**ABSTRACT**

An aberration engine that collects data sensed by a monitoring system that monitors a property of a user and aggregates the collected data over a period of a time. The aberration engine detects, within the aggregated data, patterns of recurring events and, based on detecting the patterns of recurring events within the aggregated data, takes action related to the monitoring system based on the detected patterns of recurring events within the aggregated data.

No. 9,165,455, issued Oct. 20, 2015, which is a continuation of U.S. application Ser. No. 13/608,148, filed Sep. 10, 2012, now U.S. Pat. No. 8,786,425, issued Jul. 22, 2014, which claims the benefit of U.S. Provisional Application No. 61/532,603, filed Sep. 9, 2011, each of which is incorporated herein by reference in its entirety for all purposes.

**TECHNICAL FIELD**

This disclosure relates to monitoring technology and, for example, detecting events based on a pattern of past monitoring activity.

**BACKGROUND**

Many people equip homes and businesses with alarm systems to provide increased security for their homes and businesses. Alarm systems may include control panels that a person may use to control operation of the alarm system and sensors that monitor for security breaches. In response to an alarm system detecting a security breach, the alarm system may generate an audible alert and, if the alarm system is monitored by a monitoring service, the alarm system may send electronic data to the monitoring service to alert the monitoring service of the security breach.

**SUMMARY**

Techniques are described for monitoring technology. For example, techniques are described for detecting events based on a pattern of past monitoring activity.

Implementations of the described techniques may include hardware, a method or process implemented at least partially in hardware, or a computer-readable storage medium encoded with executable instructions that, when executed by a processor, perform operations.

The details of one or more implementations are set forth in the accompanying drawings and the description below. Other features will be apparent from the description and drawings, and from the claims.

**DESCRIPTION OF DRAWINGS**

FIGS. 1A-1C illustrate examples of using patterns of recurring events to control monitoring system operations.

FIG. 2 illustrates an example system.

FIGS. 3, 8, 10, and 12 are flow charts of example processes.

FIGS. 4 and 9 illustrate example data records.

FIGS. 5-7, 11, 13, and 14 illustrate example interfaces.

**DETAILED DESCRIPTION**

Techniques are described for detecting abnormal activity in a property monitored by a monitoring (e.g., security)

system even when the monitoring (e.g., security) system has not been armed by a user. For instance, an aberration engine monitors events detected by a security system and attempts to detect abnormal activity even when the security system is unarmored. Each event will get an “abnormality score” (more than just true/false), and a bunch of slightly suspicious events in a short period of time will aggregate to cause the engine to alert the user. In this regard, the security system may be helpful in monitoring the property even when the user forgets to arm the security system and the security system otherwise would not detect an alarm event.

FIGS. 1A-1C illustrate examples of using patterns of recurring events to control monitoring system operations. As shown in FIG. 1A, a property 10 (e.g., a home) of a user 50 is monitored by an in-home monitoring system (e.g., in-home security system) that includes components that are fixed within the property 10. The in-home monitoring system includes a control panel 20, a front door sensor 22, a motion sensor 24, and a back door sensor 26. The front door sensor 22 is a contact sensor positioned at a front door of the property 10 and configured to sense whether the front door is in an open position or a closed position. The motion sensor 24 is configured to sense a moving object within the property 10. The back door sensor 26 is a contact sensor positioned at a back door of the property 10 and configured to sense whether the back door is in an open position or a closed position.

The control panel 20 communicates over a short-range wired or wireless connection with each of the front door sensor 22, the motion sensor 24, and the back door sensor 26 to receive sensor data descriptive of events detected by the front door sensor 22, the motion sensor 24, and the back door sensor 26. The control panel 20 also communicates over a long-range wired or wireless connection with a monitoring server 30. The monitoring server 30 is located remote from the property 10 and manages the in-home monitoring system at the property 10, as well as other (and, perhaps, many more) in-home monitoring systems located at different properties that are owned by different users. The monitoring server 30 receives, from the control panel 20, sensor data descriptive of events detected by the sensors included in the in-home monitoring system of the property 10.

In the example shown in FIG. 1A, the monitoring server 30 collects and aggregates sensor data received from the control panel 20 over a period of time. The period of time may be relatively long and may include sensor data collected over the course of several days, several weeks, several months, and even several years. And, the aggregated sensor data may include all events sensed by the in-home monitoring system during the period of time, regardless of whether the in-home monitoring system was armed in a manner in which the in-home monitoring system detects alarm conditions when the events occurred. The monitoring server 30 analyzes the aggregated sensor data with other data available to the monitoring server 30, such as location data for the user 50, and, based on the analysis, detects patterns of recurring events within the aggregated sensor data and the other data available to the monitoring server 30. The recurring events may be positive events tied to activity in the property detected by the in-home monitoring system or may be negative events that reflect a lack of activity (or a lack of a particular type of activity) in the property detected by the in-home monitoring system.

After detecting patterns of recurring events within the aggregated sensor data and the other data available to the monitoring server 30, the monitoring server 30 stores the

detected patterns **40** in electronic storage accessible to the monitoring server **30**. As shown in the detected patterns **40**, the monitoring server **30** has detected a pattern that, on Monday to Thursday between eight in the morning and five in the afternoon, no door activity exists and a location of the user **50** is away from the property **10**. The monitoring server **30** also has detected a pattern that a back door open event detected by the back door sensor **26** is typically (e.g., always) preceded by an interior motion detection by the motion sensor **24**. The monitoring server **30** further has detected a pattern that, on Monday to Thursday between five and six in the afternoon, the front door sensor **22** detects opening of the front door and a location of the user **50** at the property **10**.

The monitoring server **30** uses the detected patterns **40** to perform operations related to the in-home monitoring system without requiring input from the user **50** to define rules for the detected patterns. For example, in the example shown in FIG. 1A, the control panel **20** detects a front door open event on a Tuesday at 11 AM based on output from the front door sensor **22**. In this example, the control panel **20** does not detect an alarm condition based on the front door open event because the in-home monitoring system is in an unarmed state (e.g., the user **50** forgot to arm the in-home monitoring system upon leaving). The control panel **20** sends a message to the monitoring server **30** indicating detection of the front door open event on Tuesday at 11 AM at a time when the in-home monitoring system is in an unarmed state. The monitoring server **30** receives the message from the control panel **20** and compares the front door open event on Tuesday at 11 AM with the detected patterns **40** that were automatically identified by the monitoring server **30** based on past sensor and other activity collected by the monitoring server **30**. Based on the comparison, the monitoring server **30** determines that the front door open event on Tuesday at 11 AM conflicts with the first detected pattern of no door activity on Monday to Thursday between eight in the morning and five in the afternoon.

