CROSS-REFERENCE TO RELATED
APPLICATION

This application is based upon and claims the benefit of priority from Japanese Patent Application No. 2016-020514, filed on Feb. 5, 2016, the entire contents of which is incorporated herein by reference.

TECHNICAL FIELD

The present disclosure relates to a technique for feeding power to an electronic apparatus.

BACKGROUND

Battery-driven devices, such as mobile phone terminals, smart phones, tablet terminals, notebook computers, portable audio players, and the like, incorporate a rechargeable secondary battery and a charging circuit for charging the battery. Some charging circuits charge secondary battery using a DC voltage (bus voltage V_{BUS}) supplied from the outside via a USB cable or a DC voltage from an external AC adapter.

Currently, charging circuits installed in mobile devices are mainly based on a standard called USB Battery Charging Specification (hereinafter referred to as BC standard). There are several types of USB hosts or chargers (hereinafter collectively referred to as USB power feed devices). The BC revision 1.2 standard defines SDP (Standard Downstream Port), DCP (Dedicated Charging Port) and CDP (Charging Downstream Port) as types of USB power feed devices. In addition, a current (current capacity) which can be supplied by a USB power feed device is defined in the BC revision 1.2 standard according to the type of USB device. Specifically, 1500 mA is defined for DCP and CDP and 100 mA, 500 mA and 900 mA are defined for SDP depending on the version of USB.

A standard called USB Power Delivery (hereinafter referred to as PD standard) has been formulated as the next generation secondary battery charging format and system using USB. According to the PD standard, supplyable power increases greatly from 7.5 W of the BC standard to the maximum of 100 W. Specifically, the PD standard allows a supply of voltage (specifically, 12 V or 20 V) higher than 5 V as a USB bus voltage, and thus a supply of charging current (specifically, 2 A, 3 A or 5 A) larger than that in the BC standard is also allowed. The USB PD is also supported in the USB type-C standard.

FIG. 1 is a block diagram of a power feed system 100R studied by the present inventor. This power feed system 100R conforms to the USB type-C standard and includes a power feed device 200R and a power receiving device 300R which are interconnected via a USB cable 102. The power receiving device 300R is mounted on a battery-driven electronic apparatus 400R such as a smart phone, a tablet terminal, a digital camera, a digital video camera, a portable audio player or the like.

The power feed device 200R includes a power supply circuit 202, a PD controller of a power feed side (hereinafter referred to as a power feed side controller) 204, and a receptacle 206. The USB cable 102 is detachably connected

2

to the receptacle 206. There is also a charging adapter in which the USB cable 102 is integrated with the power supply device 200R without the receptacle 206.

The receptacle 206 includes a VBUS terminal for supplying a bus voltage V_{BUS} , a GND terminal for supplying a ground voltage V_{GND} , and a CC (Configuration Channel) terminal. The power supply circuit 202 generates the bus voltage V_{BUS} . The power supply circuit 202 may include an AC/DC converter which receives an AC voltage of 100 V from an external power supply (for example, a commercial AC power supply) (not shown) and converts it to a DC bus voltage V_{BUS} . The bus voltage V_{BUS} generated by the power supply circuit 202 is supplied to the power receiving device 300R via a bus line of the USB cable 102.

The power feed side controller 204 is connected to a PD controller of the power receiving side (hereinafter referred to as a power receiving side controller) 306 via the USB cable 102. The power feed side controller 204 and the power receiving side controller 306 provide a communication function between the power feed device 200R and the power receiving device 300R. In the USB PD standard, the CC terminal is omitted and it is configured to communicate between the power feed device 200R and the power receiving device 300R via a bus line.

The electronic apparatus 400R includes a receptacle 402 and a load 404 in addition to the power receiving device 300R. The load 404 includes a CPU, a memory, a liquid crystal display, an audio circuit and the like. The power feed device 200R is detachably connected to the receptacle 402 via the USB cable 102.

The power receiving device 300R includes a battery 302, a charging circuit 304, the power receiving side controller 306, a microcontroller 308 and a power supply circuit 320. The battery 302 is a rechargeable secondary battery. The charging circuit 304 receives the bus voltage V_{BUS} (also referred to as an adapter voltage V_{ADP} on the side of the power receiving device 300R) from the power feed device 200R via the USB cable 102 and charges the battery 302 with the bus voltage V_{BUS} . The charging circuit 304 is composed of a step-down DC/DC converter, a linear regulator or a combination thereof and, therefore, must satisfy a relationship of $V_{ADP} > V_{BAT}$ in order to charge the battery 302.

