**, as also described above with respect to FIGS. **3A** and **3B**, to determine the necessary power level adjustments.

Next, at **1706**, the power output of the local audio device is adjusted. In the depicted embodiment, this is implemented by adjusting amplifier operating parameters including, but not limited to, voltage levels (e.g., bias and source voltage levels) and/or RF drive levels. One such method of adjusting these parameters is described below with respect to FIG. **18**. Turning now to FIG. **18**, depicted is an exemplary embodiment of a portion of a local transmitter circuit **1800** in accordance with one embodiment of the present invention. Transmitter circuit **1800** includes, inter alia, transistor **1802**, which receives analog audio from the local audio device's local control unit (e.g., local control unit **310**) after it has been converted to analog form by transmitter DAC **1812**. In one exemplary embodiment, transmitter DAC **1812** is a MAX1850 high speed DAC as manufactured by Maxim Integrated Products. However, other compatible digital to analog converters may be substituted without departing from the scope hereof.

Transistor **1802** amplifies the audio received from transmitter DAC **1812** and outputs same at point RF_{out} **1806**. In the exemplary embodiment depicted in FIG. **18**, transistor **1802** is a pseudomorphic High Electron Mobility Transistor ("pHEMT"); however, other compatible transistors or RF amplifier chips may be substituted. Also, in this exemplary embodiment, capacitors **1814**, **1816**, **1820**, **1822**, **1824**, **1828**, **1830**, **1832**, and **1834** have a fixed capacitance of 0.1 uF, 100 uF, 100 pF, 100 pF, 0.01 uF, 100 pF, 0.01 uF, 100 pF, and 10 uF, respectively, and resistor **1838** has a resistance of 20 ohms. The remaining capacitors, inductors, and resistors, namely capacitor **1826**, inductor **1838**, inductor **1840**, and inductor **1842** are initially set during manufacture to values of 100 pF, 22 nH, 12 nH, and 82 nH, respectively. Subsequently, during calibration of transmitter circuit **1800**, each of these values is modified as necessary to achieve an RF output of approximately 17+ dBm when in low power mode and approximately 21+ dBm when in high power mode. That is, the values of capacitor **1826**, inductor **1838**, inductor **1840**, and inductor **1842** of transmitter circuit **1800** are individually adjusted for each local audio device to achieve the correct dBm output levels as further discussed below. In this exemplary embodiment, low and high power commands may index the incoming analog audio signal received from transmitter DAC **1812** to approximately 4 dBm in high power mode and approximately 0 dBm in low power mode. That is, the local audio device's local control unit adjusts the level of the audio signal created by transmitter DAC **1812** via direct control of the parameters of transmitter DAC **1812** by local control unit **310**.

Additionally, in the depicted embodiment, high and low power commands may index the input voltage at V_D **1810** to approximately 4.5V in high power mode and to approximately 3.5V in lower power mode. Low and high power commands may also index the gate voltage applied to point V_g **1808** to approximately 0.5 V in high power mode and approximately 0.7 V in low power mode. Adjustment of the voltage output of the input voltage at V_D **1810** and the gate voltage at point V_g **1808** in combination with the factory calibrated values of capacitor **1826**, inductor **1838**, inductor **1840**, inductor **1842**, and resistor **1834** allow low and high

power commands to achieve an RF output of +21 dBm in high power mode and +17 dBm in low power mode. That is, when the components of transmitter amplification circuit are properly calibrated, the resulting value of the dBm RF output at **1806** is +17 dBm for low power mode and 21+ dBm for high power mode.

These values stated above are merely exemplary and alternate values may be substituted without departing from the scope hereof.

Turning now to FIG. **19**, depicted is an alternate embodiment of a process **1900** for automatically creating and transmitting high and low power commands used to adjust the power output of one or more local audio devices. Process **1900** begins at **1902**, at which a system such as system **100** is in the process of recording as described above. In the exemplary embodiment described herein, process **1900** is executed by a control unit such as recorder control unit **1310** as described above with respect to FIGS. **13A** and **13B**. However, alternate embodiments of the present invention are envisioned in which process **1900** is executed by hardware, a combination of hardware and software, and/or by a component of system **100** other than recorder **108**.