To confirm whether the first detected pattern is violated, the monitoring server **30** determines a location of the user **50** based on a location of the user's mobile phone **60**. The monitoring server **30** may determine the location of the user's mobile phone **60** based on Global Positioning System (GPS) data captured by the mobile phone **60** and sent to the monitoring server **30** over a long-range wireless network (e.g., Cellular network). Based on the determined location of the user **50**, the monitoring server **30** determines that the user is away from the property **10** and, therefore, the first detected pattern has been violated. Accordingly, the monitoring server **30** determines that the front door open event on Tuesday at 11 AM detected by the control panel **20** is abnormal and sends an alert to the user **50** indicating the abnormal front door opening. At this time, the monitoring server **30** withholds alerting a central monitoring station server **70** used by a central monitoring station that handles dispatching of emergency services based on alarm conditions detected by monitoring systems. The monitoring server **30** may withhold alerting the central monitoring station server **70** because, although the front door open event is abnormal, the front door open event does not have a high enough degree of abnormality to warrant contacting the central monitoring station server **70** without first alerting the user **50**.

The user **50** may view the alert on the mobile phone **60** and take action with respect to the abnormal front door opening. For example, the user **50** may provide user input indicating that the abnormal front door opening is an actual

alarm condition or that the abnormal front door opening is not an alarm condition and should be ignored by the monitoring system. In this example, the mobile phone **60** receives the user input provided by the user **50** and communicates the received user input to the monitoring server **30**. The monitoring server **30** receives the user input from the mobile phone **60** and, in this case, ignores the abnormal front door opening because the user **50** confirmed that the abnormal front door opening was not an alarm condition.

In the example shown in FIG. 1B, the control panel **20** detects a back door open event on a Wednesday at 2 PM based on output from the back door sensor **26**. The control panel **20** also detects an interior motion sensor event following the back door open event based on output from the motion sensor **24**. In this example, the control panel **20** does not detect an alarm condition based on the back door open event and the motion sensor event because the in-home monitoring system is in an unarmed state (e.g., the user **50** forgot to arm the in-home monitoring system upon leaving). The control panel **20** sends a message to the monitoring server **30** indicating detection of the back door open event on Wednesday at 2 PM followed by the motion sensor event at a time when the in-home monitoring system is in an unarmed state. The monitoring server **30** receives the message from the control panel **20** and compares the back door open event on Wednesday at 2 PM followed by the motion sensor event with the detected patterns **40** that were automatically identified by the monitoring server **30** based on past sensor and other activity collected by the monitoring server **30**. Based on the comparison, the monitoring server **30** determines that the back door open event on Wednesday at 2 PM conflicts with the first detected pattern of no door activity on Monday to Thursday between eight in the morning and five in the afternoon and determines that the order of the back door open event followed by the motion sensor event conflicts with the second detected pattern of a back door open event typically (e.g., always) preceded by an interior motion sensor event.

The monitoring server **30** also determines that the user **50** is away from the property **10** and, therefore, confirms that the first detected pattern and the second detected pattern have been violated. Accordingly, the monitoring server **30** determines that the back door open event on Wednesday at 2 PM followed by the motion sensor event is highly abnormal, as it conflicts with two detected patterns of activity. Based on the determination of highly abnormal activity, the monitoring server **30** sends an alert to the central monitoring station server **70** to indicate a highly abnormal back door entry that needs investigation. In response to the alert, personnel at the central monitoring station take action to confirm whether the highly abnormal back door entry is an actual alarm condition and dispatch emergency personnel to the property **10**, as needed. In this regard, even though the in-home monitoring system is in an unarmed state, the in-home monitoring system is still effective in detecting alarm conditions because the monitoring server **30** is able to detect highly abnormal events and take appropriate action.

In addition, the monitoring server **30** sends an alert to the user **50** indicating that the central monitoring station server **70** has been alerted to a highly abnormal back door entry. The user **50** may view the alert on the mobile phone **60** and take action with respect to the highly abnormal back door entry. For example, the user **50** may provide user input indicating that the highly abnormal back door entry is an actual alarm condition or that the abnormal back door opening is not an alarm condition. In this example, the mobile phone **60** receives the user input provided by the user

**50** and communicates the received user input to the monitoring server **30**. The monitoring server **30** receives the user input from the mobile phone **60** and communicates the user input to the central monitoring station server **70** to assist the central monitoring station server **70** in determining whether the highly abnormal back door entry is an actual alarm condition.

In some implementations, rather than alerting the central station directly in response to the determination of highly abnormal activity, the monitoring server **30** may first control the control panel **20** to sound an alarm at the property **10** (e.g., activate a siren) and provide the user **50** (or another person located at the property **10**) a chance to disarm the alarm before notifying the central station. In these implementations, the monitoring server **30** waits a predetermined period of time (e.g., one minute), monitors for input disarming the alarm, and alerts the central monitoring station server **70** in response to a determination that the predetermined period of time has passed without receipt of input disarming the alarm.

In the example shown in FIG. 1C, the control panel **20** detects a front door open event on a Thursday at 5:30 PM based on output from the front door sensor **22**. In this example, the control panel **20** detects an alarm condition based on the front door open event because the in-home monitoring system is in an armed state. The control panel **20** sends a message to the monitoring server **30** indicating an alarm condition due to detection of the front door open event on Thursday at 5:30 PM at a time when the in-home monitoring system is in an armed state. The monitoring server **30** receives the message from the control panel **20** and compares the front door open event on Thursday at 5:30 PM with the detected patterns **40** that were automatically identified by the monitoring server **30** based on past sensor and other activity collected by the monitoring server **30**. Based on the comparison, the monitoring server **30** determines that the front door open event on Thursday at 5:30 PM is consistent with the third detected pattern that, on Monday to Thursday between five and six in the afternoon, the front door sensor **22** detects opening of the front door.