A system voltage V_{SYS} corresponding to at least one of the bus voltage V_{BUS} (adapter voltage V_{ADP}) and the voltage V_{BAT} of the battery 302 is supplied from the charging circuit 304 to the power supply circuit 320. The power supply circuit 320 steps up or steps down the system voltage V_{SYS} and supplies a power source voltage V_{DD} to each circuit block of the load 404. The power supply circuit 320 is a multi-channel power supply including a power management IC (Integrated Circuit), a DC/DC converter, a linear regulator and the like.

The power receiving side controller 306 is a port controller related to the USB type-C and communicates (negotiates) with the power feed side controller 204 via the CC line. The microcontroller 308 generally controls functions related to USB charging and power management in the power receiving device 300R.

FIG. 2 is a graphical diagram showing a process of determining the bus voltage V_{BUS} in the USB PD standard of FIG. 1. Here, as an example, it is assumed that the power feed device 200R supports 5 V, 9 V and 12 V. The battery 302 is, for example, a two-cell lithium ion battery and the battery voltage V_{BAT} varies in a range of 6 V to 9 V. In order to charge this battery 302, a bus voltage V_{BUS} of 9 V or higher is required. A priority of the bus voltage V_{BUS} (for

example, 9 V, 12 V, 20V) requested to the power feed device **200R** is defined in the power receiving side controller **306** or the microcontroller **308**.

When the power feed device **200R** is connected to the power receiving device **300R** via the USB cable **102** at time t_0 , an initial bus voltage V_{BUS} of 5 V is supplied to the power receiving device **300R**, thereby establishing a link between the power receiving side controller **306** and the power feed side controller **204** (t_1). The power receiving side controller **306** communicates (negotiates) with the power feed side controller **204** and requests the power feed side controller **204** to provide the bus voltage V_{BUS} of 9 V or higher (t_1 to t_2). In this example, since the power feed device **200R** supports 9 V, the request of the bus voltage $V_{BUS}=9$ V is accepted. Then, after time t_2 , the bus voltage V_{BUS} of 9 V is supplied and a charging operation starts. The battery voltage V_{BAT} rises with the charging operation.

The present inventor has studied the power feed system **100R** of FIG. 1 and has recognized the following problems.

The efficiency of the charging circuit **304** depends on its input voltage V_{ADP} and the battery voltage V_{BAT} (the system voltage V_{SYS}). In the conventional power feed system **100R**, once the bus voltage V_{BUS} is set by negotiation, the set value of the bus voltage V_{BUS} is thereafter fixed. That is, the input voltage of the charging circuit **304** is constant. On the other hand, the battery voltage V_{BAT} varies depending on the SOC (State Of Charge) of the battery **302**. Therefore, in the process of charging (or discharging) the battery **302**, the efficiency of the charging circuit **304** may be significantly lowered depending on the magnitude of the battery voltage V_{BAT} . Reduction in the efficiency of the charging circuit **304** is undesirable from the viewpoint of energy saving and also causes a problem of prolonging the charging time of the battery **302**.

In addition, when the system is operated with the bus voltage V_{BUS} constant, if the power consumption of the power receiving device **300R** exceeds a power which can be supplied by the power feed device **200R**, a situation may occur in which the bus voltage V_{BUS} drops to stop the charging.

The above problems may occur not only in the USB PD standard or the USB type-C standard but also in a power feed system having a similar configuration and protocol.

SUMMARY

The present disclosure provides some embodiments of a power receiving device which is capable of fully utilizing a communication function between a power feed device and the power receiving device.

According to one embodiment of the present disclosure, there is provided a power receiving device which receives power from a power feed device via a removable cable, including: a battery; a charging circuit configured to charge the battery with a bus voltage received from the power feed device via the cable; and a controller configured to communicate with the power feed device and instruct a target value of the bus voltage. The controller adaptively changes the target value of the bus voltage according to a state of the power receiving device.

