(57) **ABSTRACT**

A recommender engine is configured to access memory and surface transmedia content items; and/or linked transmedia content subsets; and/or one or more identifications of identified users; and/or content items of the plurality of transmedia content items associated with at least one identified user. The surfaced items are presented for selection by the given user via the transmedia content linking engine as one or more user-selected transmedia content items.

RECOMMENDER ENGINE AND USER MODEL FOR TRANSMEDIA CONTENT DATA

FIELD OF DISCLOSURE

The present disclosure relates to an apparatus, system and method for processing transmedia content data. For example, the disclosure provides for identifying and surfacing recommendations of transmedia content to users for processing of transmedia content, and additionally the disclosure also provides for user modelling of users accessing transmedia content data.

BACKGROUND

Influenced by a variety of different multimedia content types, new digital distribution channels, mobile communication devices and an ever increasing use of social media, industry is currently experiencing a disruption in how media is created, distributed and consumed. Classical production pipelines have become less effective as audiences move towards anytime, anywhere, personalized consumption, substituting TV-centric models with multi-device, multichannel models. Individual customers and groups of customers have also become more interactive and participatory, contributing significantly to the creation of new media. The cycles in the traditional creation-distribution-consumption loop become much shorter as consumers constantly provide feedback, resulting in a trend towards ultrashort form content.

Existing delivery platforms, for example YouTube and Facebook, allow for the creation and editing of simple channel based content, using a basic model whereby content creators can upload content such as video, text or images, and users can consume the content in an isolated, linear and mono-medial manner. This can often be done in conjunction with media presented via other platforms such as television or print media.

At the same time, functionality provided by existing multimedia platforms allows the sharing of user-generated content, which, along with social networking, is transforming the media ecosystem. Mobile phones, digital cameras and other pervasive devices produce huge amounts of data that users can continuously distribute in real time. Consequently, content sharing and distribution needs will continue to increase. The content can be of many different forms, known collectively as "transmedia" content.

Existing systems that allow users to generate, organize and share content are generally hard to control: these systems do not offer adequate tools for predicting what the next big trend will be, and which groupings of time-ordered content resonate with particular audiences. Furthermore, visualising the large amount of multimedia information in a way which users can explore and consume is challenging. In particular, visualisation of such large data sets is challenging in terms of performance, especially on lower-power devices such as smartphones or tablets. It is desirable that any visualisation of the data could be rendered in real time such that immediate visual feedback is provided to a user exploring the data.

The ever-growing availability of content to multiple users and the ever-increasing power of computing resources available to individual users is driving users towards their own individual creation of content, with such content being in multiple formats. This progression can be seen in FIG. 1. User 10 consumes single content items 15. With increasing computing resources, user 20 has developed into an inter-

2

active user making choices which affect the flow of individual content items 25 to the user 20. Further, user 30 has recently become more common by generating multiple personalised, individual content items 35 which can be accessed over the Internet 50 by other users. A problem now exists with a current user 40 who can access a considerable amount of different types of content items 35 over the Internet 50 and desires to utilise such content. It would be desirable for user 40 to be able to contribute to and generate new structured groups 46 of linked content items 45.

In utilising the content items 35, the amount of which can be considerable, it can be problematic for the user 40 to be able to readily identify relevant and appropriate content for placing into the new structured groups 46. Such content can additionally be identified by considering the content generated from other users. However, it can be equally problematic to identify the users who might be similar to user 40, and thereby themselves be generating relevant and appropriate content.

SUMMARY OF THE DISCLOSURE

In a first aspect of this disclosure, there is provided an apparatus for surfacing transmedia content to a given user of a plurality of users comprising:

a memory configured to store:

a plurality of transmedia content items, each content item being associated with at least one of the plurality of users; and

linking data which define time-ordered content links between the plurality of transmedia content items, the plurality of transmedia content items being arranged into linked transmedia content subsets comprising different groups of the transmedia content items and different content links therebetween;

a transmedia content linking engine configured to receive user input indicative of a time-ordering between at least two user-selected transmedia content items and generate the content link data for storage in the memory, thereby defining a linked transmedia content subset including the at least two user-selected transmedia content items; and

a recommender engine configured to access the memory and surface to the given user: one or more content items of the plurality of transmedia content items; and/or one or more of the linked transmedia content subsets of the linked transmedia content subsets; and/or one or more identifications of identified users other than the given user; and/or the content items of the plurality of transmedia content items associated with at least one identified user other than the given user,

wherein the one or more surfaced content items and/or the one or more surfaced linked transmedia content subsets are surfaced for selection by the given user via the transmedia content linking engine as one or more user-selectable transmedia content items.

The apparatus thus provides for transmedia content, whether individual items, subset groups thereof, or owners associated thereto, to be readily identified and surfaced so that a given user can utilise such content within their apparatus, even if it is associated with other users, for example by linking it to other content in a time-ordered fashion.

The apparatus may be implemented as a computing device, for example a server computing device.

The memory may further include or be configured to store user ownership data which associates each transmedia con-

tent item to a user of the plurality of users, and each transmedia content subset of the multiple content subsets with a user of the plurality of users.

The transmedia content linking engine may be configured to identify a current user-selected time-ordered location of the given user within a given linked transmedia content subset for insertion of one of the transmedia content items, and to generate corresponding content linking data therefor upon insertion by the given user of the one or more content items into the given linked transmedia content subset.

The recommender engine may be further configured to surface the one or more transmedia content items and/or surface the one or more transmedia content subsets based on the current user-selected time-ordered location.

The apparatus may further comprise a preference model, wherein the preference model is configured to generate a user-specific rating (or score) for a given user for a given transmedia content data item.

The preference model can be configured to:

remove global effects for one or more rated items that have been previously rated by the given user to generate explicit ratings (user-assigned ratings) and storing the removed global effects;

provide the explicit ratings and metadata associated with the given transmedia content data item to a plurality of recommender algorithms to generate a plurality of predicted ratings for the given transmedia content data item;

combine the plurality of predicted ratings to build an ensemble prediction of the predicted ratings for the given transmedia content data item;

add the stored global effects to the ensemble prediction to produce a predicted user rating for the given transmedia content data item; and

output the predicted user rating for the given transmedia content data item.

The user assigned ratings previously assigned by individual users may be stored as metadata alongside each content item, or linked content subset. The user assigned ratings may be extracted by a metadata extraction component and fed to the preference model.

The apparatus may further comprise a user-brand match component configured to provide for a given user a prediction of a preference for a given branded content data item.

The apparatus may further comprise a branded content model configured to provide for a given transmedia content item a prediction of the suitability of a given branded content data item.

The recommender engine may be further configured to surface transmedia content data items by querying the preference model, user-brand match component and brand model component by providing the preference model, user-brand match component and brand model with a transmedia content parameter, user data for the given user and a given branded content data item, and to maximise the sum of the output for the preference model, user-brand match component and brand model over the transmedia content parameter.

The recommender engine may be configured to surface the transmedia content data item with the maximum output.

The plurality of transmedia content items may comprise items of different content types.

The transmedia content data items may relate to narrative elements of the transmedia content data items. The time-ordered content links can define a narrative order of the transmedia content data items. Each time-ordered content link can define a directional link from a first transmedia

content data item to a second transmedia content data item of the plurality of transmedia content data items.

The first transmedia content data item may have a plurality of outgoing time-ordered content links. The second transmedia content data item may have a plurality of incoming time-ordered content links.

The memory can be further configured to store a plurality of subset entry points for the plurality of transmedia content subsets. Each subset entry point may be a flag indicating a transmedia content data item that has at least one outgoing time-ordered link and no incoming time-ordered links. Each linked transmedia content subset can define a linear path, wherein the linear path comprises a subset entry point, one or more transmedia content data items and one or more time ordered links between the subset entry point and the transmedia content data items. Two or more transmedia content subsets can share one or more subset entry points, one or more transmedia content data items and/or one or more time ordered content links.

