(57) **ABSTRACT**

Embodiments of the present disclosure describe mechanisms for radio frequency (RF) ranging between pairs of radio units based on radio signals exchanged between units. An exemplary radio system may include a first radio unit, configured to transmit a first radio signal, and a second radio unit configured to receive the first radio signal, adjust a reference clock signal of the second radio unit based on the first radio signal, and transmit a second radio signal generated based on the adjusted reference clock signal. Such a radio system may further include a processing unit for determining a distance between the first and second radio units based on a phase difference between the first radio signal as transmitted by the first radio unit and the second radio signal as received at the first radio unit. Disclosed mechanisms may enable accurate RF ranging using low-cost, low-power radio units.

**RADIO FREQUENCY RANGING USING
PHASE DIFFERENCE**

TECHNICAL FIELD OF THE DISCLOSURE

The present disclosure generally relates to radio systems and, more particularly, to radio frequency (RF) distance estimation by using phase difference.

BACKGROUND

Radio systems are systems that transmit and receive signals in the form of electromagnetic waves in the RF range of approximately 3 kiloHertz (kHz) to 300 gigaHertz (GHz). Radio systems are commonly used for wireless communications. Two radio units in the same radio system can exchange information wirelessly using protocols such as Bluetooth™, wireless local area network (WLAN) or IEEE 802.15.4 compliant protocols. Some examples of such radio systems include wireless sensor network, Bluetooth enabled handsets, and smart home systems.

In some settings, it may be desirable to be able to determine distance between two radio units automatically (i.e. without or with minimal user intervention), a process referred to as “RF ranging.” For example, pair-wise range measurements between a mobile device and multiple access points with RF ranging can identify the location of the mobile device.

One approach to determining distance between two radio units is to employ phase based measurements, where the differences in phase between signals are analyzed to estimate distance. In such measurements, reference clock signals of the different radio units need to be synchronized to be within tight timing tolerances as specified by a particular application. Such synchronicity may be very difficult to achieve, especially at high clock speeds.

BRIEF DESCRIPTION OF THE DRAWINGS

To provide a more complete understanding of the present disclosure and features and advantages thereof, reference is made to the following description, taken in conjunction with the accompanying figures, wherein like reference numerals represent like parts, in which:

FIG. 1 provides a block diagram illustrating an example radio system according to some embodiments of the present disclosure;

FIG. 2 provides a block diagram illustrating an example radio unit according to some embodiments of the present disclosure;

FIG. 3 presents a flowchart of an example method of operating a radio system to measure a distance between a first and a second radio units based on phase difference, according to some embodiments of the present disclosure;

FIG. 4 provides a block diagram illustrating an arrangement in which the first radio unit transmits a signal to the second radio unit for the purpose of distance measurement using the method shown in FIG. 3, according to some embodiments of the present disclosure;

FIG. 5 provides a block diagram illustrating an arrangement in which the second radio unit transmits a pseudo-reflected signal to the first radio unit for the purpose of distance measurement using the method shown in FIG. 3, according to some embodiments of the present disclosure;

FIG. 6 provides an illustration of various aspects of distance measurement using the method shown in FIG. 3, according to some embodiments of the present disclosure; and

2

FIG. 7 provides a block diagram illustrating an example data processing system that may be configured to implement at least portions of the method shown in FIG. 3, according to some embodiments of the present disclosure.

DESCRIPTION OF EXAMPLE EMBODIMENTS
OF THE DISCLOSURE

Overview

The systems, methods and devices of this disclosure each have several innovative aspects, no single one of which is solely responsible for the all of the desirable attributes disclosed herein. Details of one or more implementations of the subject matter described in this specification are set forth in the description below and the accompanying drawings.

Embodiments of the present disclosure provide mechanisms for RF ranging, namely for determining distances between pairs of radio units, based on radio signals exchanged between them. In particular, disclosed mechanisms use phase difference measurements to determine distances between pairs of different radio units. In one aspect, an exemplary radio system may include a first radio unit, configured to transmit a first radio signal (e.g. first RF signal), and a second radio unit, configured to receive the first radio signal, adjust a reference clock signal of the second radio unit based on the first radio signal, and transmit a second radio signal (e.g. second RF signal) generated based on the adjusted reference clock signal. Such a radio system may further include a data processing unit configured to determine a distance between the first and second radio units based on a phase difference between the first radio signal as transmitted by the first radio unit and the second radio signal, transmitted by the second radio unit, but as received at the first radio unit. Automatically adjusting the reference clock signal of the second radio unit based on the first radio signal may eliminate or at least reduce the burden of requiring synchronicity between reference clocks of the first and second radio units. Disclosed mechanisms may enable accurate RF ranging using low-cost, low-power radio units, and may be particularly suitable to enable existing radio systems, e.g. those used for wireless data communication, to provide distance measurements.

Because the first radio unit is the unit that sends a radio signal used by another, e.g. the second, radio unit to adapt its’ reference clock signal to said radio signal, in the following descriptions, the first radio unit may be referred to as an “anchor” (or as a “master”), while the second radio unit may be referred to as a “tag” (or as a “slave”). In general, the term “radio unit” refers to a unit capable of transmitting and receiving radio signals, e.g. using any of the suitable allocated frequency bands, and may alternatively be referred to as a “TX/RX unit.” In the following, the terms “radio signal” and “RF signal” may be used interchangeably, but, in general, descriptions provided herein may be applicable to signals in the radio spectrum (i.e. the spectrum of electromagnetic radiation other than optical spectrum) other than RF waves, e.g. to microwave signals and/or to terahertz radiations.

As will be appreciated by one skilled in the art, aspects of the present disclosure, in particular aspects of RF ranging using phase difference measurements as described herein, may be embodied in various manners—e.g. as a method, a system, a computer program product, or a computer-readable storage medium. Accordingly, aspects of the present disclosure may take the form of an entirely hardware embodiment, an entirely software embodiment (including firmware, resident software, micro-code, etc.) or an embodi-

ment combining software and hardware aspects that may all generally be referred to herein as a “circuit,” “module” or “system.” Functions described in this disclosure may be implemented as an algorithm executed by one or more hardware processing units, e.g. one or more microprocessors, of one or more computers. In various embodiments, different steps and portions of the steps of each of the methods described herein may be performed by different processing units. Furthermore, aspects of the present disclosure may take the form of a computer program product embodied in one or more computer-readable medium(s), preferably non-transitory, having computer-readable program code embodied, e.g., stored, thereon. In various embodiments, such a computer program may, for example, be downloaded (updated) to the existing devices and systems (e.g. to the existing radio units and/or their controllers, etc.) or be stored upon manufacturing of these devices and systems.

The following detailed description presents various descriptions of specific certain embodiments. However, the innovations described herein can be embodied in a multitude of different ways, for example, as defined and covered by the claims or select examples. In the following description, reference is made to the drawings where like reference numerals can indicate identical or functionally similar elements. It will be understood that elements illustrated in the drawings are not necessarily drawn to scale. Moreover, it will be understood that certain embodiments can include more elements than illustrated in a drawing and/or a subset of the elements illustrated in a drawing. Further, some embodiments can incorporate any suitable combination of features from two or more drawings.

The description may use the phrases “in an embodiment” or “in embodiments,” which may each refer to one or more of the same or different embodiments. Unless otherwise specified, the use of the ordinal adjectives “first,” “second,” and “third,” etc., to describe a common object, merely indicate that different instances of like objects are being referred to, and are not intended to imply that the objects so described must be in a given sequence, either temporally, spatially, in ranking or in any other manner. Various aspects of the illustrative embodiments are described using terms commonly employed by those skilled in the art to convey the substance of their work to others skilled in the art. The terms “substantially,” “approximately,” “about,” etc., may be used to generally refer to being within $\pm 20\%$ of a target value based on the context of a particular value as described herein or as known in the art.

Other features and advantages of the disclosure will be apparent from the following description and the claims.

Example Radio System

FIG. 1 provides a block diagram illustrating an example radio system 100 according to some embodiments of the present disclosure.

As shown in FIG. 1, the system 100 may include at least a first radio unit 110, described to herein as an “anchor” 110, and a first radio unit 120, described herein as a “tag” 120. As described in greater detail below, the anchor 110 may be configured to transmit a first radio signal (e.g. first RF signal), while the tag 120 may be configured to receive the first radio signal, adjust its’ reference clock signal based on the received first radio signal, and transmit a second radio signal (e.g. second RF signal) generated based on the adjusted reference clock signal. In some embodiments, each of the anchor 110 and the tag 120 may be configured to function both as the anchor and the tag as described herein.

As also shown in FIG. 1, the system 100 may further include a data processing unit 130 configured to perform distance determination as described herein. As described in greater detail below, the data processing unit 130 may be configured to determine a distance between the anchor 110 and the tag 120 based on a phase difference between the first radio signal as transmitted by the anchor 110 and the second radio signal, transmitted by the tag 120, as received at the anchor 110.

In some embodiments, the data processing unit 130 may be included within the anchor 110. In other embodiments, the data processing unit 130 may be included external to the anchor 110 and the tag 120, e.g. the data processing unit 130 may be a cloud-based unit, communicatively coupled to one or both of the anchor 110 and the tag 120 and configured to perform distance determination as described herein based on data received from the anchor 110 and, optionally, data received from the tag 120.