According to this embodiment, it is possible to adaptively supply a desirable bus voltage to the power receiving device having a state changing from moment to moment.

For example, the state of the power receiving device may include a state of the battery, a state of a load (power consumption/current consumption), a state of the cable, other various electrical or physical states, and the like. The

state of the battery includes a voltage, a current, an SOC (State Of Charge), a temperature and the like of the battery. The state of the load includes a power consumption of the load, a sleep state of the load, and the like.

The controller may change get value of the bus voltage based on at least a voltage of the battery.

The controller may change the target value of the bus voltage so as to increase an efficiency of the charging circuit.

The power receiving device may further include a power supply device configured to receive a system voltage corresponding to at least one of the bus voltage and the voltage of the battery and supply a power source voltage to a load. The controller may change the target value of the bus voltage based on at least a state of the load.

The controller may change the target value of the bus voltage so as to prevent a feed current from the power feed device from running short. Thus, it is possible to prevent the bus voltage from dropping which disables charging the battery.

The charging circuit may include a DC/DC converter. The efficiency of the DC/DC converter depends on both its input voltage, i.e., the bus voltage, and its output voltage, i.e., the battery voltage. Therefore, at least one bus voltage (input voltage) giving the maximum efficiency for a plurality of values of the battery voltage (output voltage) may be obtained in advance.

The charging circuit may include a linear regulator. In this case, the efficiency of the charging circuit can be improved by changing the target value of the bus voltage so that a potential difference between the input and the output of the charging circuit **304** becomes small.

The power receiving device and the power feed device may comply with USB PD (Power Delivery) standard or USB type-C standard.

According to another embodiment of the present disclosure, there is provided an electronic apparatus which includes the above-described power receiving device.

According to another embodiment of the present disclosure, there is provided a controller used in a power receiving device including, in addition to the controller, a battery, a charging circuit which charges the battery with a bus voltage received from a power feed device via a cable, and an internal bus or a signal line which connects at least the power receiving device and the controller. The controller includes: a communication part configured to communicate with the power feed device; and a processor including an interface which communicates with the charging circuit via the internal bus or the signal line and acquires a voltage of the battery. The processor is configured to adaptively change a target value of the bus voltage based on at least the voltage of the battery.

The processor may hold a table defining a correspondence relationship between the voltage of the battery and the target value of the bus voltage.

The correspondence relationship between the voltage of the battery and the target value of the bus voltage may be determined so as to increase an efficiency of the charging circuit.

The power receiving device may further include a power supply device which receives a system voltage corresponding to at least one of the bus voltage and the voltage of the battery and supplies a power source voltage to one or more loads. The controller may receive information indicating a power consumption of the loads from a microcomputer, which is one of the loads, and may change the target value of the bus voltage based on the received information within

5

a range in which a feed power from the power feed device does not fall below the power consumption of the loads.

Any combinations of the above-described elements or changes of the representations of the present disclosure between methods, apparatuses and systems are effective as embodiments of the present disclosure.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram of a power feed system studied by the present inventor.

FIG. 2 is a graphical diagram showing a process of determining a bus voltage V_{BUS} in the USB PD standard of FIG. 1.

FIG. 3 is a block diagram of a power feed system according to an embodiment.

FIG. 4 is a waveform diagram showing adaptive control of a bus voltage V_{BUS} based on a battery voltage V_{BAT} .

FIG. 5 is a view illustrating a configuration example of a controller of a power receiving device.

FIG. 6 is a perspective view of an electronic apparatus including a power feed device.

DETAILED DESCRIPTION

Embodiments of the present disclosure will be now described in detail with reference to the drawings. Like or equivalent components, members, and processes illustrated in each drawing are given like reference numerals and a repeated description thereof will be properly omitted. Further, the embodiments are presented by way of example only, and are not intended to limit the present disclosure, and any feature or combination thereof described in the embodiments may not necessarily be essential to the present disclosure.

In the present disclosure, “a state where a member A is connected to a member B” includes a case where the member A and the member B are physically directly connected or even a case where the member A and the member B are indirectly connected through any other member that does not affect an electrical connection state between the members A and B or does not impair functions and effects achieved by combinations of the members A and B.