The recommender engine can be further configured to surface one or more group's transmedia content subsets to the given user, the one or more surfaced groups being surfaced for selection by the given user via the transmedia content linking engine.

The apparatus may further comprise a user model, wherein the user model can be configured to provide predictions of the state and/or behaviour of a given user to the recommender engine.

The memory may be further configured to store a plurality of historical user interaction data items which define the historical interaction of a given user with the apparatus for surfacing transmedia content to a given user of a plurality of users, and wherein the user model may be configured to:

receive one or more historical user interaction data items associated with the given user;

provide the one or more historical interaction data items to a statistical model to produce a prediction of a mental state of the user;

retrieve from the statistical model the predicted mental state of the user and/or a predicted behaviour of the user; and

output the predicted mental state of the user and/or predicted behaviour of the user.

The statistical model may be a hidden Markov model.

The transmedia content recommender engine may be further configured to surface the one or more individual content items to the given user and/or surface one or more of the linked transmedia content subsets to the given user when the output of the user model indicates that the user is in a mental state conducive to consuming transmedia content data items.

The transmedia content recommender engine can be further configured to surface the one or more individual content items to the given user and/or surface one or more of the linked transmedia content subsets to the given user when the output of the user model indicates the predicted user behaviour is to consume transmedia content data items.

In a second aspect of the present disclosure, there is provided a system for surfacing transmedia content to a given user of a plurality of users comprising:

the aforementioned apparatus;

an electronic device configured to be in communication with the apparatus and receive and display to the given user: the surfaced one or more content items of the plurality of transmedia content items; and/or the surfaced one or more linked transmedia content subsets of the linked transmedia content subsets; and/or the surfaced one or more identifica-

5

tions of identified users other than the given user; and/or the surfaced content items of the plurality of transmedia content items associated with at least one identified user other than the given user.

In a third aspect of the present invention, there is provided A method for surfacing transmedia content to a given user of a plurality of users from a memory configured to store a plurality of transmedia content items, each content item being associated with at least one of the plurality of users, and linking data which define time-ordered content links between the plurality of transmedia content items, the plurality of transmedia content items being arranged into linked transmedia content subsets comprising different groups of the transmedia content items and different content links therebetween, the method comprising:

receiving, at a transmedia content linking engine, user input indicative of a time-ordering between at least two user-selected transmedia content items;

generating with the transmedia content linking engine the content linking data for storage in the memory, thereby defining a linked transmedia content subset including the at least two user-selected transmedia content items; and

accessing the memory and surfacing to the given user with a recommender engine: one or more content items of the plurality of transmedia content items; and/or one or more of the linked transmedia content subsets of the linked transmedia content subsets; and/or one or more identifications of identified users other than the given user; and/or the content items of the plurality of transmedia content items associated with at least one identified user other than the given user,

wherein the one or more surfaced content items and/or the one or more surfaced linked transmedia content subsets are surfaced for selection by the given user via the transmedia content linking engine as one or more user-selectable transmedia content items.

The electronic device may be implemented as user equipment, which may be a computing device, for example a client computing device, such as personal computer, laptop or a handheld computing device. For example, the handheld computing device may be a mobile phone or smartphone. The electronic device may include a user input interface configured to provide user input to the processing circuitry, such as for example the instructions to create a new time-ordered content link. This may be one or more of a keypad or touch-sensitive display. The electronic device may include a display (which may include the touch-sensitive display) configured to output data to a user interacting with the electronic device, including one or more of the content data items.

In a fourth aspect of the present invention, there is provided a computer readable medium comprising computer executable instructions, which when executed by a computer, cause the computer to perform the steps of the aforementioned method.

BRIEF DESCRIPTION OF DRAWINGS

The present invention is described in exemplary embodiments below with reference to the accompanying drawings in which:

FIG. 1 depicts how users interact with content items according to the present disclosure.

FIGS. 2A, 2B and 2C depict a linear transmedia content subset, grouped non-linear transmedia content subsets, and

6

a subset universe respectively, each formed of multiple transmedia content data items and time-ordered content links.

FIG. 3 depicts the architecture of the system of the present disclosure.

FIG. 4 depicts an exemplary apparatus on which the backend of the present disclosure operates.

FIG. 5 depicts an exemplary apparatus on which the frontend of the present disclosure operates.

FIG. 6 depicts exemplary non-linear networks of transmedia content data items according to the present disclosure.

FIG. 7 depicts a recommender engine of the apparatus of the present disclosure.

FIG. 8 depicts an exemplary preference model component of the recommender engine component according to the present disclosure.

FIG. 9 depicts a user model component of the apparatus of the present disclosure.

FIGS. 10A and 10B depict exemplary user interfaces that are rendered and output by the system.

FIG. 11 depicts how user state and actions can be modelled according to the system.

FIG. 12 depicts a method for surfacing transmedia content to a user according to the present disclosure.

DETAILED DISCLOSURE

The present disclosure describes a new apparatus, system and method for managing transmedia content. In one embodiment, there is disclosed a platform for the creation, distribution and consumption of transmedia content. The content may be arranged in a time-ordered manner for consumption, thereby defining so-called “story” based content.

In the context of the present disclosure, groups of time-ordered content, for example in the form of stories, are made up of multiple elements of transmedia content, each being referred to herein as a transmedia content data items. Each item pertains to a narrative element of the story. Each transmedia content data item may be linked, and thus connected, to one or more other transmedia content data items in an ordered fashion such that a user can navigate through subsets of the transmedia content data items (also referred to as transmedia content subsets) in a time-ordered fashion to consume some or all of an entire story.

The term “transmedia” means that the grouped content data items (which are linked within the content subsets) comprise a plurality of different multimedia types, e.g. at least two different types of multimedia content. For example, the different types of transmedia content data of each content data item within the subset can comprise at least two different types from one or more of the following: textual data, image data, video data, audio data, animation data, graphical visualization or UI data, hypertext data, gaming data, interactive experience data, virtual reality (VR) data, augmented reality data, and multisensory experience data. Each transmedia content data item may itself comprise multiple media types, e.g. video and audio data may be present within a single item such that the audio is time-associated associated with the video.

The transmedia content data items can be grouped into transmedia content subsets. Each subset may be grouped based on one or more non-linear network of the content data items.

Within each transmedia content subset, transmedia content data items are linked to one another, directly or indirectly, by time-ordered links between each data item. Typi-

cally, each time ordered-content link links two transmedia content data items. An exception exists for a time ordered link which connects a subset entry point and a transmedia content data item as explained below. The time-ordered link also defines a direction between the two transmedia content data items. The direction indicates an order in which linked transmedia content data items should be presented to a user of the system. For example, when a first transmedia content data item is presented to a user, at least one outgoing time-ordered link (i.e. the direction defined by the link is away from the first transmedia content data item) indicates a second transmedia content item that should be presented to the user next.

The term “subset” is used to denote a subset of transmedia content data items within the set of all transmedia content data items stored by the system. The transmedia content data items that are part of a transmedia content subset are all directly or indirectly connected to each via time-ordered content links between the transmedia content data items. A transmedia content subset may be a linear, i.e. each transmedia content data item in the subset has at most one incoming time-ordered content link and one outgoing time-ordered content link, or a non-linear network, i.e. one or more of the constituent transmedia content data items has more than one incoming or outgoing time-ordered content link. It will also be appreciated a non-linear network of transmedia content data items can be considered to be made up of multiple overlapping linear paths from start-point to end-point through that network, and that each linear path may also be considered to be a transmedia content subset. Furthermore, the term “group” has been used to denote a collection of transmedia content data items that are not necessarily connected, directly or indirectly, via time-ordered content links. However, where the term “group” has been used, a “subset” of transmedia content data items, as defined above, may additionally be formed and utilised.