After **1902**, process **1900** proceeds to step **1904** at which the channel variable "CH" is set to equal zero. Next, at step **1906**, process **1900** increments the current value of the CH variable by one. Next, at step **1908**, process **1900** determines if the value of the channel variable is greater than the total number of available channels. In the depicted embodiment, recorder **108** has the ability to record eight (8) channels or inputs. Additionally, each local audio device is assigned a channel identification number from one (1) to eight (8). Each value of the channel variable (i.e., 1, 2, 3, 4, 5, 6, 7, and 8) is associated with the recorder channel and local audio device having the same value. For example, when the value of the channel variable is 1, the process is generating low or high power commands for the local audio device that is assigned a channel identification number of 1. That is, as further discussed below, process **1900** uses the value of the channel variable to continually generate specific high or low power commands for each local audio device associated with the current channel. While the depicted embodiment includes eight (8) recording channels, alternate embodiments of the present invention are envisioned in which a greater or lesser number of recording channels may be substituted without departing from the scope thereof. Also, methods of selecting a local audio device other than a channel variable may be substituted.

As is further discussed below, as process **1900** is executed, steps **1906** through **1918** are repeated multiple times. Therefore, step **1908** is necessary to determine if the value of the channel variable has reached a value greater than the total number of available channels. In the depicted embodiment, if step **1908** of process **1900** determines that the value of the channel variable is greater than eight (8), then process **1900** returns to step **1904**, at which the channel variable is set to zero.

Alternatively, if at **1908** the value of the channel variable is not greater than eight, process **1900** proceeds to step **1910** at which the recording status of the local audio device associated with the current channel variable value is queried to determine if it is enabled for recording on the master recorder. In one embodiment, this is done by querying the recorder to determine if the channel is routed to an output as discussed above with respect to FIG. **16**. However, other methods of determining recording status may be substituted without departing from the scope of the present invention.

If, at **1910**, the status of the current local audio device is not enabled, process **1900** proceeds to **1914**, at which it generates a low power command to be transmitted to the local audio device associated with the current channel value.

The low power command may be encoded for transmission along with other commands and/or audio data via a data packet (e.g., the data packet depicted in FIG. **14** as discussed above) or it may be a dedicated command sent individually (e.g., in the form of the data packet depicted in FIG. **14** as discussed above).

Process **1900** then proceeds to **1918**. In the depicted embodiment, the low power command is transmitted to the current local audio device via an RF transmitter. The RF transmitter may be integral to the recorder or it may be integral to another device coupled to the recorder, for example, a receiver such as receiver **106**. However, alternate embodiments are envisioned in which the lower power command(s) are transmitted in a manner other than RF including, without limitation, via a hardwired link or via a non-RF transmitter. Also, alternate embodiments are envisioned in which low power command(s) are sent to a predetermined subset of the local audio devices rather than to all local audio devices.

Alternatively, if step **1910** determines that the recording status of the local audio device associated with the current channel variable value is enabled as discussed above, process **1900** proceeds to step **1912**, at which the status of the recorder is queried. In the depicted embodiment, the internal record status of a recorder such as recorder **108** is queried to determine if it is currently recording. Initiation and cessation of recording may be performed by a user in any one of a variety of ways including, but not limited to, a local control panel integral to the recorder and via a remote control unit such as, for example, remote control unit **104** as described above with reference to FIGS. **2A** and **2B**. In the depicted embodiment, recording is enabled or disabled by indexing switches (e.g., the flat illuminated pushbuttons **1313e** and **1313g** as discussed above with respect to FIG. **13B**) to recording or non-recording mode. The status of the switch is read directly by the recorder's local control unit (e.g., recorder control unit **1310**).

If process **1900** determines that the recorder is not currently recording, process **1900** proceeds to **1914**, at which it generates a low power command to be transmitted to the local audio device associated with the current channel value as discussed above.

Alternatively, if at **1912**, it is determined that the recorder is recording, process **1900** proceeds to **1916** at which the high power command is generated. The high power command may be encoded for transmission along with other commands and/or audio data via a data packet (e.g., the data packet depicted in FIG. **14** as discussed above) or it may be a dedicated command sent individually via a data packet or the like (e.g., in the form of the data packet depicted in FIG. **14** as discussed above).