Similarly, “a state where a member C is installed between a member A and a member B” includes a case where the member A and the member C or the member B and the member C are indirectly connected through any other member that does not affect an electrical connection state between the members A and C or the members B and C or does not impair function and effects achieved by combinations of the members A and C or the members B and C, in addition to a case where the member A and the member C or the member B and the member C are directly connected.

FIG. 3 is a block diagram of a power feed system **100** according to an embodiment. The power feed system **100** includes a power feed device **200** and a power receiving device **300**.

The power feed device **200** conforms to the USB PD standard and may be a USB host or a USB charger (AC adapter) with or without a host function, or may be a USB charger mounted on a dual-role terminal of a host device. The power receiving device **300** as a power feed destination is connected to a receptacle (also referred to as a USB port or a USB plug) **206** via a USB cable **102**. The power receiving device **300** is typically a USB device but may be a dual-role terminal of a host device or a terminal having a host function.

6

In this embodiment, it is assumed that the power feed system **100** conforms to the USB type-C, and the USB cable **102** is provided with a CC line in addition to a VBUS line and a GND line.

The power feed device **200** has the same configuration as that of FIG. 1. Specifically, a power supply circuit **202** generates a DC bus voltage V_{BUS} to be supplied to the power receiving device **300**. A power feed side controller **204** is connected to a power receiving side controller (hereinafter simply referred to as a controller) **330** via a CC terminal and the USB cable **102**. The power feed side controller **204** and the controller **330** provide a communication function between the power feed device **200** and the power receiving device **300**. In the USB PD standard that supports no USB type-C, the CC terminal is omitted and the power feed side controller **204** and the controller **330** are configured to communicate with each other via a bus line.

Next, the power receiving device **300** will be described. The power receiving device **300** is mounted on an electronic apparatus **400**. The electronic apparatus **400** includes a receptacle **402** and a load **404** in addition to the power receiving device **300**. The load **404** includes a CPU, a memory, a liquid crystal display, an audio circuit, various application processors, a baseband IC and the like. The power feed device **200** is detachably connected to the receptacle **402** via the USB cable **102**.

The power receiving device **300** includes a battery **302**, a charging circuit **304**, a power supply circuit **320** and the controller **330**.

The battery **302** is a rechargeable secondary battery. The charging circuit **304** receives a voltage V_{ADP} corresponding to the bus voltage V_{BUS} from the power feed device **200** via the USB cable **102** and charges the battery **302** with the voltage V_{ADP} . The charging circuit **304** is not particularly limited in its configuration and is composed of a step-down DC/DC converter, a linear regulator or a combination thereof. The charging circuit **304** must satisfy a relationship of $V_{ADP} > V_{BAT}$ in order to charge the battery **302**.

A system voltage V_{SYS} corresponding to at least one of the adapter voltage V_{ADP} and the voltage V_{BAT} of the battery **302** is supplied from the charging circuit **304** to the power supply circuit **320**. The power supply circuit **320** steps up or steps down the system voltage V_{SYS} and supplies a power source voltage V_{DD} to one or more loads **404**. The power supply circuit **320** may be a multi-channel power supply including a plurality of power supplies such as a DC/DC converter, a linear regulator and the like, and a power management IC (Integrated Circuit) for controlling the plurality of power supplies.

The controller **330** integrally controls the power receiving device **300** and has a function of communicating with the power feed side controller **204**. When a link with the power feed side controller **204** is established, the controller **330** negotiates with the power feed side controller **204** to determine the bus voltage V_{BUS} . This point is the same as the above-described conventional power receiving device **300R**. The controller **330** may be a single IC or module or may include a plurality of ICs.

In this embodiment, the controller **330** further adaptively changes a target value bus voltage V_{BUS} according to the state of the power receiving device **300** even during the charging of the battery **302**, and transmits data **S3** indicating the target value to the power feed device **200**.

The state of the power receiving device **300** which is referred to by the controller **330** in controlling the bus voltage V_{BUS} may include a state **S1** of the battery **302** and a state of input power or output power, in other words, a state

S2 of the load **404**. The state S1 of the battery **302** includes a voltage V_{BAT} , a current (charging/discharging current) I_{BAT} , an SOC (State Of Charge), that is, a residual capacity, a temperature and the like of the battery **302**. The state S2 of the load **404** includes a power consumption of the load **404**, a sleep state of the load **404**, and the like.