In general terms, each of the anchor 110 and the tag 120 can be a device capable of transmitting and receiving radio signals. In some embodiments, each of the anchor 110 and the tag 120 can be a device used to initiate a communication, such as a wireless sensor, a handset, a smart home system device, a computer, a personal digital assistant (PDA), a laptop or electronic notebook, a cellular telephone, an i-Phone™, i-Pad™, a Google Droid™ phone, an IP phone, or any other device, component, element, or object capable of initiating voice, audio, video, media, or data exchanges within the radio system 100. Further exemplary details of how the anchor 110 and the tag 120 may be implemented are shown in FIG. 2.

In some embodiments, one or more of the anchor 110, the tag 120, and the data processing unit 130 may be implemented as a radio access point device that can connect to a wired network using e.g. Bluetooth™, WLAN (e.g. Wi-Fi), IEEE 802.15.4 protocol, 3rd Generation Partnership Project (3GPP) network (e.g. 3G, 4G, Long Term Evolution (LTE), 5G) protocols, non-3GPP network (e.g. WiMAX) protocols, or any other appropriate standard. In some embodiments, one or more of the anchor 110, the tag 120, and the data processing unit 130 may be include software (or reciprocating software) that can coordinate in order to achieve their operations and/or features, as outlined herein. In some embodiments, one or more of these elements may include any suitable algorithms, hardware, software, components, modules, interfaces, or objects that facilitate the operations thereof. This may be inclusive of appropriate algorithms and communication protocols that allow for the effective exchange of data or information.

While the radio system 100 shown in FIG. 1 illustrates only one of each of the anchor 110, the tag 120, and the data processing unit 130, in general, the radio system 100 may include any number of one or more of these elements. In particular, providing more than two radio units such as the anchor 110 and the tag 120 described herein would enable distance determination between various pairs of these units.

Example Radio Unit

FIG. 2 provides a block diagram illustrating an example radio unit 200 according to some embodiments of the present disclosure. In some embodiments, each of the anchor 110 and the tag 120 of the radio system 100 may be implemented as the radio unit 200.

As shown in FIG. 2, the radio unit 200 may include an antenna 202 for transmitting and receiving radio signals, a switch 204 for connecting and disconnecting the antenna 202 to a receive path or a transmit path of the radio unit 200. In general, a receive path of the radio unit 200 may be

considered to include a receive (RX) RF front-end **206**, a digital downconverter **208**, and an I/Q to magnitude/phase converter **210**, while a transmit path of the radio unit **200** may be considered to include a transmit (TX) RF front-end **216**. As also shown in FIG. 2, the radio unit **200** may further include a transmit/receive (TX/RX) voltage controlled oscillator (VCO) **212**, a phase compensation unit **214**, a TX/RX numerically controlled oscillator (NCO) **218**, and a control logic **220**.

While various elements are shown in FIG. 2 as separate units, in various embodiments, two or more of any of those units may be combined. Similarly, in various embodiments, functionality of any of those units may be implemented in further divided units, e.g. the TX/RX VCO **212** may include a separate TX VCO and an RX VCO, or the TX/RX NCO **218** may include a separate TX NCO and an RX NCO. Furthermore, other functional units are not specifically shown in FIG. 2 in order to not clutter the drawing, such as e.g. analog-to-digital converters (ADCs), digital-to-analog converters (DACs), various filters, etc.

Turning to the functionality of the elements shown in FIG. 2, the RX RF front-end **206** may be configured to receive electrical signals **224** indicative of, or representing, wireless radio signals received by the antenna **202**.

The VCO **212** may be configured to generate a local oscillator signal **222** for the receive path and a local oscillator signal **232** for the transmit path. In operation of the radio unit **200**, both the anchor **110** and the tag **120** are configured to step over a plurality of RF frequencies by setting their TX/RX VCOs to generate local oscillator signals **222**, **232** accordingly. Distance determination according to a two-way ranging protocol as described herein and shown in FIG. 3 may then be performed at each of the RF frequencies.

The RX RF front-end **206** may be configured to mix the received radio signals **224** with the local oscillator signal **222** (for the receive path) generated by the TX/RX VCO **212** to generate a downconverted complex intermediate frequency (IF) signals **226**.

The digital downconverter **208** may be configured to perform multiplication operation of the complex IF signal **226** and a complex phase-compensated NCO signal **234** to generate a complex output baseband signal **228**. In particular, in some embodiments, the digital downconverter **208** may be configured to multiply the complex IF signal **226** with a complex conjugate of the complex phase-compensated NCO signal **234**. For example, in one embodiment, the digital downconversion operation performed by the digital downconverter **208** may produce the following output **228**:

$$\text{Output}_I = \text{IF}_I \times \text{NCO}_I + \text{IF}_Q \times \text{NCO}_Q, \text{ and}$$

$$\text{Output}_Q = \text{IF}_Q \times \text{NCO}_I - \text{IF}_I \times \text{NCO}_Q,$$

where Output_I is the in-phase component of the complex output baseband signal **228**, Output_Q is the quadrature component of the complex output baseband signal **228**, IF_I is the in-phase component of the complex IF signal **226**, IF_Q is the quadrature component of the complex IF signal **226**, NCO_I is the in-phase components of the complex phase-compensated NCO signal **234**, and NCO_Q is the quadrature component of the complex phase-compensated NCO signal **234**. As is known in the art, quadrature is a term to describe a complex signal instead of a real signal, with the in-phase and quadrature components corresponding, respectively, to the real and imaginary parts of a complex signal.

The I/Q to magnitude/phase converter **210** may be configured to convert the received Cartesian (I/Q) representa-

tion of the complex output baseband signal (s_{bb}) **228** ($s_{bb} = I + j*Q$) to corresponding magnitude (A) and phase (φ) output (S_{bb}) **230** ($S_{bb} = A \exp(j\varphi)$), indicative of magnitude and phase of the baseband signal **228**. The magnitude/phase output **230** may then be provided to the control logic **220** to enable the control logic to e.g. measure the frequency of the baseband signal **228**.

The TX/RX NCO **218** provides the reference clock signal(s) for the radio unit **200**. In particular, the TX/RX NCO **218** may be configured to generate a TX NCO IF signal **248** for the transmit path (during the frequency offset correction step), which signal may be mixed, by the TX RF front-end **216**, with the TRX VCO signal **232** from the TX/RX VCO **212** to generate the radio signal **236** to be transmitted by the antenna **202**. Thus, the TX RF front-end **216** is configured to generate an upconverted radio signal **236** from the complex IF signal **248** and the TX VCO signal **232**. The TX/RX NCO **218** may also be configured to generate a RX NCO IF signal **238** for the receive path, which may be provided to the phase compensation unit **214** (or directly to the digital downconverter **208**, if the optional phase compensation unit **214** is not implemented).

The phase compensation unit **214** may be configured to compensate for phase shifts in signals processed by the radio unit **200** due to the internal components and paths (e.g. wires) of the radio unit **200**, which compensation may be a part of an optional loopback calibration procedure described herein. To that end, the phase compensation unit **214** may use phase compensation words **242** provided by the control logic **220**. If such a calibration procedure is not implemented, the phase compensation unit **214** may be omitted from the radio unit **200**.

The control logic **220** may be configured to quantify and control adjustment of the frequency and the phase of the reference clock signal of the tag **120**, as described in greater detail below. In particular, the control logic **220** may be configured to adjust frequency and phase of the reference clock signal generated by the TX/RX NCO **218** by computing appropriate adjustments and by indicating those adjustments by sending corresponding frequency and phase offset words **240** to TX/RX NCO **218**. In the embodiments where the phase compensation unit **214** is used, the control logic **220** may further be configured to provide phase compensation words **242** to the phase compensation unit **214** in order to compensate for any internal phase shifts within each radio unit. In various embodiments, at least some functionality of the control logic **220** and the data processing unit **130** may be overlapping, or the functionality described with reference to one may be implemented by the other, and vice versa. Exemplary data processing system which may be used to implement each of the control logic **220** and the data processing unit **130** is shown in FIG. 7.

Further details of the functionality of the radio unit **200** will become apparent from the following descriptions.

Operating a Radio System to Measure a Distance Between Anchor and Tag

FIG. 3 presents a flowchart of an example method **300** of operating a radio system to measure a distance between a first and a second radio units based on phase difference, according to some embodiments of the present disclosure. While the method **300** is described with reference to the radio system **100** described with reference to FIG. 1 where it is assumed that each of the anchor **110** and the tag is implemented as the radio unit **200** described with reference to FIG. 2, in general, the method **300** may be performed by any radio system with anchor and tag being any suitable

radio units, e.g. where at least one of anchor and tag may have at least some, but not necessarily all, of the components of the radio unit **200**.

As described above, during distance measurements, both the anchor **110** and the tag **120** may be configured to step over a plurality of RF frequencies by setting their respective TX/RX VCOs **212**. The anchor **110** and the **120** are then configured to perform a two-way ranging protocol, described herein with reference to steps **306-314** of the method **300**, at each of the RF frequencies.

Thus, as shown in FIG. **3**, the method **300** may begin with step **302** where each of the anchor **110** and the tag **120** sets their TX/RX VCO **212** to a first frequency of the plurality of RF frequencies through which their VCOs **212** are to step as a part of measuring a distance between the anchor **110** and the tag **120**. In some embodiments, the method **300** may begin when both of the anchor **110** and the tag **120** receive some kind of a trigger signal indicating that they are to start distance measurements. In some other embodiments, the anchor **110** and the tag **120** can be configured to negotiate on the measurement start time through data communications, and the method **300** may begin at a negotiated future time. In other embodiments, the method **300** may begin when only the anchor **110** is triggered to start the measurements, and the tag **120** only starts participating in the measurements when it receives the first radio signal from the anchor **110**. In such embodiments, step **302** may be implicitly accomplished by the tag **120** having its TX/RX VCO **212** having set to a certain predefined first frequency.