To confirm whether the front door open event on Thursday at 5:30 PM is consistent with the third detected pattern, the monitoring server **30** determines a location of the user **50** based on a location of the user's mobile phone **60**. Based on the determined location of the user **50**, the monitoring server **30** determines that the user is at the property **10** and, therefore, the front door open event on Thursday at 5:30 PM is consistent with the third detected pattern. Accordingly, the monitoring server **30** determines that the front door open event on Thursday at 5:30 PM is consistent with the third detected pattern detected by the control panel **20** is normal and determines to delay reporting of the alarm condition to the central monitoring station server **70**, thereby enabling the user **50** more time to disable the alarm condition and, potentially, reducing the chance of reporting a false alarm. In this regard, the monitoring server **30** sends a message to the control panel **20** indicating that the control panel should extend the dialer delay to provide the user **50** more time to enter a passcode needed to disarm the in-home monitoring system and also prompt the user **50** to provide input to disarm the in-home monitoring system. If the control panel **20** does not receive input to disarm the in-home monitoring system prior to expiration of the extended dialer delay period, the control panel **20** alerts the central monitoring station server **70** to the detected alarm condition.

FIG. 2 illustrates an example of an electronic system **200** configured to provide surveillance and reporting. The elec-

tronic system **200** includes a network **105**, a monitoring system control unit **110**, one or more user devices **140**, **150**, a monitoring application server **160**, and a central alarm station server **170**. In some examples, the network **105** facilitates communications between the monitoring system control unit **110**, the one or more user devices **140**, **150**, the monitoring application server **160**, and the central alarm station server **170**.

The network **105** is configured to enable exchange of electronic communications between devices connected to the network **105**. For example, the network **105** may be configured to enable exchange of electronic communications between the monitoring system control unit **110**, the one or more user devices **140**, **150**, the monitoring application server **160**, and the central alarm station server **170**. The network **105** may include, for example, one or more of the Internet, Wide Area Networks (WANs), Local Area Networks (LANs), analog or digital wired and wireless telephone networks (e.g., a public switched telephone network (PSTN), Integrated Services Digital Network (ISDN), a cellular network, and Digital Subscriber Line (DSL)), radio, television, cable, satellite, or any other delivery or tunneling mechanism for carrying data. Network **105** may include multiple networks or subnetworks, each of which may include, for example, a wired or wireless data pathway. The network **105** may include a circuit-switched network, a packet-switched data network, or any other network able to carry electronic communications (e.g., data or voice communications). For example, the network **105** may include networks based on the Internet protocol (IP), asynchronous transfer mode (ATM), the PSTN, packet-switched networks based on IP, X.25, or Frame Relay, or other comparable technologies and may support voice using, for example, VoIP, or other comparable protocols used for voice communications. The network **105** may include one or more networks that include wireless data channels and wireless voice channels. The network **105** may be a wireless network, a broadband network, or a combination of networks including a wireless network and a broadband network.

The monitoring system control unit **110** includes a controller **112** and a network module **114**. The controller **112** is configured to control a monitoring system (e.g., a home alarm or security system) that includes the monitoring system control unit **110**. In some examples, the controller **112** may include a processor or other control circuitry configured to execute instructions of a program that controls operation of an alarm system. In these examples, the controller **112** may be configured to receive input from sensors, detectors, or other devices included in the alarm system and control operations of devices included in the alarm system or other household devices (e.g., a thermostat, an appliance, lights, etc.). For example, the controller **112** may be configured to control operation of the network module **114** included in the monitoring system control unit **110**.

The network module **114** is a communication device configured to exchange communications over the network **105**. The network module **114** may be a wireless communication module configured to exchange wireless communications over the network **105**.

For example, the network module **114** may be a wireless communication device configured to exchange communications over a wireless data channel and a wireless voice channel. In this example, the network module **114** may transmit alarm data over a wireless data channel and establish a two-way voice communication session over a wireless voice channel. The wireless communication device may include one or more of a GSM module, a radio modem,

cellular transmission module, or any type of module configured to exchange communications in one of the following formats: GSM or GPRS, CDMA, EDGE or EGPRS, EV-DO or EVDO, UMTS, or IP.

The network module **114** also may be a wired communication module configured to exchange communications over the network **105** using a wired connection. For instance, the network module **114** may be a modem, a network interface card, or another type of network interface device. The network module **114** may be an Ethernet network card configured to enable the monitoring system control unit **110** to communicate over a local area network and/or the Internet. The network module **114** also may be a voiceband modem configured to enable the alarm panel to communicate over the telephone lines of Plain Old Telephone Systems (POTS).

The monitoring system that includes the monitoring system control unit **110** includes one or more sensors or detectors. For example, the monitoring system may include multiple sensors **120**. The sensors **120** may include a contact sensor, a motion sensor, a glass break sensor, or any other type of sensor included in an alarm system or security system. The sensors **120** also may include an environmental sensor, such as a temperature sensor, a water sensor, a rain sensor, a wind sensor, a light sensor, a smoke detector, a carbon monoxide detector, an air quality sensor, etc. The sensors **120** further may include a health monitoring sensor, such as a prescription bottle sensor that monitors taking of prescriptions, a blood pressure sensor, a blood sugar sensor, a bed mat configured to sense presence of liquid (e.g., bodily fluids) on the bed mat, etc. In some examples, the sensors **120** may include a radio-frequency identification (RFID) sensor that identifies a particular article that includes a pre-assigned RFID tag.

The monitoring system control unit **110** communicates with the module **122** and the camera **130** to perform surveillance or monitoring. The module **122** is connected to one or more lighting systems and is configured to control operation of the one or more lighting systems. The module **122** may control the one or more lighting systems based on commands received from the monitoring system control unit **110**. For instance, the module **122** may cause a lighting system to illuminate an area to provide a better image of the area when captured by a camera **130**.

The camera **130** may be a video/photographic camera or other type of optical sensing device configured to capture images. For instance, the camera **130** may be configured to capture images of an area within a building monitored by the monitoring system control unit **110**. The camera **130** may be configured to capture single, static images of the area and also video images of the area in which multiple images of the area are captured at a relatively high frequency (e.g., thirty images per second). The camera **130** may be controlled based on commands received from the monitoring system control unit **110**.

The camera **130** may be triggered by several different types of techniques. For instance, a Passive Infra Red (PIR) motion sensor may be built into the camera **130** and used to trigger the camera **130** to capture one or more images when motion is detected. The camera **130** also may include a microwave motion sensor built into the camera and used to trigger the camera **130** to capture one or more images when motion is detected. The camera **130** may have a “normally open” or “normally closed” digital input that can trigger capture of one or more images when external sensors (e.g., the sensors **120**, PIR, door/window, etc.) detect motion or other events. In some implementations, the camera **130**

receives a command to capture an image when external devices detect motion or another potential alarm event. The camera **130** may receive the command from the controller **112** or directly from one of the sensors **120**.