Each time-ordered link is stored in memory as link data comprising: the input content data item; and the output content data item and thus implicitly a direction between two content data items. Directional data for the links is also stored which defines the path the links should be processed, and thus the order for processing of transmedia content items. The order can also be dependent on user interaction with each item as it is surfaced to a user.

Examples of transmedia content subsets are depicted in FIGS. 2A, 2B and 2C. As mentioned above, the transmedia content data items are grouped into transmedia content subsets.

In FIG. 2A, subset **100** defines a linear path of transmedia content data items **104a-c**. The subset **100** also comprises a subset entry point **102**, which defines a starting point in the subset from which the system can commence presenting the transmedia content data items within the subset. The subset entry point **102** may be linked to the first transmedia content data item **104a** by a time-ordered link, or may be a flag associated with the first transmedia content data item **104a** which indicates that the transmedia content data item **104a** is the first in the subset.

In the context of the present disclosure, the term “linear” means that each transmedia content data item has, at most, only one incoming time-ordered line (i.e. the direction defined by the link is inwards towards the transmedia content data item) and only one outgoing time-ordered link. The path defined by the transmedia content subset **100** is unidirectional and there is only one possible route from the subset entry point **102** and the final transmedia content data

item of the path (i.e. a transmedia content data item with an incoming time-ordered link but no outgoing time ordered link).

The transmedia content data items may also be grouped based on multiple content subsets in a non-linear network, such as non-linear network **110** depicted in FIG. 2B. In this context, the term “non-linear” means that time-ordered links between the data items of each network may form a plurality of different paths through the network **110** which start in different places, end in different places, branch, split, diverge, leave some data items out of the path and/or overlap with other paths. Such a non-linear network **110** can also be considered to be a group of transmedia content subsets which share one or more transmedia content data items and/or time-ordered content links.

In the depicted non-linear network **110**, each transmedia content data item **104a-c**, **112a-b** can have one or more incoming time-ordered links and one or more outgoing time-ordered links. The data items **112a**, **104b** and **112b** form a second transmedia content subset which shares the data item **104b** with the first transmedia content subset **100**.

FIG. 2C depicts a story universe **120**, in which multiple, related non-linear networks are grouped or clustered together. In one embodiment, the non-linear networks of a story universe do not share transmedia content data items and/or time-ordered links with the non-linear networks of another, different story universe. However, in an alternative embodiment, the non-linear networks of a story universe do share one or more transmedia content data items and/or time-ordered links with the non-linear networks of another, different story universe.

The system of the present disclosure manages the transmedia content data items, transmedia content subsets and one or more non-linear networks, facilitates the generation and manipulation of items between and within subsets and networks so that storylines can be formed. Accordingly, the creation of transmedia content subsets and non-linear networks by a user of the system enables collaboration between users of the system and allows consumption of the created storylines. The architecture of the system is depicted in FIG. 3.

FIG. 3 depicts the overall architecture of the system **200**. The system **200** includes a frontend device **210**, which is typically located on a user device such as a smartphone, tablet or PC that is operated directly by the user of the system **200**, and a backend device **230**, which is typically located on one or more servers that are connected to the user device via a network such as the Internet.

The backend **230** contains global resources and processes that are managed, stored and executed at a central location or several distributed locations. The frontend **210** contains resources and processes that are stored and executed on an individual user device. The backend **230** is responsible for tasks that operate on large amounts of data and across multiple users and stories, while the frontend **210** only has access to the resources of a particular user (or a group of users) and focuses on presentation and interaction.

The frontend **210** communicates with the backend **230** via the network, the communication layer **212** that is part of the frontend **210** and the experience control layer **232** that is part of the backend **230**. The experience control layer **232** is responsible for handling the distribution of transmedia content data items, access limitations, security and privacy aspects, handling of inappropriate content data items, and user-specific limitations such as age group restrictions. It ensures that inappropriate, illegal, unlicensed or IP-violating content is flagged and/or removed, either automatically,

semi-automatically or manually. It also handles sessions as the user interacts with the system and provides session specific contextual information, including the user's geolocation, consumption environment and consumption device, which can then be used by the frontend **210** to adapt the consumption experience accordingly. The experience control layer **232** also acts as a checkpoint for content validation, story verification, and story logic, in order to provide users with a consistent story experience.

The communication layer **212** performs client-side checks on permissions, content validation, and session management. While the final checks happen at the experience control layer **232** of the backend **230**, the additional checks carried out in the communication layer **212** help in providing a consistent experience to the user (e.g. not displaying content or features that cannot be accessed).

The frontend **210** also includes the user interface (UI) component **220**, which is responsible for displaying and presenting the transmedia content data items to users, including visual, auditory and textual representations, and is also responsible for receiving the user's input through pointing devices, touch events, text input devices, audio commands, live video, or any other kind of interaction. The UI component **218** can adapt to the user's location, environment, or current user state in order to provide an optimized experience.

The visual navigation component **214** is also included in the frontend **210**, and allows a user to explore, browse, filter and search the transmedia content data items, transmedia content subsets and non-linear networks, and any other content provided by the platform. For navigation in the context of transmedia content and stories, the visual navigation component **214** provides intelligent abstractions and higher-level clusterings of transmedia content data items, transmedia content subsets and non-linear networks, providing the user with an interface for interactive visual exploration of the transmedia content, which enables the user to make navigation choices at a higher-level abstraction before exploring lower levels, down to single stories, i.e. transmedia content subsets, and individual transmedia content data items. The structure of transmedia content subsets and non-linear network and the time-ordered links between transmedia content data items data items is visualized as well, providing the user with information on how these data items are related to each other. In one embodiment of this visualisation, a graph structure is employed, with nodes representing transmedia content data items, and connections representing the time-ordered content links. In the main, the evolution of the transmedia content subsets and non-linear networks is rendered in real-time as the subsets and non-linear networks are created and modified by all users of the system. In addition, in a particular embodiment which is user initiated, for example via user selection or automatically based on user interaction, e.g. immediately or shortly after a given user logs in to the system, the recent past evolution of the transmedia content subsets and non-linear networks, e.g. the evolution since last login of the given user can be displayed graphically, e.g. in a time lapse rendering of the changes of the transmedia content subsets and non-linear networks in the order in which they occurred.

The social interaction component **216** handles visualisations and user input related to interactions between individual users of the system **200**. It provides tools for editing a user's public information, enabling notifications on other users creating content (following), endorsing and rating other users' content, and directly interacting with other users through real-time messaging systems, discussion boards,

and video conferencing. These tools also allow users to collaboratively create new content (i.e. transmedia content data items) and author and edit stories (i.e. transmedia content subsets and/or non-linear networks), as well as define the access rights and permissions associated with such collaborative work. The enforcement of these rights is handled by the experience control layer **232**, as mentioned above.

In addition to the experience control layer **232**, the backend **230** comprises a user model component **234**, a story model component **236**, a recommender engine **238**, and a metadata extraction component **240**, in addition to one or more data stores or computer memory for storing data related to the transmedia content such as the transmedia content data items, linking data, transmedia content subsets, non-linear networks, and metadata relating to the individual data items and linking data as well as to the subsets and non-linear networks.

The user model component **234** represents user behaviour and properties. It is driven by a suite of algorithms and data collections, including but not limited to statistics, analytics and machine learning algorithms operating on user interaction patterns, consumption behaviour and social interactions. The analytics happens in real-time and the user model component **234** is continuously updated as the user interacts with the system **200**. Additional information such as the user's geolocation can be taken into account as well. The corresponding data is stored in a user database. The user model component **234** also comprises models for groups of several users, which for example emerge during multiuser collaboration, consumption, geolocation, or social interactions. As part of the user model component **234**, users and/or groups of users are profiled and characterized according to their personality, productivity stage and other criteria. The user model component allows the system to make predictions of user behaviour under real or hypothetical conditions, which then feed into the recommender engine component **238**. The methods employed by the user model component for prediction user behaviour and creative state are described below in more detail with respect to FIG. **9**. The user model component **234** also permits the correlation of interaction patterns of users not identified to the system so as to re-identify users probabilistically.