Process **1900** then proceeds to step **1918**, at which the generated high power command is transmitted to the current local audio device for processing. Step **1918** is described in greater detail above.

After step **1918**, process **1900** returns to **1906** and again increments the channel variable by one. This allows the local audio device indexed to the next greater channel number to be indexed to high or low power mode. Process **1900** continually runs during the operation of a system such as system **100** to continuously and dynamically adjust the power outputs thereof for maximum efficiency. This also ensures that any local audio devices that have been indexed

to low power output are immediately indexed back to high power output if the audio input associated with those local audio devices is switched to recording mode by a sound engineer or other user of the recorder. Although several processes have been disclosed herein as software, it is appreciated by one of skill in the art that the same processes, functions, etc. may be performed via hardware or a combination of hardware and software. Similarly, although the present invention has been disclosed with respect to wireless systems, these concepts may be applied to hardwired systems and hybrid hardwired and wireless systems without departing from the scope of the present invention.

It will be appreciated by those skilled in the art that changes could be made to the embodiments described above without departing from the broad inventive concept thereof. It is understood, therefore, that this invention is not limited to the particular embodiments disclosed, but it is intended to cover modifications within the spirit and scope of the present invention as defined by the appended claims.

We claim:

1. A method of recording and transmitting audio comprising the steps of:

providing at least one local audio device wearable by a creator of locally generated audio, the device comprising:

an audio input port configured to couple to an audio input source for receiving the locally generated audio;

a timecode input port configured to receive a plurality of master timecodes from a master timecode generator;

a memory;

a local timecode generator for generating a plurality of local timecodes;

a local control unit electronically coupled to the audio input port, the timecode input port, the memory, and the local timecode generator, the local control unit operable to create a local file including the locally generated audio and at least one of the plurality of local timecodes and to store the local file in the memory, the local control unit operable to synchronize the local timecode generator to the master timecode generator;

an output device configured to output audio, the output audio identical to, substantially identical to or derived from the locally generated audio; the output device electronically coupled to at least one of the group consisting of: the audio input port, the local control unit, and combinations thereof; and

controlling the at least one local audio device to create and store the local file in the memory and to communicate the output audio via the output device.

2. A method according to claim 1, further comprising the steps of:

dynamically adjusting the power level of the local audio device, wherein a remote recorder is equipped to remotely record said locally generated audio via the steps of:

querying at least one status of said remote recorder, said at least one status associated with said local audio device;

generating a command based upon said at least one status;

transmitting said command to said local audio device wearable by said creator of said locally generated audio; and

processing of said command by said local audio device, said processing including adjusting at least one parameter of said local audio device.

3. The method of claim 1, wherein the output device includes an output port or a transmitter.

4. The method of claim 1 further comprising the step of: coupling a wireless transmitter to the output device.

5. The method of claim 1, wherein the output audio includes analog audio that is not digitally converted by the local control unit.

6. The method of claim 1, wherein the local control unit processes the locally generated audio, and the output audio includes the processed locally generated audio in digital or analog form.

7. The method of claim 1, wherein the local control unit stores the local file in memory and communicates the output audio substantially simultaneously.

8. The method of claim 1, wherein the local file includes at least one identifier selected from the group consisting of track identifiers, local audio device identifiers, performer identifiers, and combinations thereof.

9. The method of claim 1, wherein the timecode includes at least one of the group consisting of time data, frame data, timecode type, recorder transport status, name of scene, name of take, track identifier, and combinations thereof.

10. The method of claim 1, wherein the timecode is SMTPE timecode.

11. The method of claim 1, wherein the at least one local audio device includes a gain adjustment circuit, the gain adjustment circuit separate from or at least partially implemented by the local control unit.

12. The method of claim 1, wherein the at least one of the plurality of local timecodes is stored in a header of the local file.

13. The method of claim 1, wherein the output audio is transmitted to at least one of the group consisting of a receiver, a recorder, a mixer, and combinations thereof for creation of a remote file.

14. The method of claim 1, wherein the memory is removable.

15. The method of claim 1, wherein the synchronize the speed of the local timecode generator to the speed of the master timecode generator is performed via varying the input applied to at least one of the group consisting of a clock control input of an oscillator, a sample rate of a local ADC, and combinations thereof.