In some examples, the camera **130** triggers integrated or external illuminators (e.g., Infra Red, Z-wave controlled “white” lights, lights controlled by the module **122**, etc.) to improve image quality when the scene is dark. An integrated or separate light sensor may be used to determine if illumination is desired and may result in increased image quality.

The camera **130** may be programmed with any combination of time/day schedules, system “arming state”, or other variables to determine whether images should be captured or not when triggers occur. The camera **130** may enter a low-power mode when not capturing images.

In this case, the camera **130** may wake periodically to check for inbound messages from the controller **112**. The camera **130** may be powered by internal, replaceable batteries if located remotely from the monitoring control unit **110**. The camera **130** may employ a small solar cell to recharge the battery when light is available. Alternatively, the camera **130** may be powered by the controller’s **112** power supply if the camera **130** is co-located with the controller **112**.

The sensors **120**, the module **122**, and the camera **130** communicate with the controller **112** over communication links **124**, **126**, and **128**. The communication links **124**, **126**, and **128** may be a wired or wireless data pathway configured to transmit signals from the sensors **120**, the module **122**, and the camera **130** to the controller **112**. The sensors **120**, the module **122**, and the camera **130** may continuously transmit sensed values to the controller **112**, periodically transmit sensed values to the controller **112**, or transmit sensed values to the controller **112** in response to a change in a sensed value.

The communication link **128** over which the camera **130** and the controller **112** communicate may include a local network. The camera **130** and the controller **112** may exchange images and commands over the local network. The local network may include 802.11 “WiFi” wireless Ethernet (e.g., using low-power WiFi chipsets), Z-Wave, Zigbee, Bluetooth, “Homeplug” or other “Powerline” networks that operate over AC wiring, and a Category 5 (CAT5) or Category 6 (CAT6) wired Ethernet network.

The monitoring application server **160** is an electronic device configured to provide monitoring services by exchanging electronic communications with the monitoring system control unit **110**, the one or more user devices **140**, **150**, and the central alarm station server **170** over the network **105**. For example, the monitoring application server **160** may be configured to monitor events (e.g., alarm events) generated by the monitoring system control unit **110**. In this example, the monitoring application server **160** may exchange electronic communications with the network module **114** included in the monitoring system control unit **110** to receive information regarding events (e.g., alarm events) detected by the monitoring system control unit **110**. The monitoring application server **160** also may receive information regarding events (e.g., alarm events) from the one or more user devices **140**, **150**.

In some examples, the monitoring application server **160** may route alarm data received from the network module **114** or the one or more user devices **140**, **150** to the central alarm station server **170**. For example, the monitoring application server **160** may transmit the alarm data to the central alarm station server **170** over the network **105**.

The monitoring application server **160** may store sensor and image data received from the monitoring system and perform analysis of sensor and image data received from the monitoring system. Based on the analysis, the monitoring application server **160** may communicate with and control aspects of the monitoring system control unit **110** or the one or more user devices **140, 150**.

The central alarm station server **170** is an electronic device configured to provide alarm monitoring service by exchanging communications with the monitoring system control unit **110**, the one or more mobile devices **140, 150**, and the monitoring application server **160** over the network **105**. For example, the central alarm station server **170** may be configured to monitor alarm events generated by the monitoring system control unit **110**. In this example, the central alarm station server **170** may exchange communications with the network module **114** included in the monitoring system control unit **110** to receive information regarding alarm events detected by the monitoring system control unit **110**. The central alarm station server **170** also may receive information regarding alarm events from the one or more mobile devices **140, 150**.

The central alarm station server **170** is connected to multiple terminals **172** and **174**. The terminals **172** and **174** may be used by operators to process alarm events. For example, the central alarm station server **170** may route alarm data to the terminals **172** and **174** to enable an operator to process the alarm data. The terminals **172** and **174** may include general-purpose computers (e.g., desktop personal computers, workstations, or laptop computers) that are configured to receive alarm data from a server in the central alarm station server **170** and render a display of information based on the alarm data. For instance, the controller **112** may control the network module **114** to transmit, to the central alarm station server **170**, alarm data indicating that a sensor **120** detected a door opening when the monitoring system was armed. The central alarm station server **170** may receive the alarm data and route the alarm data to the terminal **172** for processing by an operator associated with the terminal **172**. The terminal **172** may render a display to the operator that includes information associated with the alarm event (e.g., the name of the user of the alarm system, the address of the building the alarm system is monitoring, the type of alarm event, etc.) and the operator may handle the alarm event based on the displayed information.

In some implementations, the terminals **172** and **174** may be mobile devices or devices designed for a specific function. Although FIG. 2 illustrates two terminals for brevity, actual implementations may include more (and, perhaps, many more) terminals.

The one or more user devices **140, 150** are devices that host and display user interfaces. For instance, the user device **140** is a mobile device that hosts one or more native applications (e.g., the native surveillance application **142**). The user device **140** may be a cellular phone or a non-cellular locally networked device with a display. The user device **140** may include a cell phone, a smart phone, a tablet PC, a personal digital assistant (“PDA”), or any other portable device configured to communicate over a network and display information. For example, implementations may also include Blackberry-type devices (e.g., as provided by Research in Motion), electronic organizers, iPhone-type devices (e.g., as provided by Apple), iPod devices (e.g., as provided by Apple) or other portable music players, other communication devices, and handheld or portable electronic devices for gaming, communications, and/or data organization. The user device **140** may perform functions unrelated

to the monitoring system, such as placing personal telephone calls, playing music, playing video, displaying pictures, browsing the Internet, maintaining an electronic calendar, etc.

The user device **140** includes a native surveillance application **142**. The native surveillance application **142** refers to a software/firmware program running on the corresponding mobile device that enables the user interface and features described throughout. The user device **140** may load or install the native surveillance application **142** based on data received over a network or data received from local media. The native surveillance application **142** runs on mobile devices platforms, such as iPhone, iPod touch, Blackberry, Google Android, Windows Mobile, etc. The native surveillance application **142** enables the user device **140** to receive and process image and sensor data from the monitoring system.