Optionally, the method **300** may include step **304** during which at least one, but preferably each, of the anchor **110** and the tag **120** perform a loopback calibration procedure to correct for any phase shifts which may be introduced on their receive and transmit paths due to the architecture of these devices. Some loopback calibration procedures are known in the art and any of these known methods may be performed in step **304**. Alternatively, at least one, but preferably each, of the anchor **110** and the tag **120** may be configured to perform a loopback calibration procedure as proposed herein, described in greater detail below.

After that, the anchor **110** and the tag **120** may perform a two-way ranging protocol as described in steps **306-314** for the first frequency of their TX/RX VCOs **212**. In general, the two-way ranging protocol of steps **306-314** may be seen as including three parts: 1) frequency offset correction to adjust the frequency of the reference clock signal of the tag **120**, 2) phase offset correction to adjust the phase of the reference clock signal of the tag **120**, and 3) two-way phase difference measurement based on a radio signal transmitted by the anchor **110** and a radio signal received at the anchor **110** from the tag **120**, the latter signal generated using the adjusted reference clock signal of the tag **120**. During the entirety of the two-way ranging protocol, TX/RX NCOs **218** of both the anchor **110** and the tag **120** may be configured to maintain their oscillation based on the frequency and phase offset control words **240** provided by the control logic **220**, and TX/RX VCOs **232** of both the anchor and tag may be configured to maintain their oscillation based on the setting of their RX RF front-end **206** and/or TX RF front-end **216**.

The frequency offset correction part of the two-way ranging protocol may be viewed as beginning with the step **306** in which the anchor **306** transmits a first wireless radio signal, e.g. a first RF signal. FIG. **4** provides a block diagram illustrating an arrangement **400** in which a first radio unit, e.g. the anchor **110**, transmits a wireless radio signal (schematically illustrated in FIG. **4** as a radio signal **402**) to a second radio unit, e.g. the tag **120**, for the purpose of

distance measurement using the method shown in FIG. **3**, according to some embodiments of the present disclosure. As can be seen in FIG. **4**, the arrangement **400** assumes that each of the anchor **110** and the tag **120** is implemented as the radio unit **200**.

In FIG. **4**, components which are enabled as the anchor **110** transmits the first radio signal to the tag **120** indicated in FIG. **4** are colored with a grey highlight. Thus, FIG. **4** illustrates that, during the frequency offset correction step, the anchor **110** may enable the TX/RX VCO **212** (more specifically, the TX VCO **212**), the TX/RX NCO **218** (more specifically, the TX NCO **218**), the TX RF front-end **216**. As also illustrated in FIG. **4**, at that time, the switch **204** of the anchor **110** is in a position configured to enable a signal path so that the signal **236** may be provided from the TX RF front-end **216** to the antenna **202**, over a suitable wire interconnect (the relevant switch position of the anchor **110** indicated in FIG. **4** with a dotted box **404**). In this manner, the anchor **110** is configured to transmit, e.g. by broadcast, the first wireless radio signal **402** (which may later be received by the tag **120**) as a part of step **306** shown in FIG. **3**. In the illustration of FIG. **4**, the signal **236** is a radio signal provided over the wired connection, which signal is then transmitted wirelessly as the first radio signal **402**. In particular, in step **306**, the TX NCO **218** of the anchor **110** may be configured to generate an IF signal **248**, the TX RF front-end **216** of the anchor **110** may be configured to mix the IF signal **248** with the TX VCO signal **232** to generate the RF signal **236**, and the antenna **202** may then broadcast the RF signal **236** as the wireless first radio signal **402**.

Turning to the tag **120**, as shown in FIG. **4**, during the frequency offset correction part and in the time period when the anchor **110** transmits the first radio signal **402**, the switch **204** of the tag **120** may be in a position configured to enable a signal path so that when the antenna **202** of the tag **120** receives the first radio signal **402** transmitted by the anchor **110**, it may provide a signal **224** representing the received first radio signal **402** to the RX RF front-end **206** of the tag **120** (the relevant switch position of the tag **120** indicated in FIG. **4** with a dotted box **406**). In this manner, the tag **120** is configured to receive the first wireless radio signal **402** transmitted by the anchor **110** in step **306**. The signal **224** is a radio signal provided over the wired connection, which signal is representative of the wireless first radio signal **402** received at the antenna **202** of the tag **120**. As also shown in FIG. **4**, during the frequency offset correction part and in the time period when the anchor **110** transmits the first radio signal **402**, the following components of the tag **120** may be enabled: the TX/RX VCO **212** (more specifically, the RX VCO **212**), the RX RF front-end **206**, the digital downconverter **208**, the I/Q to Mag/Phase converter **210**, the TX/RX NCO **218** (more specifically, the RX NCO **218**), the control logic **220**, and, optionally, the phase compensation unit **214**.

The frequency offset correction part of the two-way ranging protocol may be viewed as further including step **308** in which the tag **120** performs frequency offset correction based on the received first radio signal **402**. In particular, in step **308**, the control logic **220** of the tag **120** may compute how the frequency of the reference clock signal produced by the TX/RX NCO **218** of the tag **120** needs to be adjusted to match the frequency of the received first radio signal **402** and to instruct the TX/RX NCO **218** to perform the necessary adjustment. To that end, during the frequency offset correction step, the antenna **202** of the tag **120** may receive the first wireless radio signal **402**, thus generating the RF signal **224**, then the RX RF front-end **206** of the tag **120** may downconvert the received signal **224** by mixing the

received signal **224** with the RX VCO signal **222** to generate a complex IF signal **226**. The complex IF signal **226** may be provided to the digital downconverter **208** of the tag **120** which may further downconvert the complex IF signal **226** using the complex phase-compensated NCO signal **234**, thus generating a baseband signal **228**. The I/Q to mag/phase conversion unit **210** of the tag **120** may then convert the I/Q complex baseband signal **228** to a corresponding magnitude and phase **230** (which conversion may e.g. be carried out as described above), provided to the control logic **220**. The control logic **220** of the tag **120** may then measure the frequency of the baseband signal **228**, which is indicative of the frequency of the first radio signal **402** transmitted by the anchor **110**, using the phase output **230** from I/Q to Mag/Phase conversion unit **210** of the tag **120**. The control logic **220** of the tag **120** may then correct/adjust the frequency difference between the TX NCO signal **248** of the tag **120** and the IF signal **226** by sending a corrected frequency word **240** to the TX/RX NCO **218** of the tag **120** (i.e. the control logic **220** of the tag **120** may adjust the frequency of the TX NCO signal **248** of the tag **120**). In some embodiments, the control logic **220** of the tag **120** may adjust the frequency of the reference signal **248** produced by the TX NCO **218** to be substantially equal to that of the IF signal **226**. In some embodiments, both TX NCO and RX NCO of the TX/RX NCO **218** of the tag **120** may receive the frequency control word **240** from the control logic **220** and change their oscillation frequency synchronously, thus adjusting the frequency of the reference clock signal of the tag **120** both for RX and TX NCO as a part of step **308**.

Once the frequency of the reference clock signal of the tag **120** has been adjusted, the method **300** may then proceed with step **310** where the tag **120** performs phase offset correction based on the received first radio signal **402** (i.e. step **310** represents the phase correction part of the two-way ranging protocol described herein). During the phase correction part, the anchor **110** may remain in the same state as during the frequency correction part (e.g. as shown in FIG. **4**). During the phase correction step **310**, the tag **120** may be configured to maintain its signal path as during the frequency correction part (e.g. as shown in FIG. **4**), while the control logic **220** of the tag **120** may compute the phase difference between the complex frequency-adjusted RX NCO signal **238**, possibly also phase-compensated for any internal phase shifts during the optional calibration step **304** resulting in the phase-compensated and frequency-adjusted RX NCO signal **234**, and the IF signal **226** using the phase output **230** from the I/Q to Mag/Phase conversion unit **210** of the tag **120**. In other words, if the phase compensation unit **214** is not used, the control logic would use the phase output **230** from the I/Q to Mag/Phase conversion unit **210** of the tag **120** to compute a phase difference between the IF signal **226** and the complex frequency-adjusted RX NCO signal **238**; otherwise, the control logic **220** would compute the phase difference between the IF signal **226** and the phase-compensated and frequency-adjusted RX NCO signal **234**. The control logic **220** may then correct the measured phase difference, namely adjust the phase of the reference clock signal generated by the TX/RX NCO **218** to match (i.e. be substantially equal to or be at a known predefined phase difference to) that of the IF signal **226**, by sending a phase offset word **240** to TX/RX NCO **218** of the tag **120**. In some embodiments, both TX/RX NCO **218** receive the phase offset word **240** and change their instantaneous phase synchronously. In other words, in some embodiments, both TX NCO and RX NCO of the TX/RX NCO **218** of the tag **120** may receive the phase offset word **240** from the control

logic **220** and change their oscillation frequency synchronously, thus adjusting the phase of the reference clock signal of the tag **120** both for RX and TX NCO as a part of step **310**. The control logic **220** may then further determine the magnitude of the first radio signal **402**, as received at the tag **120**, from the magnitude value of the baseband signal **228** provided as the output **230** from the I/Q to Mag/Phase conversion unit **210**. The magnitude of the baseband signal **228** may be substantially proportional to the magnitude of the first radio signal **402** (i.e. of the propagation channel) at the carrier frequency of each frequency step of the VCOs **212**.