The user model component **234** is also connected to the talent harvest component, which, based on user behaviour, identifies individual users or groups of users that fulfil certain criteria such as, for example, having a large amount of users consuming or endorsing their work, having significant influence on other users' behaviours and opinions, or being highly popular personalities. The talent harvest component, in concert with the recommender engine component **238**, then influences the behaviour of such users of the system **200**.

The story model component **236** characterises the content of single transmedia content data items, transmedia content subsets, non-linear networks and whole story universe, and stores the corresponding data in a story world database. The characterisations are found through algorithms such as, but not limited to, metadata extraction, analytics, graph analysis, or any other algorithms operating on connections between content in general. Metadata extraction extends to include visual, auditory or textual elements, as well as higher-level concepts like characters, character personality traits, actions, settings, and environments. The characterisation also takes into account how users interact with the content, including the analysis of consumption patterns, content ratings and content-related social interaction behaviour. The corre-

sponding updates of the story model component **236** happen in real-time as users interact with the system **200** or as new content is created or existing content is modified. Additionally, the story model component **236** makes use of story, characterisations (including metadata) to model story logic. Using story reasoning, the consistency of individual stories can be verified and logical inconsistencies can be prevented either when a story is created or at the time of consumption. The story model component **236** also communication with the story harvest component, which uses the data provided by the story model component **236** in order to identify and extract content (transmedia media content data items, transmedia content subsets, non-linear networks or higher-level abstractions).

The recommender engine component **238** is in communication with both the story model component **236** and the user model component **234** and provides conceptual connections between the story model component **236** and the user model component **234**. The recommender engine component **238** uses data analytics to match content (transmedia content data items, transmedia content subsets, non-linear networks) with users, suggesting users for collaboration, suggesting content to be consumed, or suggesting stories, story arcs or story systems to be extended with new content. Recommendations can be explicit, with recommendations being explicitly labelled as such to the user, guiding the user through a transmedia content subset or non-linear by providing an optimal consumption path or suggesting other users to collaborate with, or they can be implicit, meaning the user's choice is biased towards certain elements of content (including transmedia content, advertisement, users), without making the bias explicitly visible to the user.

The metadata extraction component extracts metadata from transmedia content (i.e. transmedia content data items, transmedia content subsets and/or non-linear networks) automatically, semi-automatically, or manually. The metadata extraction component **240** tags and annotates transmedia content, providing a semantic abstraction not only of the content of individual transmedia content data items, but also of the time-ordered links, transmedia content subsets, non-linear networks, and story systems. The derived metadata thus spans a horizontal dimension (cross-domain, covering different types of media) as well as a vertical one (from single transmedia content data items to whole story systems).

Also depicted in FIG. **3** are story world database **280**, media (content) database **282** and user database **284**. The databases **280-284** are stored in memory **301** of server device **230**. The story world database **280** stores data characterising and defining the structure of the transmedia content subsets, non-linear networks and whole story systems, for example by way of linking data defining the subset structure. Additionally, metadata and graph analytics pertaining to the subsets and networks may also be stored in the story world database **280**. The media database **282** stores individual content items, and data characterising the content of individual transmedia content data items, e.g. metadata and graph analytics for the individual content items. The user database **284** stores user data pertaining to users of the system **200**, including user behaviour data defining how users have interacted with individual content items and subsets, and user preference data defining user indicated or derived preferences for content items and subsets.

FIG. **4** depicts an exemplary backend server device **230** on which the backend of the system **200** is implemented. It will be appreciated that the backend **230** or functional components thereof may be implemented across several

servers or other devices. The server device **230** includes the memory **301**, processing circuitry **302** and a network interface **303**. The memory may be any combination of one or more databases, other long-term storage such as a hard disk drive or solid state drive, or RAM. As described above, the memory **301** stores the transmedia content data items and associated linking data, which define time-ordered content links between the plurality of transmedia content data items. The plurality of transmedia content data items are arranged into linked transmedia content subsets comprising different groups of the transmedia content data items and different content links therebetween. The processing circuitry **302** is in communication with the memory **301** and is configured to receive instructions from a user device via the network interface to create new time-ordered content links between at least two of the plurality of transmedia content data items and modify **301** the linking data stored in the memory to include the new time-ordered content link.

FIG. **5** depicts an exemplary frontend electronic user device **210** on which the frontend of system **200** is provisioned. The user device **210** includes a memory **401**, processing circuitry **402**, network interface **403** and a user interface **404**. The user interface **404** may comprise one or more of: a touch-sensitive input, such as a touch-sensitive display, a touchscreen, pointing device, keyboard, display device, audio output device, and a tablet/stylus. The network interface **403** may be in wired or wireless communication with a network such as the Internet and, ultimately, the server device **230** depicted in FIG. **4**. The electronic device **210** receives user input at the user interface **404** and thereby communicates with the server device **230** via the network interface **403** and network interface **303**, which provides the processor **302** with instructions to create new time-ordered content links between the transmedia content data items in the memory **301**. The electronic device **210** may also provide instructions to the server device **230** to delete or modify existing time-ordered content links and/or transmedia content data items from the memory.

It will be appreciated that the system may comprise multiple frontend electronic devices **210**, each configured to receive user input and thereby communicate with the server device **230** and provide instructions to create, delete or modify time-ordered content links between the transmedia content data items. Thus, multiple electronic devices **210**, each being accessed by a different user, are adapted to process common content links and content data items which are accessible to multiple users.

The memory **301** of the server device **230** may also store user data items, which are associated with users of the system **200** and comprise user identification data, such as a username, password, email address, telephone number and other profile information. The user data items may also comprise, for each user of the system user preference data pertaining to each user's preferences, user behaviour data pertaining to the each user's online behaviours, user interaction data pertaining to the each user's interaction with other users, and/or user location data pertaining to the current determined and/or past determined location of the each user.

The server device **230** may also be configured to implement the user model **234** of the system **200** as mentioned above as described below in further detail with respect to FIG. **9**. The processing circuitry **302** of the device **230** can use the user model **234** to identify user interactions of the users of the system **200** with the transmedia content data

items and subsequently update the user interaction data stored in the memory 301 in accordance with the user interaction.

The memory 301 may also store content characterisation data items, which characterise one or more of the transmedia content data items. In particular, the memory 301 may store auditory characterisation data which characterises auditory components the transmedia content data items, visual characterisation data which characterises visual components of the transmedia content data items, textual characterisation data which characterises textual components of the transmedia content data items and/or interaction characterisation data which characterises interactive components, such as games, or quizzes, or puzzles, of the one or more transmedia content data items. The processing circuitry 303 of the server device 230 can be further configured to provide a content subset modelling engine that processes the content characterisation data items for each transmedia content data item in a given transmedia content subset and generates unique subset characterisation data for the transmedia content subset based on the processed characterisation data. The content subset modelling engine may be provided by the story model component 236 mentioned above.

The processing circuitry 302 may also implement the transmedia content recommender engine 238, mentioned above and described below in more detail with respect to FIG. 7. The recommender engine 238 is configured to process the characterisation data items and the user data items for a given user and identify transmedia content data items and surface identification(s) of one or more of the transmedia content data items that are predicted to be matched to users, and additionally can surface identification(s) of other matched users of the system 200.