The user device **150** may be a general-purpose computer (e.g., a desktop personal computer, a workstation, or a laptop computer) that is configured to communicate with the monitoring application server **160** and/or the monitoring system control unit **110** over the network **105**. The user device **150** may be configured to display a surveillance monitoring user interface **152** that is generated by the user device **150** or generated by the monitoring application server **160**. For example, the user device **150** may be configured to display a user interface (e.g., a web page) provided by the monitoring application server **160** that enables a user to perceive images captured by the camera **130** and/or reports related to the monitoring system. Although FIG. 2 illustrates two user devices for brevity, actual implementations may include more (and, perhaps, many more) or fewer user devices.

In some implementations, the one or more user devices **140, 150** communicate with and receive monitoring system data from the monitoring system control unit **110** using the communication link **138**. For instance, the one or more user devices **140, 150** may communicate with the monitoring system control unit **110** using various local wireless protocols such as wifi, Bluetooth, zwave, zigbee, HomePlug (ethernet over powerline), or wired protocols such as Ethernet and USB, to connect the one or more user devices **140, 150** to local security and automation equipment. The one or more user devices **140, 150** may connect locally to the monitoring system and its sensors and other devices. The local connection may improve the speed of status and control communications because communicating through the network **105** with a remote server (e.g., the monitoring application server **160**) may be significantly slower.

Although the one or more user devices **140, 150** are shown as communicating with the monitoring system control unit **110**, the one or more user devices **140, 150** may communicate directly with the sensors and other devices controlled by the monitoring system control unit **110**. In some implementations, the one or more user devices **140, 150** replace the monitoring system control unit **110** and perform the functions of the monitoring system control unit **110** for local monitoring and long range/offsite communication.

In other implementations, the one or more user devices **140, 150** receive monitoring system data captured by the monitoring system control unit **110** through the network **105**. The one or more user devices **140, 150** may receive the data from the monitoring system control unit **110** through the network **105** or the monitoring application server **160** may relay data received from the monitoring system control unit **110** to the one or more user devices **140, 150** through the network **105**. In this regard, the monitoring application

## 11

server 160 may facilitate communication between the one or more user devices 140, 150 and the monitoring system.

In some implementations, the one or more user devices 140, 150 may be configured to switch whether the one or more user devices 140, 150 communicate with the monitoring system control unit 110 directly (e.g., through link 138) or through the monitoring application server 160 (e.g., through network 105) based on a location of the one or more user devices 140, 150. For instance, when the one or more user devices 140, 150 are located close to the monitoring system control unit 110 and in range to communicate directly with the monitoring system control unit 110, the one or more user devices 140, 150 use direct communication. When the one or more user devices 140, 150 are located far from the monitoring system control unit 110 and not in range to communicate directly with the monitoring system control unit 110, the one or more user devices 140, 150 use communication through the monitoring application server 160.

Although the one or more user devices 140, 150 are shown as being connected to the network 105, in some implementations, the one or more user devices 140, 150 are not connected to the network 105. In these implementations, the one or more user devices 140, 150 communicate directly with one or more of the monitoring system components and no network (e.g., Internet) connection or reliance on remote servers is needed.

In some implementations, the one or more user devices 140, 150 are used in conjunction with only local sensors and/or local devices in a house. In these implementations, the system 200 only includes the one or more user devices 140, 150, the sensors 120, the module 122, and the camera 130. The one or more user devices 140, 150 receive data directly from the sensors 120, the module 122, and the camera 130 and sends data directly to the sensors 120, the module 122, and the camera 130. The one or more user devices 140, 150 provide the appropriate interfaces/processing to provide visual surveillance and reporting.

In other implementations, the system 200 further includes network 105 and the sensors 120, the module 122, and the camera 130 are configured to communicate sensor and image data to the one or more user devices 140, 150 over network 105 (e.g., the Internet, cellular network, etc.). In yet another implementation, the sensors 120, the module 122, and the camera 130 (or a component, such as a bridge/router) are intelligent enough to change the communication pathway from a direct local pathway when the one or more user devices 140, 150 are in close physical proximity to the sensors 120, the module 122, and the camera 130 to a pathway over network 105 when the one or more user devices 140, 150 are farther from the sensors 120, the module 122, and the camera 130. In some examples, the system leverages GPS information from the one or more user devices 140, 150 to determine whether the one or more user devices 140, 150 are close enough to the sensors 120, the module 122, and the camera 130 to use the direct local pathway or whether the one or more user devices 140, 150 are far enough from the sensors 120, the module 122, and the camera 130 that the pathway over network 105 is required. In other examples, the system leverages status communications (e.g., pinging) between the one or more user devices 140, 150 and the sensors 120, the module 122, and the camera 130 to determine whether communication using the direct local pathway is possible. If communication using the direct local pathway is possible, the one or more user devices 140, 150 communicate with the sensors 120, the module 122, and the camera 130 using the direct local

## 12

pathway. If communication using the direct local pathway is not possible, the one or more user devices 140, 150 communicate with the sensors 120, the module 122, and the camera 130 using the pathway over network 105.

In some implementations, the system 200 provides end users with access to images captured by the camera 130 to aid in decision making. The system 200 may transmit the images captured by the camera 130 over a wireless WAN network to the user devices 140, 150. Because transmission over a wireless WAN network may be relatively expensive, the system 200 uses several techniques to reduce costs while providing access to significant levels of useful visual information.

In some implementations, a state of the monitoring system and other events sensed by the monitoring system may be used to enable/disable video/image recording devices (e.g., the camera 130). In these implementations, the camera 130 may be set to capture images on a periodic basis when the alarm system is armed in an “Away” state, but set not to capture images when the alarm system is armed in a “Stay” state or disarmed. In addition, the camera 130 may be triggered to begin capturing images when the alarm system detects an event, such as an alarm event, a door opening event for a door that leads to an area within a field of view of the camera 130, or motion in the area within the field of view of the camera 130. In other implementations, the camera 130 may capture images continuously, but the captured images may be stored or transmitted over a network when needed.

In some implementations, one or more of the components of the system 200 (e.g., the monitoring application server 160) may be configured to operate as an aberration engine. The aberration engine may automatically detect unusual/suspicious behavior associated with a building monitored by the system 200 and alert one or more users of the system 200 when unusual/suspicious behavior is detected. Because many people, at times, do not arm their security systems, the aberration engine attempts to detect unusual/suspicious behavior even when the security system is not in an armed state. In this regard, the aberration engine allows a security system to remain useful while it is disarmed.