The method **300** may then proceed with step **312** in which the tag **120** transmits a second radio signal, e.g. a second RF signal. FIG. **5** provides a block diagram illustrating an arrangement **500** in which the second radio unit, e.g. the tag **120**, transmits a second wireless radio signal (schematically indicated in FIG. **5** as a signal **502**) to the first radio unit, e.g. the anchor **110**, for the purpose of distance measurement using the method shown in FIG. **3**, according to some embodiments of the present disclosure. Similar to FIG. **4**, as can be seen in FIG. **5**, the arrangement **500** assumes that each of the anchor **110** and the tag **120** is implemented as the radio unit **200**, where components which are enabled as the tag **120** transmits the second radio signal **502**, to be received by the anchor **110**, indicated in FIG. **5** by being colored with a grey highlight.

As shown in FIG. **5**, in order to transmit the second radio signal **502** in step **312**, the tag **120** may enable its' TX/RX VCO **212** (more specifically, the TX VCO **212**), the TX/RX NCO **218** (more specifically, the TX NCO **218**), control logic **220**, and TX RF front-end **216**. As also illustrated in FIG. **5**, at that time, the switch **204** of the tag **120** is in a position configured to enable a signal path so that the signal **236** may be provided from the TX RF front-end **216** to the antenna **202**, over a suitable wire interconnect (the relevant switch position of the tag **120** indicated in FIG. **5** with a dotted box **504**). In this manner, the tag **120** is configured to transmit, e.g. by broadcast, the second wireless radio signal **502** (which may later be received by the anchor **110**) as a part of step **312** shown in FIG. **3**. In the illustration of FIG. **5**, the signal **236** is a radio signal provided over the wired connection, which signal is then transmitted wirelessly as the second radio signal **502**). In particular, in step **312**, the TX NCO **218** of the tag **120** may be configured to generate an IF signal **248**, which signal is now frequency- and phase-adjusted as a result of performing steps **308** and **310**, respectively; then the TX RF front-end **216** of the tag **120** may be configured to mix the received IF signal **248** with the TX VCO signal **232** to generate the RF signal **236**, and the antenna **202** of the tag **120** may then broadcast the RF signal **236** as the wireless second radio signal **502**.

Turning to the anchor **110**, in order to be able to receive the wireless second radio signal **502** transmitted by the tag **120**, the anchor **110** may enable the following elements during the time period when the tag **120** transmits the second radio signal **502**: the TX/RX VCO **212** (more specifically, the RX VCO **212**), the RX RF front-end **206**, the digital downconverter **208**, the I/Q to Mag/Phase converter **210**, the TX/RX NCO **218** (more specifically, the RX NCO **218**), the control logic **220**, and, optionally, the phase compensation unit **214**. Furthermore, the switch **204** of the anchor **110** may be in a position configured to enable a signal path so that when the antenna **202** of the anchor **110** receives the second radio signal **502** transmitted by the tag **120**, it may provide a signal **224** representing the received second radio signal **502** to the RX RF front-end **206** of the anchor **110** (the

11

relevant switch position of the anchor 110 indicated in FIG. 5 with a dotted box 506). In this manner, the anchor 110 is configured to receive the second wireless radio signal 502 transmitted by the tag 120 in step 312.

Since the radio signal 502 is generated by the tag 120 using a reference clock signal that was adjusted to have its' frequency and phase to match that of the reference clock signal of the anchor 110, as derived from the first radio signal 402 received from the anchor 110, the radio signal 502 may be seen as a pseudo-reflected RF signal, referring to the reflection of the first radio signal 402 being reflected from the tag 120. Thus, the second radio signal 502 received by the anchor 110 will be substantially coherent (in a time-extended/evolution sense) with the first radio signal 402 broadcasted by the anchor 110, allowing determination of the phase difference between the two in step 314 shown in FIG. 3.

In some embodiments, the anchor 110 may perform the following actions once it receives the second radio signal 502: the RX RF front-end 206 of the anchor 110 may downconvert the signal 224 (indicative of the second radio signal 502 received at the antenna 202 of the anchor 110) by mixing the received signal 224 with the RX VCO signal 220 to generate the complex IF signal 226; the digital downconverter 208 of the anchor 110 then further downconverts the complex IF signal 226 by mixing it with the complex phase-compensated NCO signal 234 if the phase compensation unit 214 is used, or with the complex NCO signal 238 if the phase compensation unit 214 is not used, to generate the complex baseband signal 228; the I/Q to Mag/Phase conversion unit 210 of the anchor 110 then converts the I/Q complex baseband signal 228 to generate corresponding magnitude and phase 230 (where the conversion may be performed e.g. as described above), which magnitude and phase 230 is then provided to the control logic 220 of the anchor 110 (or, in general to any suitable data processing system 130) that can then determine phase difference between the first signal 402 as transmitted by the anchor 110 and the second signal 502 as received by the anchor 110.

Thus, in step 314, the control logic 220 of the anchor 110 (or, in general to any suitable data processing system 130) may determine the magnitude of the second radio signal 502, as received at the anchor 110, from the magnitude value of the baseband signal 228 provided as the output 230 from the I/Q to Mag/Phase conversion unit 210, and determine the phase of the second radio signal 502, as received at the anchor 110, from the phase value of the baseband signal 228 provided as the output 230 from the I/Q to Mag/Phase conversion unit 210. Since the phase of the first radio signal 402 transmitted by the anchor 110 is known, the control logic 220 may then compute the phase difference between the first radio signal 402 as transmitted by the anchor 110 and the second radio signal 502 as received by the anchor 110.

Step 314 may be seen as the two-way phase difference measurement part of the two-way ranging protocol described herein. During the two-way phase difference measurement part, the baseband signal 228 at the anchor 110 may be a DC signal since the tag 120 has corrected the relative frequency difference in step 308; the phase of the baseband signal 228 may be substantially equal to twice of the phase shift caused by the propagation channel at the carrier frequency of each frequency step (as set in steps 302 and 318); the magnitude of the baseband signal 228 may be substantially proportional to the magnitude of the second radio signal 502 (i.e. of the propagation channel) at the carrier frequency of each frequency step of the VCOs 212.

12

As previously described, usually phase difference measurements at different frequencies are performed in order to carry out distance determination based on phase difference. Therefore, the method 300 may then proceed to step 316 where it is determined, e.g. by the control logic 220 of the anchor 110 (or, in general to any suitable data processing system 130) whether more phase difference measurements (and, optionally, first radio signal 402 magnitude measurements, and, further optionally second radio signal 502 magnitude measurements) are needed. If so, then the method 300 proceeds to step 318 where the frequency of the TX/RX VCO 212 of both the anchor 110 and the tag 120 is set to the next value, and the method then proceeds with steps 304-316 as described above but now performed for the next frequency value of the radio signals. This process may be iterated as many times as needed to obtain adequate number of phase difference measurements (and, optionally, first radio signal 402 magnitude measurements, and, further optionally second radio signal 502 magnitude measurements) in order to achieve adequate accuracy for the distance determination. Results of the measurements may be stored in any suitable memory, some examples of which are described with reference to FIG. 7.

Once it is decided, in step 316, that no more phase difference measurements (and, optionally, first radio signal 402 magnitude measurements, and, further optionally, second radio signal 502 magnitude measurements), the method 300 may proceed to step 320 where the distance d between the anchor 110 and the tag 120 may be determined based the measured phase differences performed for the plurality of VCO frequencies, and, optionally, further based on the first radio signal 402 and/or the second radio signal 502 magnitude measurements performed for the plurality of VCO frequencies. In various embodiments, the distance determination of step 320 may be carried out by the control logic 220 of the anchor 110 or by any suitable data processing unit 130.

Any of the techniques known in the art may be used in step 320 to determine the distance between the anchor 110 and the tag 120, e.g. any of the known inverse Fast Fourier Transform (IFFT) or super-resolution algorithm for range estimation. For example, in the case of using super-resolution algorithms or IFFT-based algorithms, the inputs for distance determination algorithm may be presented as vectors of complex numbers, where the phase of the complex numbers is the phase determined in the two-way phase difference measurements described herein. In various embodiments, the magnitude of the complex numbers can be either the magnitude squared of the first radio signal 402 received at the tag 120, or the magnitude squared of the second radio signal 502 received at the anchor 110, or the product of the magnitudes of the first radio signal 402 received at the tag 120 and the second radio signal 502 received at the anchor 110.

Some more details of the method 300 are explained below with reference to FIG. 6, providing an illustration of various aspects of distance measurement using the method shown in FIG. 3, according to some embodiments of the present disclosure. In FIG. 6, timing diagrams 602-614 are illustrated (i.e. the horizontal axis of each of the diagram refers to time), where, for each, different stages of the method 300 are schematically illustrated with vertical dashed lines extending through all of the diagrams. The first vertical dashed line shown in FIG. 6 indicates the end of the part of the method 300 where loopback calibration (step 304) may be performed by each of the anchor 110 and the tag 120. The second vertical dashed line shown in FIG. 6 indicates the

end of the part of the method 300 where frequency offset correction at the tag 120 (step 308) is performed. The third vertical dashed line shown in FIG. 6 indicates the end of the part of the method 300 where phase offset correction at the tag 120 (step 310) is performed. Finally, the last vertical dashed line shown in FIG. 6 indicates the end of the part of the method 300 where phase determination (step 314) is performed.