The processing circuitry 302 of the server device is also configured to implement the experience control layer 232 mentioned above. The experience control layer 232 implements a permission control system which is used to determine whether a given user has permission to view, edit, modify or delete a given transmedia content data item, time-ordered content like, transmedia content subset or non-linear network. Collaboration is a challenge in itself; however, authorship attribution and consistency in particular are supported. A balance is then provided between a very rigid and tight permission system, which might hinder collaboration and discourage potential contributors from sharing their ideas, and an open system which allows any user to modify or delete the content contributed by other users.

For a given transmedia content subset or non-linear network, created by an original first user (referenced hereinafter as "Alice"), and which consists of individual transmedia content data items connected by time-ordered content links therebetween, this transmedia content subset or non-linear network is attributed to and owned by Alice in metadata associated with the transmedia content data items, linking data and the original transmedia content subset and/or non-linear network exclusively. The experience control layer 232 only allows modifications to the original transmedia content subset or non-linear network by Alice. The system 200 is also configured such that a system administrator user or moderator user can provide or change permissions for and between all individual users, regardless of permissions assigned by individual users.

A second user (referenced hereinafter as "Bob") may wish to contribute to the transmedia content subset or non-linear network. Bob may wish to insert a new transmedia content data item into the transmedia content subset or non-linear

network, and/or Bob may wish to create new linking data that defines an alternative path through the non-linear network or transmedia content subset.

The experience control layer 232 does not permit Bob to modify the original transmedia content subset or non-linear network that are attributed to and owned by Alice in the metadata. Instead, the experience control layer 232 instructs the processor 302 to create a copy of the original transmedia content subset or non-linear network in the memory 301, which includes the changes to the transmedia content data items and/or linking data input by Bob.

The copy will be exclusively owned by Bob in the metadata associated with the copied transmedia content subset or non-linear network, and as such the experience control layer 232 will permit only Bob to edit or modify the copied transmedia content subset or non-linear network. However, the original transmedia content data items and linking data contributed by Alice remain attributed to Alice in the metadata, and only the new transmedia content data items and linking data are attributed to Bob in the metadata. The copied transmedia content subset or non-linear network maintains a reference to the original transmedia content subset or non-linear network.

As Bob interacts with the content by creating, modifying and editing content items, subsets and non-linear networks, it updates in real time such that all other users can see the changes as they happen, including Alice.

In an alternative embodiment, Bob can interact with the content by creating, modifying and editing content items, subsets and non-linear networks so that the changes at this stage can only be seen by Bob. When Bob is finished and no longer wishes to modify the content, subsets or non-linear networks, he can formally submit his changes and the experience control layer 232 provides the copied transmedia content subset or non-linear network to the user, more particularly to the user device of the user that is indicated by the metadata of the original transmedia content subset or non-linear network as the owner, e.g. Alice's user device, for review. Alice may then choose to "merge" the copied transmedia content subset or non-linear network with the original. The experience control layer 232 will delete the original and modify the metadata of the copy to indicate that Alice is owner of the copied transmedia content subset or non-linear network, since Bob will have previously been designated in the metadata as owner of any items, subsets or networks which were created or modified by him. The metadata of the individual transmedia content items and linking data, other than the owner, is left unchanged.

Alice may approve of the modifications made by Bob, but may wish keep the modifications as an optional alternative. In this case, she will choose to "branch" the original transmedia content subset or non-linear network. The experience control layer 232 will modify the original transmedia content subset or non-linear network to include any new transmedia content data items and linking data contributed by Bob. The metadata of the individual transmedia content items and linking data is unchanged, and the metadata for the modified original transmedia content subset or non-linear network still identifies Alice as the owner.

Finally, Alice may disapprove of the modification made by Bob, and can choose to "push out" Bob's version. This causes the experience control layer 232 to remove the reference link from the copy to the original. Again, the metadata of the individual transmedia content items and linking data is unchanged. This means that Bob's version of the content items, subset and non-linear networks as a result of his creation and/or modifications are now distinct from

Alice's, and exists separately in memory with corresponding metadata to indicate that he is the owner of this version.

The system **200** and experience control layer **232** may allow Alice to fully delete Bob's edit, or force the modification to be hidden from other users of the system. Allowing for this option might be required in some cases, for example when copyright is infringed or the content contributed by Bob is inappropriate.

As mentioned above, the system **200** structures groups of content subsets ("storyworlds"), i.e. non-linear networks, as directed graphs of connected transmedia story data items and storylines, i.e. transmedia content subsets, as sequences of connected transmedia content data items out of the generated non-linear networks graphs.

The story model component **236** of the system **200** arranges the stories and storyworlds at the transmedia content level based on complex graph metrics. The transmedia content data items are nodes. Edges of the graph define the time-ordered content links between transmedia content data items. The edges and nodes of the graph may be assigned with weights derived from story attributes, e.g. number of likes received by users consuming the story. The graph-based model defines all of the possible consumption flows throughout a given graph and allows identification of transmedia content data items which play key roles within the storyworld. FIG. 6 depicts a graph-model of two non-linear networks of transmedia content data items.

Each depicted non-linear network, **510** and **520** includes at least two subset entry points **511** and **521** which define starting points in the subset (and also any non-linear networks that the subsets are part of) from which the system should begin presenting the transmedia content data items. Non-linear network **511** has two distinct end points **513**, **516**, which are transmedia content data items that have only incoming time-ordered content links. End point **513** is preceded by a branch **512** of the non-linear network, which shares only its first data item in common with a second brand **514**. Branch **514** has an alternate path **515** which skips several of the transmedia content data items of the rest of the branch and then re-joins the branch **515** to terminate at the end point **516**. In contrast, non-linear network **520** has four branches with four distinct end points **523**, **525**, **526** and **527**, which share varying numbers of transmedia content data items in common with one another. The data thus generated and stored which is representative of the non-linear network is structural data indicative of the nodes and edges and links therebetween, thereby defining the time-ordered structure of content data items in for the non-linear network.

In a hierarchical system containing a lot of changing content at different levels (story systems, non-linear networks, transmedia content subsets and individual transmedia content data items) users can easily get lost in irrelevant content (for the user) or unappealing content (for the user). An engine guiding the user and fostering the creation of high quality content is thus provided.

As mentioned above, the system **200** further includes a recommender engine component **238** in the backend device **230**, which principally provides one or both of two functions namely: (i) surface relevant transmedia content data items, whether as individual items, or as linked content subsets to a given users of the system; and (ii) surface relevant users and their content to the given user. References herein to the "given" user mean a user who is logged into the system **200** via their frontend device **210** and is accessing data, including content items and user data from the backend device **230**.

FIG. 7 shows data flows between some components of the backend device **230**, in particular, the inputs and outputs of the recommender engine component **234** implemented in the backend device **230**.

As mentioned above, the recommender engine component **238** permits users via the frontend device **210** to receive suggestions about possible story elements, i.e. transmedia content data items, to be consumed and/or extended with new content by the given user. Due to the hierarchic nature of the system, recommendations can be issued at one or more different levels of granularity, e.g. story system, non-linear networks, transmedia content subsets and individual transmedia content data items. Furthermore, recommendations are dynamic, i.e. they change with continuously evolving content. Recommendations also take into account preferences of the given user to keep the user engaged with processing the time-arranged content items. This can mean that individual content items from the same or other users with sufficiently similar or identical content characteristic metadata, e.g. specifying content with sufficiently similar characters, occurring at sufficiently similar or identical factual or fictional times, or in sufficiently similar or identical factual or fictional times, as the characteristic metadata of the content which has already been utilised (consumed) by the user can be surfaced by the recommender engine component **238**.