16. The method of claim 1, wherein the at least one local audio device further comprises:

a local ADC; and

wherein the synchronize the speed of the local timecode generator to the speed of the master timecode generator is performed via varying at least one of the group consisting of: the speed of the local timecode generator; the sampling rate of the local ADC; and combinations thereof.

17. At least one audio device wearable by a user for storing locally generated audio and transmitting the locally generated audio to a remote device, the remote device including at least one of a receiver, a recorder, a mixer, and combination thereof, the at least one audio device comprising:

a wireless transmitter,

an audio input port configured to couple to an audio input device to receive the locally generated audio;

a memory;

a local timecode generator operable to generate a local timecode;

45

a control unit coupled to the wireless transmitter, the audio input port, the memory, and the local timecode generator, the control unit operable to: (i) receive a master timecode from a master timecode generator and jam synchronize the local timecode generator to the master timecode generator using the master timecode, (ii) transmit the locally generated audio to the remote device via the wireless transmitter; and (iii) store the locally generated audio in the memory as audio data; and (iv) stamp at least a portion of the audio data with the local timecode.

18. The at least one audio device of claim 17, wherein the control unit stores the locally generated audio in the memory and transmits the locally generated audio to a remote device substantially simultaneously.

19. The method of claim 18, wherein the at least one of the group consisting of a receiver, a recorder, and combinations thereof is not worn by a creator of locally generated audio and is located remotely from the at least one local audio device.

20. The method of claim 18 further comprising:
removing the memory from the at least one local audio device;
retrieving the local file from the memory;
repairing corruption of the remote file using the local file retrieved from the memory.

21. The at least one audio device of claim 17, wherein the audio data includes at least one identifier selected from the group consisting of track identifiers, local audio device identifiers, performer identifiers, and combinations thereof.

22. The at least one audio device of claim 17, wherein at least one of the group consisting of the local timecode, the master timecode, and combinations thereof includes at least one of the group consisting of time data, frame data, type, recorder transport status, name of scene, name of take, track identifier, and combinations thereof.

23. The at least one audio device of claim 17, wherein at least one of the master timecode, the local timecode, and combinations thereof is SMPTE compliant timecode.

24. The audio device of claim 23, wherein the locally generated audio is communicated from the audio input port to the control unit via an audio pathway, the control unit being configured to also receive the master timecode from the master timecode generator via the audio pathway.

25. The audio device of claim 24, wherein the control unit is further operable to stamp the audio data with user-definable information, the user-definable information including information identifying at least one of a scene and a take.

26. The audio device of claim 25, wherein the control unit is operable to store the audio data in the memory within a broadcast .WAV file.

27. The audio device of claim 25, wherein the control unit is further operable to establish a dedicated communication channel with the receiver or the recorder.

28. The audio device of claim 27, wherein the wireless transmitter, the memory, the local timecode generator, and the audio input port are housed in a body pack.

29. The audio device of claim 27, wherein the body pack does not include a receiver.

30. The audio device of claim 25, wherein the control unit is further operable to store non-audio information related to the locally generated audio, the control unit storing only the locally generated audio and the non-audio information in the memory.

46

31. The audio device of claim 25, further comprising: a local preamp coupled to the audio input port; and a local analog-to-digital converter coupled to the local preamp and to the control unit, wherein a time reference received by the local timecode generator and a sampling signal received by the analog-to-digital converter are derived from a high-speed clock.

32. The audio device of claim 25, wherein the portion of the audio data stamped with the local timecode is less than all of the audio data.

33. The at least one audio device of claim 17 further comprising: a gain adjustment circuit, the gain adjustment circuit separate from or at least partially implemented by the control unit.

34. The at least one audio device of claim 17, wherein at least one of the local timecode is stored with said audio data.

35. The audio device of claim 17, wherein the memory is removable.

36. The audio device of claim 17, wherein the jam synchronize the the local timecode generator to the master timecode generator is performed via varying the input applied to at least one of the group consisting of: a clock control input of an oscillator, an input of the local timecode generator; a sample rate of a local ADC, and combinations thereof.

37. The audio device of claim 17, wherein the at least one audio device further comprises:

a local ADC; and

wherein the synchronize the local timecode generator to the master timecode generator is performed via varying at least one of the group consisting of: the speed of the local timecode generator; the sampling rate of the local ADC; and combinations thereof.