Diagram 602 illustrates a TX reference signal 248 generated by the TX NCO 218 of the anchor 110 (solid line), and an idealized two-way phase difference signal (dashed line) representing an ideal reflection of the first radio signal 402 transmitted by the anchor 110 from the tag 120. As shown in the diagram 602, an idealized reflection would only have a certain phase shift, shown in FIG. 6 as a phase shift 622, which phase shift is then determined in a step similar to the step 314, and based on which distance between the anchor 110 and the tag 120 may be determined. The goal of the frequency and phase compensation of the reference signal of the tag 120 (i.e. steps 308 and 310) is to make the second radio signal 502, actively generated by the tag 120, appear as if it was a passive reflection of the first radio signal 402 transmitted by the anchor, represented by the dashed line of the diagram 602.

Diagram 604 illustrates a RX reference signal 234 (RX NCO after phase compensation) of the anchor 110 (solid line), and the IF signal 226 (dashed line) at the anchor 110 generated based on the radio signal 224 received at the RX RF front-end 206 of the anchor 110, e.g. based on the received second radio signal 502 transmitted by the tag 120. Thus, following tag phase offset correction, diagram 604 illustrates the actual phase difference 624 as determined in step 314 of the method 300.

Diagram 606 illustrates the phase of the baseband signal 230 determined at the anchor 110, where the portion of the baseband phase 626 (i.e. the portion after the third vertical dashed line and leading up to the fourth vertical dashed line, i.e. after tag performed phase offset correction and transmitted the second radio signal 502 as described herein) is indicative of the phase difference 624 between the first radio signal 402 transmitted by the anchor 110 and the second radio signal 502 transmitted by the tag 120, as received at the anchor 110 (i.e. the phase difference determined in step 314).

Diagram 608 illustrates the RF signal direction during different steps of one two-way phase difference measurement at one carrier frequency (i.e. at a given VCO frequency). As indicated in FIG. 6, the upper portion of the diagram 608 illustrates radio signal directions at the anchor 110, while the lower portion of the diagram 608 illustrates radio signal directions at the tag 120.

Diagram 610 illustrates a TX reference clock signal 248 generated by the TX NCO 218 of the tag 120.

Diagram 612 illustrates a RX reference signal 234 (RX NCO after phase compensation) of the tag 120 (solid line), and the IF signal 226 (dashed line) at the tag 120 generated based on the radio signal 224 received at the RX RF front-end 206 of the tag 120, e.g. based on the received first radio signal 402 transmitted by the anchor 110.

Finally, diagram 614 illustrates the phase of the baseband signal 230 determined at the tag 120.

As shown in the diagram 608, the anchor 110 may begin with performing a loopback calibration (step 304, illustrated with the portion of the diagram 608 before the first vertical dashed line), during which TX RF front-end 216 of the anchor 110 transmits the radio signal 236 directly to the RX RF front-end 216 of the anchor 110 (i.e. the radio signal is looped back to the anchor), by configuring the switch 204

with appropriate switch positions. Thus, the signal 224 received at the RX RF front-end 206 is the same as the transmitted signal 236 except for any phase difference due to the propagation of the signal 236 from the TX RF front-end 216 to the RX RF front-end 206. Diagram 608 illustrates that the tag 120 performs analogous loopback calibration on its end.

During such a calibration step, both the anchor 110 and the tag 120 may be configured to reset the phase compensation control words 242, respectively, so that, within each of the anchor 110 and the tag 120, TX reference signal 248 is substantially identical with the RX reference signal 238. As shown in the diagram 604, before the loopback calibration is complete, the received signal at the anchor 110 (i.e., the IF signal 226 (dashed line) at the anchor 110 generated based on the radio signal 224 received at the RX RF front-end 206 of the anchor 110, which, during loopback calibration, is the transmitted signal 236 transmitted by the TX RF front-end 206 of the anchor 110, with a certain internal phase shift) has a phase shift relative to the RX reference signal 234 (solid line) of the anchor 110. Similarly for the tag 120, as shown in the diagram 612, before the loopback calibration is complete, the received signal at the tag 120 (i.e., the IF signal 226 (dashed line) at the tag 120 generated based on the radio signal 224 received at the RX RF front-end 206 of the tag 120, which, during loopback calibration, is the transmitted signal 236 transmitted by the TX RF front-end 206 of the tag 120, with a certain internal phase shift) has a phase shift relative to the RX reference signal 234 (solid line) of the tag 120.

At the end of the loopback calibration, the baseband phase 230 is measured on both the anchor 110 and tag 120, and the control logic 220 sets the phase compensation control words 242 to realize phase compensation of the step 304. As a result, the received signals at both the anchor 110 and tag 120 are in-phase with the RX reference signals, respectively.

After that, the anchor 110 transmits a wireless radio signal, namely the first radio signal 402 described herein, to the tag 120, as shown in the diagram 608 with a thick arrow from the TX of the anchor 110 to the RX of the tag 120 in the portion between the first and second vertical dashed lines, which allows the tag 120 to correct any frequency offset of its' reference clock signal (step 308). In particular, during the frequency correction step, the anchor generates RF signal 236 based on its TX reference signal 248 (solid line in the diagram 602) and transmits it as the wireless radio signal 402; the tag 120 receives the first wireless signal 402 as the RF signal 224, and downconverts it to the IF signal 226 (dashed line in the diagram 612); the frequency difference between the TX/RX reference signals of the tag 120 and the received IF signal 226 (dashed line in the diagram 612) is determined by the control logic 220 based on the phase output 230 (shown in the diagram 614 of the I/Q to Mag/Phase conversion unit 210) at the tag 120. In some embodiments, the frequency difference may be determined by measuring the slope 634 of the baseband phase output 230 shown in the diagram 614. In other embodiments, the frequency difference may be determined by applying a phase-locked-loop (PLL) configured to lock to the IF signal 226 at the tag 120. At the end of the frequency correction step 308, the control logic 220 of the tag 120 applies the frequency control word 240 to both TX and RX reference clock signals 248, 238 (i.e. solid lines shown in the diagrams 610 and 612, respectively). As a result, the frequency of both TX and RX reference clock signals 248, 238 (i.e. solid lines shown in the diagrams 610 and 612, respectively) is the same as that of the IF signal 226 (dashed line in the diagram

612) at the tag 120 generated based on the received first radio signal 402 transmitted by the anchor 110—this can be seen in the diagrams 610 and 612 between the second and the third vertical dashed lines.

As further seen in the diagram 612 between the second and the third vertical dashed lines, the phase of the reference clock signal (solid line) at the tag 120 is still not the same as that of the received signal (dashed line). Therefore, phase correction step 310 takes place between the second and the third vertical dashed lines shown in FIG. 6. During the phase correction step, after the tag frequency correction is applied, the received IF signal (dashed line in the diagram 612) has substantially the same frequency as the RX reference signal (solid line in the diagram 612) but with an unknown phase offset. The control logic 220 at the tag 120 is then configured to measure the relative phase offset between the received IF signal (dashed line in the diagram 612) and the RX reference signal (solid line in the diagram 612) using the phase output 230 (as shown in the diagram 614) of the I/Q to Mag/Phase conversion 210. At the end of the phase correction step, the control logic 220 of the tag 120 may be configured to apply the phase offset word 240 to both TX and RX reference clock signals (solid lines in the diagrams 610 and 612, respectively) of the tag 120, and may store the magnitude of the received signal in memory. After the phase offset word 240 is applied, the RX reference signal (solid line shown in the diagram 612) at the tag 120 matches the received IF signal (dashed line shown in the diagram 612), and the phase output 230 (as shown in the diagram 614) of the I/Q to Mag/Phase conversion 210 reaches zero.

Finally, during two-way phase difference measurement step shown in FIG. 6 between the third and the fourth vertical dashed lines, the tag 120 generates the RF signal 236, based on its frequency- and phase-adjusted TX reference signal (shown in the diagram 610) and transmits it as the second radio signal 502 to the anchor 110. This is shown in the diagram 608 with a thick arrow from the TX of the tag 120 to the RX of the anchor 110 in the portion between the third and fourth vertical dashed lines. The anchor 110 then receives the signal transmitted by the tag 120, as the RF signal 224, and downconverts it to the IF signal 226 (dashed line in the diagram 604). The control logic 220 of the anchor 110 may then compute the baseband phase (as shown in the diagram 606) as the phase difference between the received IF signal (dashed line in the diagram 604) and the RX reference signal (solid line in the diagram 604) based on the output 230 from the I/Q to Mag/Phase conversion unit 210 at the anchor 110. At the end of the two-way phase difference measurement step, the control logic 220 of the anchor 220 may measure the baseband phase based on the phase output 230 of the I/Q to Mag/Phase conversion unit 210, as described above, and may store the measured phase difference, as well as the magnitude of the received signal in memory.

By implementing the protocol as described above, the measured two-way phase difference 624, i.e. the distance indicated between the horizontal arrows in the diagram 604, should match with twice of the phase change due to the propagation channel, i.e. the distance indicated between the horizontal arrows shown in the diagram 602.

Example Data Processing System

FIG. 7 provides a block diagram illustrating an example data processing system 700 that may be configured to implement at least portions of the method shown in FIG. 3, according to some embodiments of the present disclosure. In some embodiments, each of the data processing unit 130, the

control logic 220 of the anchor 110, and the control logic 220 of the tag 120 may be implemented as the data processing system 700.

As shown in FIG. 7, the data processing system 700 may include at least one processor 702, e.g. a hardware processor 702, coupled to memory elements 704 through a system bus 706. As such, the data processing system may store program code within memory elements 704. Further, the processor 702 may execute the program code accessed from the memory elements 704 via a system bus 706. In one aspect, the data processing system may be implemented as a computer that is suitable for storing and/or executing program code. It should be appreciated, however, that the data processing system 700 may be implemented in the form of any system including a processor and a memory that is capable of performing the functions described within this disclosure.