In general terms, the recommender engine component **238** is configured to access the memory **301** of the backend device **230** and surface one or more identifications of individual content items and/or linked transmedia content subsets to a given user of the system. This is achieved with the identifications of such content being passed to experience control layer **232**, as can be seen in FIG. 3 and FIG. 7. In addition, the recommender engine component **238** can be configured to surface users relevant to the given user with one or more identifications of other recommended users being passed to the experience control layer **232**. The experience control layer **232** obtains the received identifications and passes them to frontend device **210** for display in the user interface **218** via the visual navigation component **214**.

The surfaced content items or linked transmedia content subsets are selected by the recommender engine component **238** based on data about the individual transmedia content data items and transmedia content subsets already stored in the memory **301**. In the present context, "surface" means that the selected one or more items of content or users are isolated from other items of content or users and provided as one or more identifications to the given user, e.g. as a notification on the user device, or as a special flag associated with the surfaced item. This way, the given user can readily access the content and/or information and content associated with other users.

The recommender engine component **238** includes a preference model **242**, the function of which is to provide a score of a given transmedia content data item or transmedia content subset for a specific user of the system **200**. The preference model **242** is depicted in FIG. 8.

Referring to FIG. 8, the preference model **242** takes as input, data about one or more transmedia content data items or transmedia content subsets and provides as output to an optimisation component **248** a score for each input item for a given user. The preference model **242** achieves this by, at a first step **601**, removing global effects. Some users might, for example, tend to constantly give lower ratings (user-assigned scores) than others. Removing this bias before processing the input items improves prediction accuracy. In

a second step **602**, the model collects the predictions of n independent state of the art algorithms (such as Rank-based SVD). The system then builds an ensemble prediction at step **603** by using a Lasso Regression. In the last step **604**, the global effects are added back to the ensemble prediction to obtain and output a final suitability score **605** of all input content and users in respect of the given user.

The recommender engine component **238** may also include a user-brand match component **244**, which is configured to provide, for the given user, at least one prediction of a preference for a given branded content data item, and a branded content model **246** that provides, for a given transmedia content data item, a prediction of the suitability of a given branded content data item, e.g. an advertisement.

As shown in FIG. 7, the transmedia content recommender engine **238** additionally implements an optimisation component **248** which is configured to query at least the preference model component **242**, and optionally the user-brand match component **244** and brand model component **246** by providing them with a transmedia content parameter identifying items of content in use and/or a user identification for the given user. The optimisation component **248** acts on the suitability scores it receives to maximise content and/or user recommendations. Reference here to “content in use” generally means the content currently selected and/or being manipulated by the given user in the user interface **218**.

For the case of preference model data only, the optimisation component **248** outputs to the control layer **232** all identifications for recommended content (or linked subsets) and/or users which have a determined suitability score which sufficiently meets a satisfactory threshold particular to the given user or content currently being utilised by the given user. By meeting a particular threshold, this may mean that the suitability score has to be above, or below a particular fixed value, dependant on whether the score is arranged to be ascending or descending respectively in respect of suitability. Alternatively, the optimisation component **248** can rank suitability scores (either for all content or all content which sufficiently meets a threshold) and then output a predetermined number of different content or users identifications down from the top-ranked scores. For example, the optimisation component **248** may output identifications for transmedia content items (or linked content subsets) which been determined in respect of the given user to have the top X highest suitability scores (or lowest depending on whether scores are ascending or descending), as determined by the preference model **242**, where X may be 5, 10, 20, 30, 40, 50 or 100. This one-dimensional optimisation ensures that the given user is engaged by relevant content, particularly in respect of linked content subsets.

In a further embodiment, a three-dimensional optimisation can additionally take into account user-brand matching and brand modelling. In this embodiment, the optimisation component **248** maximises the sum of the output for the preference model component **242**, user-brand match component **244** and brand model component **246** over the transmedia content parameter. This three-dimensional optimisation can ensure that users are both engaged by relevant content, and the content being consumed content which is pertinent a brand relevant to the particular user or existing utilised content.

The recommender engine component **238** may also take into account a given user’s defined preferences, historical behaviour and other predicted properties such as future user behaviour, or inferred properties such as an emotional state. In order to achieve this, the recommender engine component

238 communicates with the user model component **234** depicted in FIG. 3 and shown in more detail in FIG. 9.

FIG. 9 depicts data flows between some components of the backend device **230** in the context of the user model component **234**, in particular, the input and output components of the user model component **234**, many of which are also the input and output components of the recommender engine component **238**. Referring to FIG. 9, the user model component **234**, **234** includes a state model **701**, behaviour model **702**, user profile **703**, interaction model **704** and talent harvest component **705**.

Modelling the state of the user, using state model component **701** permits personalised recommendations to be provided by the recommender engine component **238**, and also provides accurate predictions of user behaviour by the behaviour model component **702**. The state model component **701** may also be used to customise the user interface **218** and encourage users to create new content, i.e. new transmedia content data items and time-ordered content links, within the system **200**. The state model component **701** represents and predicts the continuous creational, emotional and affective state of users of the system **200**. The creational state describes if the user is in the mood for consuming transmedia content subsets or non-linear networks or contributing their own transmedia content data items and time-ordered content links. The affective state indicates whether the user is, for example, motivated or bored. The emotional state describes the emotions that individual transmedia content data items or transmedia content subsets/non-linear networks trigger in the user.

Due to the hierarchy of the system, i.e. the logical separation of transmedia content into levels of the individual transmedia content data items, transmedia content subsets, non-linear networks and story universe, user behaviour is predicted at different levels of granularity in two main dimensions, namely: (1) the transmedia content hierarchy; and (2) the interaction of users with other users. User dynamics are of interest at different levels of user granularity, for example in respect of: single users, small groups, audiences. The behaviour model component **702** predicts the user behaviour in both of these dimensions and provides insights into dynamic behaviour for load balancing, information about the most likely path of a user through a given non-linear network and predicts the evolution of the whole system **200**.

The user preference component **703** provides a detailed profiling for each user of the system **200**, including, for example, demographics (e.g. age, gender, etc.), personality traits (e.g. Big 5) and location data (e.g. GPS).

The interaction model component **704** monitors and predicts social interactions of users. The analysis and prediction of social interactions of groups of contributors can be used by the system **200** to encourage collaboration across all levels of the system, predict the quality of stories and influence user community building.

Talent harvest component **705** identifies users of the system **200** with exceptional talent at creating transmedia content, and categorises these users according to their type of talent, e.g. a Star Wars expert, an artist doing funny comic strips or a user resonating with a specific audience.

As shown in FIG. 9, the user model component **234** is in communication with the story model component **236**, the recommender engine component **238** and the metadata extraction component **240**, with these components being both inputs and outputs to the user model component **234**, allowing data exchange therebetween.

The state model component **701** within the user model predicts or infers the state of a given user from (noisy) observations of the user interacting with the system **200**. The state model component **701** uses a statistical model, such as a hidden Markov model to infer a creational state of the user (i.e. on a scale from creative to consumptive; see FIG. 1), the user's emotional state (e.g. sad, happy, excited, etc.) and the affective state of the user (e.g. engaged with the system **200**, bored, etc.). The state model component **701** further classifies these continuous states into a set of discrete states for further processing (or similar). The observed variables include the profile of the user (e.g. personality), the history of interactions of the user with the system, properties of stories/story elements the user is actually consuming or creating, the environment of the user (e.g. office) and temporal metrics (e.g. working day versus weekends).

The state model component **701** represents user behaviour across different scales/levels of the system (i.e. individual transmedia content data items, transmedia content sub-sets or non-linear networks) by creating a hierarchical, graph-based user model that refines modelled action and states with every level. User behaviour is modelled across different levels of granularity: crowd (e.g. predict behaviour of large numbers of users), community (e.g. defined, sorted groups of users), and at an individual level.