38. The audio device of claim 17 further comprising: an output device configured to output audio, the output audio substantially identical to or derived from the locally generated audio, the output device electronically coupled to one of the group consisting of: the audio input port, the control unit, and combinations thereof.

39. The at least one audio device of claim 38, wherein the output audio includes analog audio that is not digitally converted by the control unit.

40. The method of claim 17, wherein the at least one local audio device further comprises:

a local ADC; and

wherein the synchronize the speed of the local timecode generator to the speed of the master timecode generator is performed via varying at least one of the group consisting of: the speed of the local timecode generator; the sampling rate of the local ADC; and combinations thereof.

41. The method of claim 38 wherein the at least one of the group consisting of a receiver, a recorder, a mixer, and combinations thereof is located remotely from the at least one local audio device and operates to create a multi-track remote file including the local files received from all of the at least one local audio device.

42. The method of claim 39 further comprising:
removing the memory from the at least one local audio device;
retrieving the local file from the memory;
repairing corruption of the remote file using the local file retrieved from the memory.

43. The method of claim 39 further comprising:
adjusting at least one characteristic of the file received from the at least one audio device prior to creation of said remote file.

47

44. The at least one audio device of claim 38, wherein the control unit processes the locally generated audio, and the output audio includes the processed locally generated audio in digital or analog form.

45. The at least one audio device of claim 38, wherein the output device includes an output port or a transmitter.

46. The at least one audio device of claim 38, wherein the output device is configured to couple to a wireless transmitter.

47. The at least one audio device of claim 38, wherein the output audio is transmitted to the remote device for creation of a remote file.

48. The method at least one audio device of claim 47, wherein the user is a performer, the remote device is not worn by the performer or any other performer, and the remote device is located remotely from the at least one audio device.

49. The at least one audio device of claim 47 wherein the remote device is located remotely from the at least one audio device and operates to create a multi-track remote file including the locally generated audio received from all of the at least one audio device.

50. The at least one audio device of claim 49, wherein the remote device is not worn by a creator of locally generated audio.

51. The audio device of claim 38, wherein the control unit is operable to receive commands remotely from a wireless remote control unit.

52. The audio device of claim 51, wherein the commands include a command to adjust microphone gain.

53. The audio device of claim 52, wherein the control unit receives audio from the wireless remote control unit.

54. The audio device of claim 53, wherein the locally generated audio is communicated from the audio input port to the control unit via an audio pathway, the control unit being configured to also receive the master timecode from the master timecode generator via the audio pathway.

55. The audio device of claim 54, wherein the control unit is further operable to stamp the audio data with user-definable information, the user-definable information including information identifying at least one of a scene and a take.

56. The audio device of claim 55, wherein the control unit is operable to store the audio data in the memory within a broadcast .WAV file.

57. The audio device of claim 55, wherein at least one of the master timecode and the local timecode is an SMPTE compliant timecode.

58. The audio device of claim 57, wherein the portion of the audio data stamped with the local timecode is less than all of the audio data.

59. An audio device wearable by a user for storing locally generated audio and communicating the locally generated audio to a wireless transmitter for transmission of the locally generated audio to a remote device, the remote device including at least one of a receiver and a recorder, the audio device comprising:

a memory;

a local timecode generator operable to generate a local timecode;

an audio input port configured to couple to an audio input device to receive the locally generated audio; and

a control unit coupled to the memory, the local timecode generator and the audio input port, the control unit being operable to (i) receive a master timecode from a master timecode generator and jam synchronize the local timecode generator to the master timecode gen-

48

erator using the master timecode, (ii) communicate the locally generated audio to the wireless transmitter for transmission of the locally generated audio to the remote device, (iii) store the locally generated audio in the memory as audio data; and (iv) stamp at least a portion of the audio data with the local timecode.

60. The audio device of claim 59, wherein at least one of the master timecode and the local timecode is an SMPTE compliant timecode.

61. The audio device of claim 60, wherein the locally generated audio is communicated from the audio input port to the control unit via an audio pathway, the control unit being configured to also receive the master timecode from the master timecode generator via the audio pathway.

62. The audio device of claim 61, wherein the control unit is further operable to stamp the audio data with user-definable information, the user-definable information including information identifying at least one of a scene and a take.