The aberration engine may consider any inputs and data related to the system 200 to detect unusual/suspicious behavior. For instance, the inputs to the aberration engine may include:

- 1) Historical sensor data
- 2) Current status of the security system
- 3) Other current status information
  - a. Car or smartphone locations may be considered
- 4) The customer’s historical responses to aberration engine alerts
- 5) A customer-specified level of sensitivity/risk for each sensor, and some measure of how much false alarms bother them

The aberration engine may provide any type of output or report based on detection of unusual/suspicious behavior. For example, the output of the aberration engine may be an alert that includes:

- 1) The event(s) that triggered the alert
- 2) Some measure of how unusual this behavior is based on history of the system 200
- 3) Some actions the customer can take
  - a. Notify the Central Station
  - b. View video
  - c. Ignore it
  - d. Ignore it, and tell us not to alert about things like this again

- 4) Activation of an alarm (e.g., siren) at a monitored property and initiation of a dialer delay period
  - a. A user may deactivate the alarm by providing appropriate input prior to expiration of the dialer delay period
  - b. If the dialer delay period expires prior to receipt of input that deactivates the alarm, the central station is notified

In operation, the aberration engine uses statistical analysis to decide what is “normal” and what is “abnormal.” The aberration engine may use three main things to determine what is “normal” and what is “abnormal”:

- 1) Timing
  - a. If a sensor is opening at a time of day/day of week during which it has never had any activity before, that is abnormal.
- 2) Order of events
  - a. If there has been no activity for a long time, then the back door opens, then the motion sensor goes off, that is abnormal.
- 3) Other info
  - a. If the front door opens while none of the occupant’s phones/cars are near home, that is abnormal.

The aberration engine also may treat the lack of events as abnormal. For instance, the aberration engine may consider typical alarm system input and typical sensed events and assess whether a lack alarm system input or sensed events gives rise to concern. In some examples, the aberration engine may consider the following factors:

- 1) If the system is typically disarmed between 3:30 and 4:30 PM, but today it was not, then alert.
- 2) If Timmy’s phone typically comes from school along a certain path to home between 3 and 4 PM and today it went somewhere else, alert.
- 3) If the kitchen door is normally opened shortly after the garage door on weekday evenings, but today only the garage door was opened, alert.

The aberration engine may assign an “abnormality score” to each event (not just true/false) and determine whether unusual/suspicious behavior has occurred based on the abnormality scores. For example, a bunch of slightly suspicious events (e.g., events with low to medium abnormality scores) in a short period of time may aggregate to cause the aberration engine to alert the user. In another example, a single event with a large abnormality score may cause the aberration engine to alert the user.

The aberration engine also may determine to send the alert to more people in a more visible way as the likelihood of a real event increases and as the sensitivity/risk associated with the activity increases. For example, if the front door opens in the middle of the day on a weekday, and that happens about once per month, the aberration engine may email the main end user. If the back door opens in the middle of the night while nobody is home and is left open for a threshold period of time, and the jewelry box is opened, the aberration engine may try to notify all users, possibly including the central station.

The aberration engine also may be used in reverse to try to reduce the reporting of false alarms by extending the dialer delay in cases where the alarm goes off based on events that the aberration engine considers to be normal behavior. For example, historical data may suggest that the system is typically (e.g., always) disarmed between six and seven pm on weekdays. In this example, if the front door opens at six-thirty pm as is normal, but the system is not disarmed, the aberration engine would assess the behavior as normal and determine that the potential alarm has a high

probability of being a false alarm. Accordingly, in an effort to reduce false alarms reported to the central station, the aberration engine would extend the dialer delay to allow more time for the user to disarm the security system.

The aberration engine may be run on the panel/firmware, on the backend, or on any other suitable component of the security system. In some examples, functionality of the aberration engine may be distributed among various components of the security system such that some functionality may be implemented by the panel/firmware and other functionality may be implemented by the backend.

In some implementations, all of the processing described throughout this disclosure may be implemented in a monitoring system control panel located inside the property being monitored, as opposed to sending data to an external server for processing. For example, rather than being a separate server located in a remote location, the monitoring application server **160** may be a logical component inside of the monitoring system control unit **110**. In this example, the monitoring system control unit **110** performs the processing of the aberration engine without having to send sensor data to a separate server separated by a network.

In other implementations, all of the processing described throughout this disclosure may be performed on a remote server (e.g., monitoring application server **160**). In these implementations, the monitoring system control panel (or sensors themselves) may send sensor data to the remote server over a network and the remote server may perform all of the aberration engine analysis of the sensor data. For instance, the monitoring system control unit **110** sends all captured sensor data to the monitoring application server **160** and the monitoring application server **160** performs the processing of the aberration engine.

In still further implementations, the processing described throughout this disclosure may be mixed between a monitoring system control panel and a remote server. In these implementations, the monitoring system control panel and the remote server may share operations needed to analyze the sensor data. For instance, the monitoring system control panel may perform the aberration engine analysis of the sensor data collected relatively recently (e.g., sensor data collected within the past three months) and the remote server may perform the aberration engine analysis of the sensor data collected over a longer period of time (e.g., sensor data collected over the past several years). Alternatively, the monitoring system control panel may perform pre-processing of the sensor data, including collection and aggregation of the sensor data, and the remote server may perform the detailed analysis of detecting patterns within the sensor data. In the example shown in FIG. 2, the processing described throughout this disclosure may be mixed between the monitoring system control unit **110** and the monitoring application server **160**.

FIGS. 3, 8, 10, and 12 illustrate example processes. The operations of the example processes are described generally as being performed by the system **200**. The operations of the example processes may be performed by one of the components of the system **200** (e.g., the monitor control unit **110**, the monitoring application server **160**, etc.) or may be performed by any combination of the components of the system **200**. In some implementations, operations of the example processes may be performed by one or more processors included in one or more electronic devices.

FIG. 3 illustrates an example process **300** for taking action related to a monitoring system based on detected patterns of recurring events with aggregated monitoring data. The system **200** collects data sensed by a monitoring system that

monitors a property of a user (310). For example, the system 200 receives, over a network, data describing sensor events detected by sensors fixed at the property of the user. In this example, the sensor events may be contact sensor events detected by door and window sensors located at doors and windows of the property, motion sensor events detected by motion sensors located at the property, and any other type of sensor events detected by other types described throughout this disclosure. The system 200 receives all sensor events detected by the monitoring system, regardless of whether the monitoring system is in an armed state or an unarmed state when the sensor events are detected.