In one embodiment of the invention, the user state and actions are represented by a Hidden Markov Model **900**, depicted in FIG. 11. In this case, the latent variable **901** represents the creational state of the user. The observed variable **902** represents the actions of the user, such as "consuming a transmedia content data item", "rating a transmedia content subset", "creating a new transmedia content data item", etc. The creational state changes dynamically over time and can be inferred from these observed user actions. As a Dynamic Bayesian Network (DBN), this representation can be extended to include the engagement and emotional state of the user as well as the interactions between users.

Navigating through a large quantity of transmedia content data items, transmedia content subsets and non-linear networks that are provided to users by the system **200**, in a way that users and user groups can create and consume the data quickly on a range of devices, including personal computers, laptops, tablets, mobile devices etc. is challenging. The user interface component **218** guides the user in a non-disruptive way, whilst also avoiding repetitive meandering and visual overload of content creation and navigation tools on the multiple, hierarchical levels of the transmedia content.

The user interface component **218** presents the transmedia content data items, transmedia content subsets and non-linear networks as follows. A three-dimensional representation can be utilised based on one or more three-dimensional shapes which can be manipulated by the user. In a two-dimensional system involving a two-dimensional display screen, a two-dimensional representation of the three-dimensional shape(s) is/are generated, and the shape(s) utilised may be one or more spheres or ellipsoids, which use hierarchically-connected visual metaphors to provide further information on the transmedia content data items and how they are related and connected in a time-based manner for users and groups of users. This is achieved in a non-disruptive and non-distracting manner. It will be appreciated that any three-dimensional object may be used to present the transmedia content. In one embodiment of the present invention, the visual metaphors can equate to features of a planet, such as continental landmasses, oceans, clouds, mountain ranges and coastlines.

FIGS. 10A and 10B depict an example of the user interface that is presented to a user of the system **200** at different levels of the hierarchical tree structure. FIG. 10A depicts a higher-level view of the transmedia content **800** which depicts several spheres **801**, **802**. Each sphere **801**, **802** represents a storyworld, i.e. groups of transmedia content subsets and non-linear networks that are semantically similar, e.g. the constituent transmedia content data items relate to the same story characters or story universe. The spheres themselves may be visually clustered together in the displayed three-dimensional representation according to semantic similarity between the storyworlds.

A user may select one of the spheres **801**, **802**, which causes the user interface **800** to transition to a modified user interface **810**, which depicts the selected single sphere **811** with additional detail. Additional surface features of the selected sphere **811** are displayed in user interface **810**, such as individual transmedia content subsets or non-linear networks indicated by icons **813**, and representative images of the content **814**. The visual metaphors are provided such that semantically similar transmedia content subsets and non-linear networks are depicted on the same continents **812** on the surface of the planet **811**. When a user wishes to consume or edit an individual transmedia content subset or non-linear network, the user can select one of the icons **813** or images **814** and the user interface **810** transitions to show a graph-structure of the subset/network and/or the individual transmedia content data items.

FIG. 12 depicts a method for surfacing transmedia content to a given user of the system **200** from the memory **301** of the server device **230**. At step **1201**, the server device **230** receives, e.g. via the network interface, user input indicative of a time-ordering between at least two user-selected transmedia content items. At step **1202**, the processing circuitry **302** of the server device **230** generates, using a transmedia content linking engine, the content linking data for storage in the memory **301** thereby defining a linked transmedia content subset including the at least two user-selected transmedia content items. At step **1203**, the processing circuitry **302** accesses the memory **301** and surfaces transmedia content items, linked transmedia content, identifications of identified users other than the given user and/or the content items associated with at least one identified user other than the given user. The surfaced content items and/or the surfaced linked transmedia content subsets are surfaced for selection by the given user via the transmedia content linking engine as one or more user-selectable transmedia content items.

While some exemplary embodiments of the present disclosure have been shown in the drawings and described herein, it will be appreciated that the methods described herein may be deployed in part or in whole through a computing apparatus that executes computer software, program codes, and/or instructions on processing circuitry, which may be implemented by or on one or more discrete processors. As a result, the claimed electronic device, apparatus and system can be implemented via computer software being executed by the processing circuitry. The present disclosure may be implemented as a method in a system, or on an apparatus or electronic device, as part of or in relation to the apparatus or device, or as a computer program product embodied in a computer readable medium executable on one or more apparatuses or electronic devices.

A processor as disclosed herein may be any kind of computational or processing device capable of executing program instructions, codes, binary instructions and the like. The processor may be or may include a signal processor,

digital processor, embedded processor, microprocessor or any variant such as a co-processor (math co-processor, graphic co-processor, communication co-processor and the like) and the like that may directly or indirectly facilitate execution of program code or program instructions stored thereon. Each processor may be realized as one or more microprocessors, microcontrollers, embedded microcontrollers, programmable digital signal processors or other programmable device, along with internal and/or external memory. A given processor may also, or instead, be embodied as an application specific integrated circuit, a programmable gate array, programmable array logic, or any other device or combination of devices that may be configured to process electronic signals. In addition, each processor may enable execution of multiple programs, threads, and codes. The threads may be executed simultaneously to enhance the performance of the processor and to facilitate simultaneous operations of the application. By way of implementation, the methods, program codes, program instructions and the like described herein may be implemented in one or more thread. The thread may spawn other threads that may have assigned priorities associated with them; the processor may execute these threads based on priority or any other order based on instructions provided in the program code.

Each processor may access one or more memories, for example one or more non-transitory storage media which store the software, executable code, and instructions as described and claimed herein. A storage medium associated with the processor for storing methods, programs, codes, program instructions or other type of instructions capable of being executed by the computing or processing device may include but may not be limited to one or more of a CD-ROM, DVD, memory, hard disk, flash drive, RAM, ROM, cache and the like.

The methods and/or processes disclosed herein, and steps associated therewith, may be realized in hardware, software or a combination of hardware and software suitable for a particular application. The hardware may include a general purpose computer and/or dedicated computing device or specific computing device or particular aspect or component of a specific computing device.

The computer executable code may be created using a structured programming language such as C, an object oriented programming language such as C++, or any other high-level or low-level programming language (including assembly languages, hardware description languages, and database programming languages and technologies) that may be stored, compiled or interpreted to run on one of the above devices, as well as heterogeneous combinations of processors, processor architectures, or combinations of different hardware and software, or any other machine capable of executing program instructions.

Thus, in one aspect, the methods described above and combinations thereof may be embodied in computer executable code that, when executing on one or more computing devices, performs the steps thereof. In another aspect, the methods may be embodied in a system that performs the steps thereof, and may be distributed across electronic devices in a number of ways, or all of the functionality may be integrated into a dedicated, standalone electronic device or other hardware. In another aspect, the means for performing the steps associated with the processes described above may include any of the hardware and/or software described above.

The use of the terms “a” and “an” and “the” and similar referents in the context of describing the disclosure (especially in the context of the following claims) is to be

construed to cover both the singular and the plural, unless otherwise indicated herein or clearly contradicted by context. The terms “comprising”, “having”, “including”, and “containing” are to be construed as open-ended terms (i.e. meaning “including, but not limited to”) unless otherwise noted. Recitation of ranges of values herein are merely intended to serve as a shorthand method of referring individually to each separate value falling within the range, unless otherwise indicated herein, and each separate value is incorporated into the specification as if it were individually recited herein.

The use of any and all examples, or exemplary language (e.g. “such as”) provided herein, is intended merely to better illuminate the disclosure and does not pose a limitation on the scope of the disclosure unless otherwise claimed.

The present disclosure has been provided above by way of example only, and it will be appreciated that modifications of detail can be made within the scope of the claims which define aspects of the invention.