In some embodiments, the processor 702 can execute software or an algorithm to perform the activities as discussed in this Specification, in particular activities related to distance measurement using two-way phase difference measurements. The processor 702 may include any combination of hardware, software, or firmware providing programmable logic, including by way of non-limiting example a micro-processor, a digital signal processor (DSP), a field-programmable gate array (FPGA), a programmable logic array (PLA), an application specific integrated circuit (ASIC), or a virtual machine processor. The processor 702 may be communicatively coupled to the memory element 704, for example in a direct-memory access (DMA) configuration, so that the processor 702 may read from or write to the memory elements 704.

In general, the memory elements 704 may include any suitable volatile or non-volatile memory technology, including double data rate (DDR) random access memory (RAM), synchronous RAM (SRAM), dynamic RAM (DRAM), flash, read-only memory (ROM), optical media, virtual memory regions, magnetic or tape memory, or any other suitable technology. Unless specified otherwise, any of the memory elements discussed herein should be construed as being encompassed within the broad term “memory.” The information being measured, processed, tracked or sent to or from the anchor 110, the tag 120, the data processing unit 130, any of the components of the radio unit 200, or any of the components of the data processing system 700 could be provided in any database, register, control list, cache, or storage structure, all of which can be referenced at any suitable timeframe. Any such storage options may be included within the broad term “memory” as used herein. Similarly, any of the potential processing elements, modules, and machines described herein should be construed as being encompassed within the broad term “processor.” Each of the elements shown in the present FIGS., e.g. the radio unit 200 and the processor 702, can also include suitable interfaces for receiving, transmitting, and/or otherwise communicating data or information in a network environment.

In certain example implementations, mechanisms for RF ranging using phase difference as outlined herein may be implemented by logic encoded in one or more tangible media, which may be inclusive of non-transitory media, e.g., embedded logic provided in an ASIC, in DSP instructions, software (potentially inclusive of object code and source code) to be executed by a processor, or other similar machine, etc. In some of these instances, memory elements, such as e.g. the memory elements 704 shown in FIG. 7, can store data or information used for the operations described herein. This includes the memory elements being able to

store software, logic, code, or processor instructions that are executed to carry out the activities described herein. A processor can execute any type of instructions associated with the data or information to achieve the operations detailed herein. In one example, the processors, such as e.g. the processor **702** shown in FIG. 7, could transform an element or an article (e.g., data) from one state or thing to another state or thing. In another example, the activities outlined herein may be implemented with fixed logic or programmable logic (e.g., software/computer instructions executed by a processor) and the elements identified herein could be some type of a programmable processor, programmable digital logic (e.g., an FPGA, a DSP, an erasable programmable read-only memory (EPROM), an electrically erasable programmable read-only memory (EEPROM)) or an ASIC that includes digital logic, software, code, electronic instructions, or any suitable combination thereof.

The memory elements **704** may include one or more physical memory devices such as, for example, local memory **708** and one or more bulk storage devices **710**. The local memory may refer to RAM or other non-persistent memory device(s) generally used during actual execution of the program code. A bulk storage device may be implemented as a hard drive or other persistent data storage device. The processing system **700** may also include one or more cache memories (not shown) that provide temporary storage of at least some program code in order to reduce the number of times program code must be retrieved from the bulk storage device **710** during execution. Various measurement data obtained during the two-way RF ranging method described herein may be stored in the memory elements **704**.

As shown in FIG. 7, the memory elements **704** may store an application **718**. In various embodiments, the application **718** may be stored in the local memory **708**, the one or more bulk storage devices **710**, or apart from the local memory and the bulk storage devices. It should be appreciated that the data processing system **700** may further execute an operating system (not shown in FIG. 7) that can facilitate execution of the application **718**. The application **718**, being implemented in the form of executable program code, can be executed by the data processing system **700**, e.g., by the processor **702**. Responsive to executing the application, the data processing system **700** may be configured to perform one or more operations or method steps described herein.

Input/output (I/Q) devices depicted as an input device **712** and an output device **714**, optionally, can be coupled to the data processing system. Examples of input devices may include, but are not limited to, a keyboard, a pointing device such as a mouse, or the like. Examples of output devices may include, but are not limited to, a monitor or a display, speakers, or the like. In some embodiments, the output device **714** may be any type of screen display, such as plasma display, liquid crystal display (LCD), organic light emitting diode (OLED) display, electroluminescent (EL) display, or any other indicator, such as a dial, barometer, or LEDs. The output device **714** may be configured to show the result of the distance measurement performed in accordance with the present disclosure. For example, the output device **714** may be configured to provide a graphical user interface and display graphical representation of the distance measured between one or more pairs of anchors and tags. In some implementations, the system may include a driver (not shown) for the output device **714**. Input and/or output devices **712**, **714** may be coupled to the data processing system either directly or through intervening I/Q controllers.

In an embodiment, the input and the output devices may be implemented as a combined input/output device (illus-

trated in FIG. 7 with a dashed line surrounding the input device **712** and the output device **714**). An example of such a combined device is a touch sensitive display, also sometimes referred to as a “touch screen display” or simply “touch screen”. In such an embodiment, input to the device may be provided by a movement of a physical object, such as e.g. a stylus or a finger of a user, on or near the touch screen display.

A network adapter **716** may also, optionally, be coupled to the data processing system to enable it to become coupled to other systems, computer systems, remote network devices, and/or remote storage devices through intervening private or public networks. The network adapter may comprise a data receiver for receiving data that is transmitted by said systems, devices and/or networks to the data processing system **700**, and a data transmitter for transmitting data from the data processing system **700** to said systems, devices and/or networks. Modems, cable modems, and Ethernet cards are examples of different types of network adapter that may be used with the data processing system **700**.

SELECT EXAMPLES

Example 1 provides a radio system that includes a first radio unit (e.g. the anchor/master described herein), a second radio unit (tag/slave described herein), and a data processing unit (e.g. a hardware processor). The first radio unit is configured to transmit a first radio signal (e.g. first RF signal). The second radio unit is configured to receive the first radio signal, adjust a reference clock signal of the second radio unit based on the first radio signal, and transmit a second radio signal (e.g. second RF signal) generated based on the adjusted reference clock signal. The data processing unit is configured to determine a distance between the first radio unit and the second radio unit based on a phase difference between the first radio signal transmitted by the first radio unit and the second radio signal received at the first radio unit.

Example 2 provides the radio system according to Example 1, where the second radio unit is configured to adjust the reference clock signal of the second radio unit by the second radio unit setting a frequency of the reference clock signal of the second radio unit based on a frequency of the first radio signal received at the second radio unit, and the second radio unit setting a phase of the reference clock signal of the second radio unit based on a phase of the first radio signal received at the second radio unit.

Example 3 provides the radio system according to Example 2, where the second radio unit is configured to set the phase of the reference clock signal of the second radio unit after setting the frequency of the reference clock signal of the second radio unit.

Example 4 provides the radio system according to Examples 2 or 3, where the second radio unit is configured to downconvert the first radio signal to generate a first intermediate frequency (IF) signal, and where setting the frequency of the reference clock signal of the second radio unit based on the frequency of the first radio signal received at the second radio unit includes setting the frequency of the reference clock signal of the second radio unit to be substantially equal to a frequency of the first IF signal generated at the second radio unit.

Example 5 provides the radio system according to Example 4, where setting the phase of the reference clock signal of the second radio unit based on the phase of the first radio signal received at the second radio unit includes setting the phase of the reference clock signal of the second radio

unit to be substantially equal to a phase of the first IF signal generated at the second radio unit.

Example 6 provides the radio system according to any one of the preceding Examples, where the second radio unit includes a NCO configured to generate the reference clock signal as a baseband local oscillator signal.

Example 7 provides the radio system according to any one of the preceding Examples, where the data processing unit is configured to determine the distance further based on a magnitude of the first radio signal received at the second radio unit or/and a magnitude of the second radio signal received at the first radio unit.

Example 8 provides the radio system according to any one of the preceding Examples, where the data processing unit is configured to determine the phase difference and, optionally, the magnitude of the first radio signal received at the second radio unit or/and the magnitude of the second radio signal received at the first radio unit, for each of a plurality of measurements, where, in different measurements, the first radio signal has different frequencies.

Example 9 provides the radio system according to Example 8, where the data processing unit is configured to determine the distance based on the phase difference and, optionally, the magnitude of the first radio signal received at the second radio unit or/and the magnitude of the second radio signal received at the first radio unit, determined for the plurality of measurements.

Example 10 provides the radio system according to Example 1, where the first radio signal has a first frequency, and the first radio unit is further configured to transmit a third radio signal that has a second frequency, different from the first frequency. In this Example, the second radio unit is further configured to receive the third signal, adjust the reference clock signal of the second radio unit based on the third signal, transmit a fourth radio signal generated based on the adjusted reference clock signal, while the data processing unit is configured to determine the distance between the first radio unit and the second radio unit further based on a phase difference between the third signal transmitted by the first radio unit and the fourth signal received at the first radio unit and, optionally, the magnitude of the third radio signal received at the second radio unit or/and the magnitude of the fourth radio signal received at the first radio unit.

Example 11 provides the radio system according to any one of the preceding Examples, where the data processing unit is included in the first radio unit.

Example 12 provides the radio system according to any one of the preceding Examples, where at least one of, but preferably each of, the first radio unit and the second radio unit is configured to perform a calibration, e.g. a loopback calibration, to account for a phase shift within the radio unit.