The power receiving device **300** can monitor its own ever-changing state. Therefore, by predefining a desirable level of the bus voltage V_{BUS} corresponding to the state of the power receiving device **300**, it is possible to adaptively supply the desirable bus voltage V_{BUS} to the power receiving device **300**.

Next, the control of the bus voltage V_{BUS} by the controller **330** will be described in detail.

(1) First Control

The above-described adaptive control of the bus voltage V_{BUS} can be used to improve the efficiency of the charging circuit **304**, for example. That is, the controller **330** may change the target value of the bus voltage V_{BUS} so as to increase the efficiency of the charging circuit **304**.

As described above, the charging circuit **304** is composed of a DC/DC converter or a linear regulator. The efficiency of the DC/DC converter and the linear regulator depends on its input voltage, that is, the bus voltage V_{BUS} , and its output voltage, that is, the battery voltage V_{BAT} (V_{SYS}). Therefore, the controller **330** obtains at least one bus voltage (input voltage) V_{BUS} that gives the maximum efficiency (or the equivalent efficiency thereof) for a plurality of values of the battery voltage (output voltage) V_{BAT} beforehand and holds the bus voltage V_{BUS} in a processor. Then, the controller **330** may change the target value of the bus voltage V_{BUS} based on at least the voltage V_{BAT} of the battery **302**.

In a case where the bus voltage V_{BUS} giving the maximum efficiency of the charging circuit **304** depends not only on the battery voltage V_{BAT} but also on the temperature and the charging/discharging current, the controller **330** can take into consideration the temperature and the current in addition to the battery voltage V_{BAT} .

FIG. 4 is a waveform diagram showing the adaptive control of the bus voltage V_{BUS} based on the battery voltage V_{BAT} . The number of cells and conditions of the battery are the same as in FIG. 2. The operation from time t_0 to time t_2 is the same as the conventional one in FIG. 2. At time t_2 , the target value of the bus voltage V_{BUS} once becomes 9 V determined by negotiation. Thereafter, the controller **330** determines the bus voltage V_{BUS} which provides the maximum efficiency, based on the battery voltage V_{BAT} and instructs the power feed device **200** via the CC line. In response to this instruction, the power supply circuit **202** raises the bus voltage V_{BUS} . During the progress of charging, as the battery voltage V_{BAT} rises and the bus voltage V_{BUS} giving the maximum efficiency changes, the controller **330** changes the target value of the bus voltage V_{BUS} and reports the target value to the power feed device **200** (t_4). This operation is repeated (t_4 , t_5 , ...) so that the target value of the bus voltage V_{BUS} is adaptively controlled. According to the first control, the charging circuit **304** can be operated with high efficiency.

(Second Control)

The adaptive control of the bus voltage V_{BUS} may be performed in consideration of a relation with the current supply capability of the power feed device **200**. When the electronic apparatus **400** requests a predetermined amount of power, an input current (supply current from the power feed device **200**) is inversely proportional to an input voltage (bus voltage). If the target value of the bus voltage V_{BUS} is changed in consideration of only the efficiency of the

charging circuit **304**, there is a possibility that the current supply capability of the power feed device **200** becomes insufficient and the power required by the load **404** cannot be obtained. Therefore, the controller **330** may change the target value of the bus voltage V_{BUS} so that the supply current from the power feed device **200** does not run short. Thus, it is possible to prevent the bus voltage V_{BUS} from being dropped to make the charging impossible due to the insufficient current capability of the power feed device **200**.

In this case, the controller **330** needs to estimate the power consumption of the load **404**. A system controller **406** (see FIG. 3), which is one of the loads **404**, integrally controls the entire electronic apparatus **400**. Therefore, the system controller **406** grasps the operation state of the other circuit blocks, so that it is possible to estimate the power consumption of the load **404** with high accuracy or roughly. The controller **330** may receive information S2 indicating the power consumption (that is, an output power P_{OUT} of the power receiving device **300**) from the system controller **406** and reflect the information S2 in the control of the target value of the bus voltage V_{BUS} . Alternatively, the current supplied from the charging circuit **304** to the power supply circuit **320** may be monitored and the power consumption may be estimated based on this current.