The invention claimed is:

1. An apparatus for surfacing transmedia content to a given user of a plurality of users comprising:

a memory configured to store:

a plurality of transmedia content data items, each content data item being associated with at least one of the plurality of users; and

linking data which define time-ordered content links between the plurality of transmedia content data items, the plurality of transmedia content data items being arranged into linked transmedia content subsets comprising different groups of the transmedia content data items and different content links therebetween, wherein each time-ordered content link defines a directional link from a first transmedia content data item to a second transmedia content data item of the plurality of transmedia content items;

a transmedia content linking engine performed by a processor configured to receive user input indicative of a time-ordering between at least two user-selected transmedia content data items and generate the linking data for storage in the memory, thereby defining a linked transmedia content subset including the at least two user-selected transmedia content data items, wherein the transmedia content linking engine is configured to identify a current user-selected time-ordered location of the given user within a given linked transmedia content subset for insertion of one of the transmedia content data items, and to generate corresponding content linking data therefor upon insertion by the given user of the one or more content data items into the given linked transmedia content subset; and

a recommender engine component, performed by the processor, configured to access the memory and surface to the given user at least one of the following based on the current user-selected time-ordered location: one or more content items of the plurality of transmedia content data items, one or more of the linked transmedia content subsets of the linked transmedia content subsets, one or more identifications of identified users other than the given user, and the content items of the plurality of transmedia content data items associated with at least one identified user other than the given user, wherein the one or more surfaced content data items and/or the one or more surfaced linked transmedia content subsets are surfaced for selection by the

23

given user via the transmedia content linking engine as one or more user-selectable transmedia content data items.

2. The apparatus of claim 1, wherein the memory further includes user ownership data which associates each transmedia content data item to a user of the plurality of users, and each transmedia content subset of multiple content subsets with a user of the plurality of users.

3. The apparatus of claim 1, further comprising a preference model, wherein the preference model is configured to provide a prediction of a rating for a given user for a given transmedia content data item.

4. The apparatus of claim 3, wherein the preference model is configured to:

remove global effects for one or more rated items that have been previously rated by the given user to generate explicit ratings and storing the removed global effects;

provide the explicit ratings and metadata associated with the given transmedia content data item to a plurality of recommender algorithms to generate a plurality of predicted ratings for the given transmedia content data item;

combine the plurality of predicted ratings to build an ensemble prediction of the predicted ratings for the given transmedia content data item;

add the stored global effects to the ensemble prediction to produce a predicted user rating for the given transmedia content data item; and

output the predicted user rating for the given transmedia content data item.

5. The apparatus of claim 3, wherein the apparatus further comprises a user-brand match component configured to provide for a given user a prediction of a preference for a given branded content data item.

6. The apparatus of claim 5, wherein the apparatus further comprises a branded content model configured to provide for a given transmedia content data item a prediction of a suitability of a given branded content data item.

7. The apparatus of claim 6, wherein the recommender engine component is configured to surface transmedia content data items by querying the preference model, user-brand match component and brand model component by providing the preference model, user-brand match component and brand model with a transmedia content parameter, user data for the given user and a given branded content data item, and to maximize a sum of an output for the preference model, user-brand match component and brand model over the transmedia content parameter.

8. The apparatus of claim 7, wherein the recommender engine component is configured to surface a transmedia content data item with a maximum output.

9. The apparatus of claim 1, wherein, the plurality of transmedia content data items comprises items of different content types.

10. The apparatus of claim 1, wherein the transmedia content data items relate to narrative elements of the transmedia content data items.

11. The apparatus of claim 10, wherein the time-ordered content links define a narrative order of the transmedia content data items.

12. The apparatus of claim 1, wherein the first transmedia content data item has a plurality of outgoing time-ordered content links.

13. The apparatus of claim 1, wherein the second transmedia content data item has a plurality of incoming time-ordered content links.

24

14. The apparatus of claim 1, wherein the memory is further configured to store a plurality of subset entry points for the linked transmedia content subsets.

15. The apparatus of claim 14, wherein each subset entry point is a flag indicating a transmedia content data item that has at least one outgoing time-ordered link and no incoming time-ordered links.

16. The apparatus of claim 15, wherein each linked transmedia content subset defines a linear path, wherein a linear path comprises a subset entry point, one or more transmedia content data items and one or more time ordered links between the subset entry point and the transmedia content data items.

17. The apparatus of claim 16, wherein two or more transmedia content subsets share one or more subset entry points, one or more transmedia content data items and/or one or more time ordered content links.

18. The apparatus of claim 17, wherein the recommender engine component is further configured to surface one or more groups transmedia content subsets to the given user, the one or more surfaced groups being surfaced for selection by the given user via the transmedia content linking engine.

19. The apparatus of claim 1, further comprising a user model, wherein the user model is configured to provide a predictions of a mental state and/or a behavior of the given user to the recommender engine.

20. The apparatus of claim 19, wherein the memory is further configured to store a plurality of historical user interaction data items which define the historical interaction of the given user with the apparatus for surfacing transmedia content to the given user of a plurality of users, and wherein the user model is configured to:

receive one or more historical user interaction data items associated with the given user;

provide the one or more historical interaction data items to a statistical model to produce a prediction of a mental state of the given user;

retrieve from the statistical model the predicted mental state of the given user and/or the predicted behavior of the given user; and

output the predicted mental state of the given user and/or the predicted behavior of the given user.

21. The apparatus of claim 20, wherein the statistical model is a hidden Markov model.

22. The apparatus of claim 20, wherein the recommender engine component is further configured to surface one or more individual content items to the given user and/or surface one or more of the linked transmedia content subsets to the given user when the output of the user model indicates the user is in mental state conducive to consuming transmedia content data items.

23. The apparatus of claim 20, wherein the recommender engine component is further configured to surface one or more individual content items to the given user and/or surface one or more of the linked transmedia content subsets to the given user when the output of the user model indicates the predicted behavior of the given user is to consume transmedia content data items.

24. A system for surfacing transmedia content to a given user of a plurality of users comprising:

the apparatus of claim 1;

an electronic device configured to be in communication with the apparatus and receive and display to the given user: the surfaced one or more content items of the plurality of transmedia content items; and/or the surfaced one or more linked transmedia content subsets of the linked transmedia content subsets; and/or the sur-

25

faced one or more identifications of identified users other than the given user; and/or the surfaced content items of the plurality of transmedia content items associated with at least one identified user other than the given user.

25. A method for surfacing transmedia content to a given user of a plurality of users from a memory configured to store a plurality of transmedia content data items, each content item being associated with at least one of the plurality of users, and linking data which define time-ordered content links between the plurality of transmedia content items, the plurality of transmedia content items being arranged into linked transmedia content subsets comprising different groups of the transmedia content items and different content links therebetween, wherein each time-ordered content link defines a directional link from a first transmedia content data item to a second transmedia content data item of the plurality of transmedia content items, the method comprising:

receiving, at a processor, user input indicative of a time-ordering between at least two user-selected transmedia content items, wherein the processor is configured to identify a current user-selected time-ordered location of the given user within a given linked transmedia content subset for insertion of one of the transmedia content data items, and to generate corresponding content linking data therefor upon insertion by the given user of the one or more content data items into the given linked transmedia content subset;

26

generating with the processor the content linking data for storage in the memory, thereby defining a linked transmedia content subset including the at least two user-selected transmedia content items; and

accessing the memory and surfacing to the given user with a recommender engine component, performed by the processor at least one of the following based on the current user-selected time-ordered location: one or more transmedia content items of the plurality of transmedia content data items, one or more of the linked transmedia content subsets of the linked transmedia content subsets, one or more identifications of identified users other than the given user, and the transmedia content items of the plurality of transmedia content data items associated with at least one identified user other than the given user, wherein the one or more surfaced content data items and/or the one or more surfaced linked transmedia content subsets are surfaced for selection by the given user via the transmedia content linking engine as one or more user-selectable transmedia content data items.

26. A non-transitory computer readable medium comprising computer executable instructions, which when executed by a computer, cause the computer to perform the steps of the method of claim **25**.