Example 13 provides the radio system according to any one of the preceding Examples, where the first radio unit and the second radio unit are further configured for wireless data communication.

Example 14 provides a radio unit that includes means (e.g. an antenna) for receiving a first radio signal (e.g. first RF signal) transmitted by a further radio unit; means (e.g. a NCO) for generating a reference clock signal based on which the radio unit is configured to transmit radio signals; means (e.g. a control logic, e.g. implemented as a hardware processor) for adjusting the reference clock signal based on the first radio signal; and means (e.g. an antenna) for transmitting a second radio signal (e.g. second RF signal) generated based on the adjusted reference clock signal, where the second radio signal is configured to enable determination of a distance between the radio unit and the

further radio unit based on a phase difference between the first radio signal transmitted by the further radio unit and the second radio signal transmitted by the radio unit as received at the further radio unit and, optionally, further based on the magnitude of the first radio signal received at the radio unit or/and the magnitude of the second radio signal received at the further radio unit.

Example 15 provides the radio unit according to Example 14, where adjusting the reference clock signal of the radio unit includes adjusting a frequency of the reference clock signal based on a frequency of the first radio signal received at the radio unit, and adjusting a phase of the reference clock signal based on a phase of the first radio signal received at the radio unit.

Example 16 provides the radio unit according to Example 15, where the phase of the reference clock signal is adjusted after adjusting the frequency of the reference clock signal.

Example 17 provides the radio unit according to Examples 15 or 16, further including means (e.g. RX RF front-end) for downconverting the first radio signal to generate a first intermediate frequency (IF) signal, where adjusting the frequency of the reference clock signal of the radio unit based on the frequency of the first radio signal includes adjusting the frequency of the reference clock signal to be substantially equal to a frequency of the first IF signal, and where adjusting the phase of the reference clock signal of the radio unit based on the phase of the first radio signal includes adjusting the phase of the reference clock signal to be substantially equal to a phase of the first IF signal.

Example 18 provides the radio unit according to any one of Examples 14-17, where said first radio signal is one of a plurality of first radio signals, each of the first radio signals having a different frequency, the means for adjusting the reference clock signal based on the first radio signal is configured to adjust the reference clock signal based on the first radio signal for each of the plurality of first radio signals, and the means for transmitting the second radio signal is configured to transmit the second radio signal generated based on the adjusted reference clock signal for each of the plurality of first radio signals.

Example 19 provides the radio unit according to Example 18, where the plurality of first radio signals include radio signals at frequency steps of between about 10 kilohertz and 10 megahertz.

Example 20 provides a non-transitory computer-readable storage medium including instructions for execution which, when executed by a hardware processor, are operable to perform operations including adjusting a reference clock signal of a radio unit based on a first radio signal (e.g. first RF signal) received at the radio unit and transmitted by a further radio unit, where the adjusting includes adjusting a frequency of the reference clock signal based on a frequency of the first radio signal received at the radio unit and adjusting a phase of the reference clock signal based on a phase of the first radio signal received at the radio unit; and generating a second radio signal (e.g. second RF signal) for transmission to the further radio unit, where the second radio signal is generated based on the adjusted reference clock signal and where the second radio signal is configured to enable determination of a distance between the radio unit and the further radio unit based on a phase difference between the first radio signal transmitted by the further radio unit and the second radio signal transmitted by the radio unit as received at the further radio unit and, optionally, further based on the magnitude of the first radio signal received at the radio unit or/and the magnitude of the second radio signal received at the further radio unit.

In further Examples, the non-transitory computer-readable storage medium according to Example 20 may further include instructions operable to perform operations performed by the second radio unit in accordance with any one of Examples 1-13, or/and operations performed by the radio unit in accordance with any one of Examples 14-19.

VARIATIONS AND IMPLEMENTATIONS

While embodiments of the present disclosure were described above with references to exemplary implementations as shown in FIGS. 1-7, a person skilled in the art will realize that the various teachings described above are applicable to a large variety of other implementations. In particular, while some descriptions provided in the present disclosure refer to oscillation sources within the TX/RX VCO 212 as separate oscillation sources (i.e. as RX VCO providing the signal 222 and TX VCO providing the signal 232), these descriptions are applicable to a single source of oscillation to provide both local oscillator signals, 222 and 232. Similarly, while some descriptions provided in the present disclosure refer to oscillation sources within the TX/RX reference clock 218 as separate oscillation sources (i.e. as RX NCO providing the signal 238 and TX NCO providing the signal 248), these descriptions are applicable to a single source of oscillation to provide both reference clock signals, 238 and 248. Further, while some descriptions provided in the present disclosure refer to using the same receive path for loopback calibration and frequency/phase difference measurements, these descriptions are applicable to radio units 200 with a separate receive path for loopback calibration.

In certain contexts, the features discussed herein can be applicable to automotive systems, safety-critical industrial applications, medical systems, scientific instrumentation, wireless and wired communications, radio, radar, industrial process control, audio and video equipment, current sensing, instrumentation (which can be highly precise), and other digital-processing-based systems.

Moreover, certain embodiments discussed above can be provisioned in digital signal processing technologies for medical imaging, patient monitoring, medical instrumentation, and home healthcare. This could include pulmonary monitors, accelerometers, heart rate monitors, pacemakers, etc. Other applications can involve automotive technologies for safety systems (e.g., stability control systems, driver assistance systems, braking systems, infotainment and interior applications of any kind).

In yet other example scenarios, the teachings of the present disclosure can be applicable in the industrial markets that include process control systems that help drive productivity, energy efficiency, and reliability. In consumer applications, the teachings of the signal processing circuits discussed above can be used for image processing, auto focus, and image stabilization (e.g., for digital still cameras, camcorders, etc.). Other consumer applications can include audio and video processors for home theater systems, DVD recorders, and high-definition televisions.

In the discussions of the embodiments above, components of a system, such as e.g. clocks, multiplexers, buffers, and/or other components can readily be replaced, substituted, or otherwise modified in order to accommodate particular circuitry needs. Moreover, it should be noted that the use of complementary electronic devices, hardware, software, etc. offer an equally viable option for implementing the teachings of the present disclosure related to virtual dithering.

Parts of various systems for implementing the RF ranging using phase difference as proposed herein can include electronic circuitry to perform the functions described herein. In some cases, one or more parts of the system can be provided by a processor specially configured for carrying out the functions described herein. For instance, the processor may include one or more application specific components, or may include programmable logic gates which are configured to carry out the functions describe herein. The circuitry can operate in analog domain, digital domain, or in a mixed-signal domain. In some instances, the processor may be configured to carrying out the functions described herein by executing one or more instructions stored on a non-transitory computer-readable storage medium.

In one example embodiment, any number of electrical circuits of the present FIGS. may be implemented on a board of an associated electronic device. The board can be a general circuit board that can hold various components of the internal electronic system of the electronic device and, further, provide connectors for other peripherals. More specifically, the board can provide the electrical connections by which the other components of the system can communicate electrically. Any suitable processors (inclusive of digital signal processors, microprocessors, supporting chipsets, etc.), computer-readable non-transitory memory elements, etc. can be suitably coupled to the board based on particular configuration needs, processing demands, computer designs, etc. Other components such as external storage, additional sensors, controllers for audio/video display, and peripheral devices may be attached to the board as plug-in cards, via cables, or integrated into the board itself. In various embodiments, the functionalities described herein may be implemented in emulation form as software or firmware running within one or more configurable (e.g., programmable) elements arranged in a structure that supports these functions. The software or firmware providing the emulation may be provided on non-transitory computer-readable storage medium comprising instructions to allow a processor to carry out those functionalities.

In another example embodiment, the electrical circuits of the present FIGS. may be implemented as stand-alone modules (e.g., a device with associated components and circuitry configured to perform a specific application or function) or implemented as plug-in modules into application specific hardware of electronic devices. Note that particular embodiments of the present disclosure implementing the RF ranging using phase difference may be readily included in a system on chip (SOC) package, either in part, or in whole. An SOC represents an IC that integrates components of a computer or other electronic system into a single chip. It may contain digital, analog, mixed-signal, and often RF functions: all of which may be provided on a single chip substrate. Other embodiments may include a multi-chip-module (MCM), with a plurality of separate ICs located within a single electronic package and configured to interact closely with each other through the electronic package. In various other embodiments, the RF ranging using phase difference proposed herein may be implemented in one or more silicon cores in ASICs, FPGAs, and other semiconductor chips.

It is also imperative to note that all of the specifications, dimensions, and relationships outlined herein (e.g., the number of processors, logic operations, etc.) have only been offered for purposes of example and teaching only. Such information may be varied considerably without departing from the spirit of the present disclosure, or the scope of the appended claims. The specifications apply only to one

non-limiting example and, accordingly, they should be construed as such. In the foregoing description, example embodiments have been described with reference to particular processor and/or component arrangements. Various modifications and changes may be made to such embodiments without departing from the scope of the appended claims. The description and drawings are, accordingly, to be regarded in an illustrative rather than in a restrictive sense.

Note that with the numerous examples provided herein, interaction may be described in terms of two, three, four, or more electrical components. However, this has been done for purposes of clarity and example only. It should be appreciated that the system can be consolidated in any suitable manner. Along similar design alternatives, any of the illustrated components, modules, and elements of the present FIGS. may be combined in various possible configurations, all of which are clearly within the broad scope of this Specification. In certain cases, it may be easier to describe one or more of the functionalities of a given set of flows by only referencing a limited number of electrical elements. It should be appreciated that the electrical circuits of the present FIGS. and its teachings are readily scalable and can accommodate a large number of components, as well as more complicated/sophisticated arrangements and configurations. Accordingly, the examples provided should not limit the scope or inhibit the broad teachings of the electrical circuits as potentially applied to a myriad of other architectures.