In addition, the input power of the electronic apparatus **400** also includes a charging power to the battery **302**. Therefore, the controller **330** may reflect the charge current I_{BAT} of the battery **302** in the target value of the bus voltage V_{BUS} .

(Third Control)

The adaptive control of the bus voltage V_{BUS} may be performed in consideration of a power loss of the cable **102**. For example, a poor USB cable **102** may include a bus line having a significantly large resistance. Flowing a large amount of current through such a cable increases a loss, and may result in a shortage of the adapter voltage V_{ADP} due to a voltage drop, an increase in heat generation in the USB cable **102**, and the like, which are undesirable. Therefore, when the loss of the USB cable **102** is large, the power receiving device **300** may increase the target value of the bus voltage V_{BUS} to reduce the amount of current flowing through the cable. The resistance of the USB cable **102** can be estimated from a difference between the target value of the bus voltage V_{BUS} generated by the controller **330** and an actually supplied adapter voltage V_{ADP} .

The several controls described above may be used alone or in proper combination.

Note that, even though the function of finely setting the bus voltage between 5 V, 9 V, 12 V and 20 V is implemented in the USB PD standard and the USB type-C standard, the above function of the power receiving device **300** according to the embodiment should not be confused with the conventional one. Conventionally, when the bus voltage V_{BUS} is set to 5.2 V by an adjustment function, the set value is fixed even if the state of the power receiving device **300** changes, which is different from the present disclosure.

FIG. 5 is a view illustrating a configuration example of the controller **330** of the power receiving device **300**. For example, the controller **330** includes a communication part **332** and a processor **334**. The communication part **332** may be a port controller which implements a physical layer of the USB type-C and communicates with the power feed side controller **204** via the CC line. The processor **334** may be a microcontroller that integrally controls the power receiving device **300**. The communication part **332** and the processor **334** may be configured as separate hardware or may be

configured as a single chip. The configuration of the controller 330 is not particularly limited.

For example, the charging circuit 304 includes a charging control IC 342 or a fuel gauge IC. The processor 334 includes an interface 340 which is connected to the charging control IC 342 via an internal bus 336 and reads the information S1 indicating the voltage of the battery 302. The processor 334 may set the target value of the bus voltage V_{BUS} based on the battery voltage V_{BAT} read from the charging circuit 304. The internal bus 336 may be an I²C (Inter IC) bus or an SPI (Serial Peripheral Interface). Alternatively, the internal bus may be replaced with a signal line such as GPIO (General Purpose Input/Output). Similarly, the processor 334 and the system controller 406 are connected via an internal bus 338 or a signal line. The system controller 406 may be connected to the internal bus 336.

Alternatively, if the processor 334 contains an A/D converter, the battery voltage V_{BAT} may be input to this A/D converter to allow the processor 334 to directly acquire the battery voltage V_{BAT} .

Incidentally, the processor 334 may include a table defining a relationship between the target value of the bus voltage V_{BUS} and the battery voltage V_{BAT} and the target value may be determined by referring to the table. Alternatively, an arithmetic formula indicating the relationship may be defined and the processor 334 may calculate the target value based on the arithmetic formula.

The present disclosure has been described above by way of embodiments. The disclosed embodiments are illustrated only. It should be understood by those skilled in the art that various modifications to combinations of elements or processes may be made and such modifications fall within the scope of the present disclosure. Such modifications will be described below.

In the embodiment, the USB PD standard or the USB type-C standard is taken as an example, but the present disclosure is not limited thereto. For example, the present disclosure can also be used in the next generation USB standards and their derivatives to be developed in the future, and independent standards such as QuickCharge 2.0. (Applications)

Finally, applications of the power receiving device 300 will be described. FIG. 6 is a perspective view of an electronic apparatus 500 including a power feed device 200. The electronic apparatus 500 as an example is a smart phone or a tablet terminal. The electronic apparatus 500 includes the above-described power receiving device 300 in addition to a receptacle 502, a housing 504, a display panel 506, a CPU 510 and a baseband IC 512. The power receiving device 300 supplies a power source voltage to loads such as the CPU 510 and the baseband IC 512 while charging the battery 302. The electronic apparatus 500 may be a notebook PC, a digital camera, a digital video camera, an audio player or the like.

According to the present disclosure in some embodiments, it is possible to provide a power receiving device which is capable of fully utilizing a communication function between a power feed device and the power receiving device, while solving problems which may occur in conventional power feed systems.