63. The audio device of claim 62, further comprising: a local preamp coupled to the audio input port; and a local analog-to-digital converter coupled to the local preamp and to the control unit, wherein a time reference received by the local timecode generator and a sampling signal received by the analog-to-digital converter are derived from a high-speed clock.

64. The audio device of claim 63, wherein the control unit is operable to store the audio data in the memory within a broadcast .WAV file.

65. The audio device of claim 63, wherein the portion of the audio data stamped with the local timecode is less than all of the audio data.

66. The audio device of claim 59, wherein the control unit is operable to receive commands remotely from a wireless remote control unit.

67. The audio device of claim 66, wherein the commands include a command to adjust microphone gain.

68. The audio device of claim 67, wherein the control unit receives audio from the wireless remote control unit.

69. The audio device of claim 68, wherein the locally generated audio is communicated from the audio input port to the control unit via an audio pathway, the control unit being configured to also receive the master timecode from the master timecode generator via the audio pathway.

70. The audio device of claim 69, wherein the control unit is further operable to stamp the audio data with user-definable information, the user-definable information including information identifying at least one of a scene and a take.

71. The audio device of claim 70, further comprising: a local preamp coupled to the audio input port; and a local analog-to-digital converter coupled to the local preamp and to the control unit, wherein a time reference received by the local timecode generator and a sampling signal received by the analog-to-digital converter are derived from a high-speed clock.

72. The audio device of claim 71, wherein the control unit is operable to store the audio data in the memory within a broadcast .WAV file.

73. The audio device of claim 71, wherein at least one of the master timecode and the local timecode is an SMPTE compliant timecode.

74. The audio device of claim 73, wherein the portion of the audio data stamped with the local timecode is less than all of the audio data.

49

75. A recording system, comprising:
 a remote device, the remote device including at least one
 of a receiver and a recorder; and
 an audio device, including
 a wireless transmitter,
 a memory,
 a local timecode generator operable to generate a local
 timecode;
 an audio input port configured to couple to an audio input
 device to receive the locally generated audio, and
 a control unit coupled to the wireless transmitter, the
 memory, the local timecode generator and the audio
 input port, the control unit being operable to (i) receive
 a master timecode from a master timecode generator
 and jam synchronize the local timecode generator to the
 master timecode generator using the master timecode,
 (ii) transmit the locally generated audio to the remote
 device via the wireless transmitter, (iii) store the locally
 generated audio in the memory as audio data; and (iv)
 stamp at least a portion of the audio data with the local
 timecode, the audio data being retrievable from the
 memory post-recording,
 wherein the remote device is configured to permit an
 operator to correct for dropouts or interference in the
 locally generated audio transmitted to the remote
 device using the audio data retrieved from the memory
 post-recording.

76. The recording system of claim **75**, wherein at least one
 of the master timecode and the local timecode is an SMPTE
 compliant timecode.

77. The recording system of claim **76**, wherein the locally
 generated audio is communicated from the audio input port
 to the control unit via an audio pathway, the control unit
 being configured to also receive the master timecode from
 the master timecode generator via the audio pathway.

78. The recording system of claim **77**, wherein the control
 unit is further operable to stamp the audio data with user-
 definable information, the user-definable information
 including information identifying at least one of a scene and
 a take.

79. The recording system of claim **78**, wherein the audio
 device further includes:

a local preamp coupled to the audio input port; and
 a local analog-to-digital converter coupled to the local
 preamp and to the control unit, wherein a time refer-
 ence received by the local timecode generator and a
 sampling signal received by the analog-to-digital con-
 verter are derived from a high-speed clock.

80. The recording system of claim **79**, wherein the control
 unit is operable to store the audio data in the memory within
 a broadcast .WAV file.

81. The recording system of claim **79**, wherein the audio
 device is operated by a performer and the remote device is
 operated by a remote user.

82. The recording system of claim **77**, wherein the control
 unit is operable to receive commands remotely from a
 wireless remote control unit.

83. The recording system of claim **82**, wherein the com-
 mands include a command to adjust microphone gain.

84. The recording system of claim **83**, wherein the control
 unit receives audio from the wireless remote control unit.