Note that in this Specification, references to various features (e.g., elements, structures, modules, components, steps, operations, characteristics, etc.) included in “one embodiment”, “example embodiment”, “an embodiment”, “another embodiment”, “some embodiments”, “various embodiments”, “other embodiments”, “alternative embodiment”, and the like are intended to mean that any such features are included in one or more embodiments of the present disclosure, but may or may not necessarily be combined in the same embodiments.

It is also important to note that the functions related to the RF ranging using phase difference as proposed herein illustrate only some of the possible functions that may be executed by, or within, system illustrated in the present FIGS. Some of these operations may be deleted or removed where appropriate, or these operations may be modified or changed considerably without departing from the scope of the present disclosure. In addition, the timing of these operations may be altered considerably. The preceding operational flows have been offered for purposes of example and discussion. Substantial flexibility is provided by embodiments described herein in that any suitable arrangements, chronologies, configurations, and timing mechanisms may be provided without departing from the teachings of the present disclosure.

Note that all optional features of the apparatus described above may also be implemented with respect to the method or process described herein and specifics in the examples may be used anywhere in one or more embodiments.

Numerous other changes, substitutions, variations, alterations, and modifications may be ascertained to one skilled in the art and it is intended that the present disclosure encompass all such changes, substitutions, variations, alterations, and modifications as falling within the scope of the appended claims.

Although the claims are presented in single dependency format in the style used before the USPTO, it should be

understood that any claim can depend on and be combined with any preceding claim of the same type unless that is clearly technically infeasible.

The invention claimed is:

1. A radio system, comprising:

a first radio unit, configured to transmit a first radio signal; and

a second radio unit, configured to receive the first radio signal, adjust a reference clock signal of the second radio unit based on the first radio signal, and transmit a second radio signal generated based on the adjusted reference clock signal; and

a data processing unit configured to determine a distance between the first radio unit and the second radio unit based on a phase difference between the first radio signal and the second radio signal received at the first radio unit,

wherein:

the first radio signal has a first frequency,

the first radio unit is further configured to transmit a third radio signal that has a second frequency,

the second radio unit is further configured to receive the third radio signal, adjust the reference clock signal of the second radio unit based on the third radio signal, and transmit a fourth radio signal generated based on the reference clock signal adjusted based on the third radio signal, and

the data processing unit is configured to determine the distance between the first radio unit and the second radio unit further based on a phase difference between the third signal transmitted by the first radio unit and the fourth signal received at the first radio unit.

2. The radio system according to claim 1, wherein the second radio unit is configured to adjust the reference clock signal of the second radio unit based on the first radio signal by:

the second radio unit setting a frequency of the reference clock signal of the second radio unit based on a frequency of the first radio signal received at the second radio unit, and

the second radio unit setting a phase of the reference clock signal of the second radio unit based on a phase of the first radio signal received at the second radio unit.

3. The radio system according to claim 2, wherein the second radio unit is configured to set the phase of the reference clock signal of the second radio unit after setting the frequency of the reference clock signal of the second radio unit.

4. The radio system according to claim 2, wherein the second radio unit is configured to downconvert the first radio signal to generate a first intermediate frequency (IF) signal, and wherein setting the frequency of the reference clock signal of the second radio unit based on the frequency of the first radio signal includes setting the frequency of the reference clock signal of the second radio unit to be substantially equal to a frequency of the first IF signal.

5. The radio system according to claim 4, wherein setting the phase of the reference clock signal of the second radio unit based on the phase of the first radio signal includes setting the phase of the reference clock signal of the second radio unit to be substantially equal to a phase of the first IF signal.

6. The radio system according to claim 1, wherein the second radio unit includes a numerically controlled oscillator configured to generate the reference clock signal as a baseband local oscillator signal.

25

7. The radio system according to claim 1, wherein the data processing unit is configured to determine the distance further based on a magnitude of the first radio signal received at the second radio unit or/and a magnitude of the second radio signal received at the first radio unit.

8. The radio system according to claim 1, wherein: the data processing unit is configured to determine the phase difference for each of a plurality of measurements, where, in different measurements, the first radio signal has different frequencies, and the data processing unit is configured to determine the distance based on the phase difference determined for the plurality of measurements.

9. The radio according to claim 1, wherein the data processing unit is included in the first radio unit.

10. The radio system according to claim 1, wherein: the first radio unit is configured to perform a calibration to account for a phase shift within the first radio unit, or the second radio unit is configured to perform a calibration to account for a phase shift within the second radio unit.

11. A radio unit, comprising:

means for receiving a first radio signal transmitted by a further radio unit;

means for generating a reference clock signal based on which the radio unit is configured to transmit radio signals;

means for adjusting the reference clock signal based on the first radio signal; and

means for transmitting a second radio signal generated based on the adjusted reference clock signal,

wherein:

the second radio signal is configured to enable determination of a distance between the radio unit and the further radio unit based on a phase difference between the first radio signal transmitted by the further radio unit and the second radio signal transmitted by the radio unit as received at the further radio unit,

said first radio signal is one of a plurality of first radio signals, each of the first radio signals having a different frequency,

the means for adjusting the reference clock signal based on the first radio signal is configured to adjust the reference clock signal based on the first radio signal for each of the plurality of first radio signals, and

the means for transmitting the second radio signal is configured to transmit the second radio signal generated based on the adjusted reference clock signal for each of the plurality of first radio signals, and the plurality of first radio signals include radio signals at frequency steps of between 10 kilohertz and 10 megahertz.

12. The radio unit according to claim 11, wherein adjusting the reference clock signal of the radio unit includes:

adjusting a frequency of the reference clock signal based on a frequency of the first radio signal received at the radio unit, and

adjusting a phase of the reference clock signal based on a phase of the first radio signal received at the radio unit.

13. The radio unit according to claim 12, wherein the phase of the reference clock signal is adjusted after adjusting the frequency of the reference clock signal.

14. The radio unit according to claim 12, further comprising:

26

means for downconverting the first radio signal to generate a first intermediate frequency (IF) signal,

wherein adjusting the frequency of the reference clock signal of the radio unit based on the frequency of the first radio signal includes adjusting the frequency of the reference clock signal to be substantially equal to a frequency of the first IF signal, and

wherein adjusting the phase of the reference clock signal of the radio unit based on the phase of the first radio signal includes adjusting the phase of the reference clock signal to be substantially equal to a phase of the first IF signal.

15. The radio unit according to claim 11, wherein each of the radio unit and the further radio unit is one of a wireless sensor, a handset, a smart home system device, or a mobile device.

16. A radio system, comprising:

a first radio unit;

a second radio unit; and

a data processing unit,

wherein the first radio unit is configured to transmit and receive signals at a plurality of different frequencies, and, for each frequency of the plurality of different frequencies:

the first radio unit is configured to transmit a first radio signal at the frequency,

the second radio unit is configured to:

adjust a frequency of the reference clock signal of the second radio unit to be equal to the frequency of the first radio signal,

adjust a phase of the frequency-adjusted reference clock signal of the second radio unit based on a phase of the first radio signal as received by the second unit, and

transmit a second radio signal generated based on the frequency- and phase-adjusted reference clock signal of the second radio unit, and

the data processing unit is configured to determine a phase difference between a phase of the first radio signal as transmitted by the first radio unit and a phase of the second radio signal as received by the first radio unit, and

wherein the data processing unit is configured to determine a distance between the first radio unit and the second radio unit based on the phase difference determined for the each frequency of the plurality of different frequencies.

17. The radio system according to claim 16, wherein each of the first radio unit and the second radio unit is one of a wireless sensor, a handset, a smart home system device, or a mobile device.

18. A radio unit, comprising:

a receiver configured to receive a first radio signal transmitted by a further radio unit;

a data processing unit configured to adjust a reference clock signal of the radio unit based on the first radio signal; and

a transmitter configured to transmit a second radio signal generated based on the reference clock signal adjusted based on the first radio signal,

wherein:

the second radio signal is configured to enable determination of a distance between the radio unit and the further radio unit based on a phase difference between the first radio signal transmitted by the further radio unit and the second radio signal as received at the further radio unit,

27

the first radio signal has a first frequency,
 the receiver is further configured to receive a third radio
 signal transmitted by the further radio unit, the third
 radio signal having a second frequency, different
 from the first frequency,
 the data processing unit is further for adjusting the
 reference clock signal of the radio unit based on the
 third radio signal,
 the transmitter is further for transmitting a fourth radio
 signal generated based on the reference clock signal
 adjusted based on the third radio signal, and
 the fourth radio signal is configured to further enable
 determination of the distance between the radio unit
 and the further radio unit based on a phase difference
 between the third signal transmitted by the further
 radio unit and the fourth signal received at the further
 radio unit.

28

19. The radio unit according to claim **18**, wherein the data
 processing unit is configured to adjust the reference clock
 signal of the radio unit by:

setting a frequency of the reference clock signal of the
 radio unit based on a frequency of the first radio signal
 received at the radio unit, and

setting a phase of the reference clock signal of the radio
 unit based on a phase of the first radio signal received
 at the radio unit.

20. The radio unit according to claim **19**, wherein the data
 processing unit is configured to set the phase of the reference
 clock signal of the radio unit after setting the frequency of
 the reference clock signal of the radio unit.

21. The radio unit according to claim **18**, wherein the
 radio unit is one of a wireless sensor, a handset, a smart
 home system device, or a mobile device.