The system 200 aggregates the collected data over a period of a time (320). For instance, the system 200 identifies the property and/or user associated with collected sensor events and stores sensor events collected over time for the identified property and/or user with an indication of the identified property and/or user. In this regard, the system 200 stores the collected sensor events in a manner that enables the system 200 to access all of the collected sensor events for the identified property and/or user. The system 200 may aggregate the collected sensor events over any period of time, including all sensor events collected over years, sensor events collected over a period of one or more months, sensor events collected over a period of one or more weeks, or other suitable time periods that enable the system 200 to detect recurring events in the aggregated sensor data.

The system 200 detects, within the aggregated data, patterns of recurring events (330). For instance, the system 200 analyzes the aggregated data to detect patterns of recurring sensor events in the aggregated data. The system 200 may detect events as events sensed by sensors of the monitoring system as well as a lack of sensor events detected. The system 200 may consider the timing of events, such as events that repeat on a routine basis (e.g., events that occur at the relatively same time everyday day or events that occur at the relatively same time on a particular day of the week). The system 200 also may consider orders in which events occur (e.g., a particular motion sensor event routinely precedes a particular door open event). The order of events may be considered with respect to timing or irrespective of timing.

In detecting patterns, the system 200 may consider any type of historical sensor activity detected by a monitoring system located at a property. The system 200 also may consider other types of activity, such as location data of one or more users of the monitoring system, data collected by sensors of a vehicle of one or more users of the monitoring system, weather data accessible to the monitoring system, or any other type of data that the system 200 is capable of collecting, aggregating, and analyzing.

To detect patterns within the aggregated data, the system 200 may use any type of data mining techniques capable of detecting patterns of recurring events. The system 200 may perform an automatic or semi-automatic analysis of relatively large quantities of sensor data to extract previously unknown interesting patterns, such as identifying groups of sensor events using cluster analysis, identifying unusual sensor events using anomaly detection, and identifying dependencies using association rule mining. Based on the patterns detected, the system 200 may assign a confidence score for each pattern that reflects a level of confidence that the detected pattern is actually a pattern of recurring events that will be observed in the future. The system 200 may determine the confidence score based on a percentage of time the pattern has occurred in the past, the amount of data

used in detecting the pattern, and any statistical techniques that assess whether the pattern is a statistically significant pattern of recurring events.

FIG. 4 illustrates an example data record 400 that stores patterns detected within aggregated sensor data and confidence scores for each of the detected patterns. The data record 400 includes a first column 410 for a detected pattern and a second column 420 for a confidence score associated with the pattern stored in the column 410. As shown, a first detected pattern 430 indicates that the system 200 detected a pattern of a lack of sensor activity on Saturdays between seven in the morning to one in the afternoon. The first detected pattern 430 has a confidence score of sixty, which indicates that the pattern is more likely than not, but not overly confident (e.g., no sensor activity on Saturdays between seven in the morning to one in the afternoon has been detected sixty percent of the time).

A second detected pattern 440 indicates that the system 200 detected a pattern of arming the monitoring system in a “Stay” mode by eleven in the evening when all users are detected as being at home. The second detected pattern 440 has a confidence score of ninety, which indicates that the pattern is likely (e.g., arming the monitoring system in a “Stay” mode by eleven in the evening when all users are detected as being at home has occurred ninety percent of the time).

A third detected pattern 450 indicates that the system 200 detected a pattern of arming the monitoring system in an “Away” mode by nine in the morning when all users are detected as being away from home. The third detected pattern 450 has a confidence score of ninety-five, which indicates that the pattern is likely (e.g., arming the monitoring system in an “Away” mode by nine in the morning when all users are detected as being away from home has occurred ninety-five percent of the time).

A fourth detected pattern 460 indicates that the system 200 detected a pattern of window opening events being preceded by interior motion detection events. The window opening events may be for a specific window or all windows in a monitored property. The fourth detected pattern 460 has a confidence score of one hundred, which indicates that the pattern is very likely (e.g., window opening events have been preceded by interior motion detection events one hundred percent of the time).

A fifth detected pattern 470 indicates that the system 200 detected a pattern of back door opening events being preceded by interior motion detection events daily between six to seven in the morning and ten to eleven in the evening. The fifth detected pattern 470 has a confidence score of eighty, which indicates that the pattern is likely (e.g., back door opening events have been preceded by interior motion detection events daily between six to seven in the morning and ten to eleven in the evening eighty percent of the time).

A sixth detected pattern 480 indicates that the system 200 detected a pattern of a lack of sensor activity on Sundays between eight in the morning to noon. The sixth detected pattern 480 has a confidence score of seventy, which indicates that the pattern is more likely than not, but not overly confident (e.g., no sensor activity on Sundays between eight in the morning to noon has been detected seventy percent of the time).

In some implementations, the system 200 uses a threshold confidence score in determining whether or not to detect and continue monitoring a pattern. In these implementations, the system 200 may use a confidence score of sixty as a threshold (e.g., patterns that occur at least sixty percent of the time). Accordingly, patterns having a confidence score

lower than sixty are not included in the data record **400** and do not impact the monitoring system, unless the pattern increases to warrant further consideration (e.g., increases to a confidence score at sixty or above).

Referring again to FIG. **3**, the system **200** takes action related to the monitoring system based on the detected patterns of recurring events (**340**). For instance, the system **200** may suggest rules (e.g., alerts) for the monitoring system based on the detected patterns of recurring events, may automatically set rules (e.g., alerts) for the monitoring system based on the detected patterns of recurring events, and may send alerts to a user or a central monitoring station to indicate detection of abnormal activity. By taking action based on the detected patterns of recurring events, the system **200** may enhance the ease with which a user is able to configure a monitoring system and enable a user to benefit from having a monitoring system, even though the user is not diligent about arming the monitoring system and setting alerting rules for the monitoring system.

FIG. **5** illustrates an example interface **500** that makes suggestions based on the detected patterns of recurring events. The interface **500** may be part of a message (e.g., electronic mail message) sent to a device of a user of a monitoring system or may be displayed when the user of the monitoring system accesses a web page associated with the monitoring system. The system **200** may cause display of the interface **500** when new patterns of recurring events have been detected. The system **200** may cause display of the interface **500** as part of taking action related to the monitoring system based on the detected patterns of recurring events described above with respect to reference numeral **340**.