While certain embodiments have been described, these embodiments have been presented by way of example only, and are not intended to limit the scope of the disclosures. Indeed, the novel methods and apparatuses described herein may be embodied in a variety of other forms; furthermore, various omissions, substitutions and changes in the form of the embodiments described herein may be made without

departing from the spirit of the disclosures. The accompanying claims and their equivalents are intended to cover such forms or modifications as would fall within the scope and spirit of the disclosures.

What is claimed is:

1. A power receiving device which receives power from a power feed device via a removable cable, comprising:
 - a battery;
 - a charging circuit configured to charge the battery with a bus voltage received from the power feed device via the cable;
 - a controller configured to communicate with the power feed device and instruct a target value of the bus voltage; and
 - an internal bus or a signal line which connects at least the power receiving device and the controller,
 wherein the controller comprises:
 - a communication part configured to communicate with the power feed device; and
 - a processor including an interface which communicates with the charging circuit via the internal bus or the signal line to acquire a voltage of the battery, and communicates with the communication part via the internal bus or the signal line to instruct the power feed device, and
 wherein the processor is configured to:
 - determine the target value of the bus voltage based on at least the voltage of the battery;
 - instruct the power feed device such that the bus voltage becomes the target value to charge the battery; and
 - instruct, after the bus voltage becomes the target value, the power feed device to adaptively change the target value based on the voltage of the battery during a progress of charging the battery.
2. The power receiving device of claim 1, wherein the controller changes the target value of the bus voltage based on at least the voltage of the battery.
3. The power receiving device of claim 1, wherein the controller changes the target value of the bus voltage so as to increase an efficiency of the charging circuit.
4. The power receiving device of claim 1, further comprising:
 - a power supply device configured to receive a system voltage corresponding to at least one of the bus voltage and a voltage of the battery and supply a power source voltage to a load,
 wherein the controller changes the target value of the bus voltage based on at least a state of the load.
5. The power receiving device of claim 4, wherein the controller changes the target value of the bus voltage so as to prevent a feed current from the power feed device from running short.
6. The power receiving device of claim 1, wherein the charging circuit includes a DC/DC converter.
7. The power receiving device of claim 1, wherein the charging circuit includes a linear regulator.
8. The power receiving device of claim 1, wherein the power receiving device and the power feed device comply with USB PD (Power Delivery) standard or USB type-C standard.
9. An electronic apparatus comprising a power receiving device of claim 1.
10. A controller used in a power receiving device including, in addition to the controller, a battery, a charging circuit which charges the battery with a bus voltage received from a power feed device via a cable, and an internal bus or a

11

signal line which connects at least the power receiving device and the controller, the controller comprising:

a communication part configured to communicate with the power feed device; and

a processor including an interface which communicates with the charging circuit via the internal bus or the signal line to acquire a voltage of the battery, and communicates with the communication part via the internal bus or the signal line to instruct the power feed device,

wherein the processor is configured to:

determine a target value of the bus voltage based on at least the voltage of the battery;

instruct the power feed device such that the bus voltage becomes the target value to charge the battery; and

instruct, after the bus voltage becomes the target value, the power feed device to adaptively change the target value based on the voltage of the battery during a progress of charging the battery.

11. The controller of claim **10**, wherein the processor holds a table defining a correspondence relationship between the voltage of the battery and the target value of the bus voltage.

12

12. The controller of claim **11**, wherein the correspondence relationship between the voltage of the battery and the target value of the bus volt is determined so as to increase an efficiency of the charging circuit.

13. The controller of claim **10**, wherein the power receiving device further includes:

a power supply device which receives a system voltage corresponding to at least one of the bus voltage and the voltage of the battery and supplies a power source voltage to one or more loads, and

wherein the controller receives information indicating a power consumption of the loads from a microcomputer, which is one of the loads, and changes the target value of the bus voltage based on the received information so as to prevent a feed current from the power feed device from running short.

14. The controller of claim **10**, wherein the controller is integrated on a single semiconductor substrate.

15. The controller of claim **10**, wherein the processor is configured to adjust an amount of current flowing through the cable based on a difference between the target value of the bus voltage and the bus voltage received from the power feed device.