85. The recording system of claim **84**, wherein the locally
 generated audio is communicated from the audio input port
 to the control unit via an audio pathway, the control unit
 being configured to also receive the master timecode from
 the master timecode generator via the audio pathway.

50

86. The recording system of claim **85**, wherein the control
 unit is further operable to stamp the audio data with user-
 definable information, the user-definable information
 including information identifying at least one of a scene and
 a take.

87. The recording system of claim **86**, wherein the control
 unit is operable to store the audio data in the memory within
 a broadcast .WAV file.

88. The recording system of claim **86**, wherein at least one
 of the master timecode and the local timecode is an SMPTE
 compliant timecode.

89. The recording system of claim **88**, wherein the portion
 of the audio data stamped with the local timecode is less than
 all of the audio data.

90. The recording system of claim **89**, wherein the audio
 device further includes:

a local preamp coupled to the audio input port; and
 a local analog-to-digital converter coupled to the local
 preamp and to the control unit, wherein a time refer-
 ence received by the local timecode generator and a
 sampling signal received by the analog-to-digital con-
 verter are derived from a high-speed clock.

91. A method of using a recording system, comprising:
 employing an audio device, the audio device including
 a control unit,

a wireless transmitter,
 a memory,

a local timecode generator operable to generate a local
 timecode, and

an audio input port coupled to the control unit, the
 audio input port configured to couple to an audio
 input device to receive locally generated audio for
 communication to the control unit,

jam synchronizing the local timecode generator to a
 master timecode generator using a master timecode
 received from the master timecode generator;

operating the audio device to transmit the locally gener-
 ated audio to a remote device via the wireless trans-
 mitter, the remote device including at least one of a
 receiver and a recorder;

operating the audio device to generate audio data repre-
 senting the locally generated audio;

operating the audio device to stamp at least a portion of
 the audio data with the local timecode;

operating the audio device to store the audio data in the
 memory;

retrieving the audio data from the memory post-recording;
 and

using the audio data post-recording to correct for dropouts
 or interference in the locally generated audio transmit-
 ted to the remote device.

92. The method of claim **91**, wherein at least one of the
 master timecode and the local timecode is an SMPTE
 compliant timecode.

93. The method of claim **92**, wherein the locally generated
 audio is communicated from the audio input port to the
 control unit via an audio pathway, the control unit being
 configured to also receive the master timecode from the
 master timecode generator via the audio pathway.

94. The method of claim **93**, wherein the control unit is
 further operable to stamp the audio data with user-definable
 information, the user-definable information including infor-
 mation identifying at least one of a scene and a take.

95. The recording system of claim **94**, wherein the audio
 device further includes:

51

a local preamp coupled to the audio input port; and a local analog-to-digital converter coupled to the local preamp and to the control unit, wherein a time reference received by the local timecode generator and a sampling signal received by the analog-to-digital converter are derived from a high-speed clock.

96. The method of claim 95, wherein the control unit is operable to store the audio data in the memory within a broadcast .WAV file.

97. The method of claim 95, wherein the portion of the audio data stamped with the local timecode is less than all of the audio data.

98. The method of claim 91, wherein the control unit is operable to receive commands remotely from a wireless remote control unit.

99. The method of claim 98, wherein the commands include a command to adjust microphone gain.

100. The method of claim 98, wherein the control unit receives audio from the wireless remote control unit.

101. The method of claim 100, wherein the locally generated audio is communicated from the audio input port to the control unit via an audio pathway, the control unit being configured to also receive the master timecode from the master timecode generator via the audio pathway.

52

102. The method of claim 101, wherein the control unit is further operable to stamp the audio data with user-definable information, the user-definable information including information identifying at least one of a scene and a take.

103. The method of claim 102, wherein the control unit is operable to store the audio data in the memory within a broadcast .WAV file.

104. The method of claim 102, wherein at least one of the master timecode and the local timecode is an SMPTE compliant timecode.

105. The method of 104, wherein the portion of the audio data stamped with the local timecode is less than all of the audio data.

106. The recording system of claim 105, wherein the audio device further includes:

a local preamp coupled to the audio input port; and a local analog-to-digital converter coupled to the local preamp and to the control unit, wherein a time reference received by the local timecode generator and a sampling signal received by the analog-to-digital converter are derived from a high-speed clock.