As shown, the interface **500** includes a list of suggested rules **510**, a confidence **520** that reflects a level of confidence of the system **200** in suggesting the rule, and a number of expected alerts **525** that reflects a number of alerts the system **200** expects to result from the rule over a given time period (e.g., one year). The confidence **520** and the number of expected alerts **525** may assist a user in determining whether or not to adopt a suggested rule. A first suggested rule is to alert the central station and notify the user when the system **200** detects a window opening event without prior detection of an interior motion sensor event. The system **200** suggests the first suggested rule based on the fourth detected pattern **460** that window openings have always been preceded by interior motion sensor events. Accordingly, the system **200** suggests the first suggested rule because historical sensor data confirms that it is highly unlikely that a window opening from outside the property (e.g., without a prior interior motion sensor event) is normal. The interface **500** shows that the system **200** has a confidence level of one hundred for the first suggested rule, which may indicate that the first suggested rule is being suggested based on a pattern that has occurred one hundred percent of the time. The interface **500** also shows that, based on historical sensor data, the system **200** expects to send zero alerts for the first suggested rule over the course of a year.

The interface **500** includes a set control **530** that receives input to set the first suggested rule for the monitoring system. The interface **500** also includes a decline control **532** that receives input to decline the first suggested rule for the monitoring system. The interface **500** further includes a modify control **534** that receives input to accept the first suggested rule for the monitoring system, but in a modified format. The modify control **534** may cause display of another interface that enables a user to provide input to modify the first suggested rule by adding, removing, and/or

changing criteria for meeting the rule and/or changing actions taken when the rule has been met. The system **200** may consider decisions to set, decline, and modify the first suggested rule in future suggestions made to the user.

A second suggested rule is to set an arming reminder at nine in the morning when the system **200** detects all of the users being away from home and detects the monitoring system being in an unarmed state. The system **200** suggests the second suggested rule based on the third detected pattern **450** of arming the monitoring system in an “Away” mode by nine in the morning when all users are detected as being away from home. Accordingly, the system **200** suggests the second suggested rule because historical sensor data confirms that the monitoring system is typically armed by nine in the morning when all users are detected as being away from home. The interface **500** shows that the system **200** has a confidence level of ninety-five for the second suggested rule, which may indicate that the second suggested rule is being suggested based on a pattern that has occurred ninety-five percent of the time. The interface **500** also shows that, based on historical sensor data, the system **200** expects to send two alerts for the second suggested rule over the course of a year.

The interface **500** includes a set control **540** that receives input to set the second suggested rule for the monitoring system. The interface **500** also includes a decline control **542** that receives input to decline the second suggested rule for the monitoring system. The interface **500** further includes a modify control **544** that receives input to accept the second suggested rule for the monitoring system, but in a modified format. The modify control **544** may cause display of another interface that enables a user to provide input to modify the second suggested rule by adding, removing, and/or changing criteria for meeting the rule and/or changing actions taken when the rule has been met. The system **200** may consider decisions to set, decline, and modify the second suggested rule in future suggestions made to the user.

A third suggested rule is to set a notification alert when the system **200** detects activity on Sunday between eight in the morning and noon. The system **200** suggests the third suggested rule based on the sixth detected pattern **480** of a lack of sensor activity on Sundays between eight in the morning to noon. Accordingly, the system **200** suggests the third suggested rule because historical sensor data confirms that the monitoring system does not typically sense activity on Sunday between eight in the morning and noon. The interface **500** shows that the system **200** has a confidence level of seventy for the third suggested rule, which may indicate that the third suggested rule is being suggested based on a pattern that has occurred seventy percent of the time. The interface **500** also shows that, based on historical sensor data, the system **200** expects to send twelve alerts for the first suggested rule over the course of a year.

The interface **500** includes a set control **550** that receives input to set the third suggested rule for the monitoring system. The interface **500** also includes a decline control **552** that receives input to decline the third suggested rule for the monitoring system. The interface **500** further includes a modify control **554** that receives input to accept the third suggested rule for the monitoring system, but in a modified format. The modify control **554** may cause display of another interface that enables a user to provide input to modify the third suggested rule by adding, removing, and/or changing criteria for meeting the rule and/or changing actions taken when the rule has been met. The system **200** may consider decisions to set, decline, and modify the third suggested rule in future suggestions made to the user.

FIG. 6 illustrates an example interface 600 that alerts a user to rules automatically set for a monitoring system based on the detected patterns of recurring events. The system 200 may automatically set the rules without human intervention or any user input. The interface 600 may be part of a message (e.g., electronic mail message) sent to a device of a user of a monitoring system or may be displayed when the user of the monitoring system accesses a web page associated with the monitoring system. The system 200 may cause display of the interface 600 when new patterns of recurring events have been detected and new rules automatically set. The system 200 may cause display of the interface 600 as part of taking action related to the monitoring system based on the detected patterns of recurring events described above with respect to reference numeral 340.

As shown, the interface 600 includes a list of automatically set rules 610 and a confidence 620 that reflects a level of confidence of the system 200 in automatically setting the rule. The confidence 620 may assist a user in determining whether or not to confirm or remove an automatically set rule. A first rule is to automatically arm the system to “Stay” when all users are detected as being home and system is unarmed at 11 PM. The system 200 automatically sets the first rule based on the second detected pattern 440 that the system 200 detected a pattern of arming the monitoring system in a “Stay” mode by eleven in the evening when all users are detected as being at home. Accordingly, the system 200 automatically set the first rule because historical sensor data confirms that it is likely that the users of the monitoring system like to have the monitoring system set in the “Stay” mode by eleven in the evening when all users are detected as being at home and the automatic arming addresses situations in which the users forget to set the monitoring system in the “Stay” mode without waking sleeping users with an alert. The interface 600 shows that the system 200 has a confidence level of ninety for the first rule, which may indicate that the first rule was automatically set based on a pattern that has occurred ninety percent of the time.

The interface 600 includes a confirm control 630 that receives input to confirm that the first rule should be set for the monitoring system. The interface 600 also includes a remove control 632 that receives input to remove the first rule for the monitoring system. The interface 600 further includes a modify control 634 that receives input to confirm that the first rule should be set for the monitoring system, but in a modified format. The modify control 634 may cause display of another interface that enables a user to provide input to modify the first rule by adding, removing, and/or changing criteria for meeting the rule and/or changing actions taken when the rule has been met. The system 200 may consider decisions to confirm, remove, and modify the first rule in future automatic setting of rules for the monitoring system of the user.

A second rule is to, when the system is armed “Stay,” delay activating a siren and delay alerting the central station for an alarm condition detected based on a back door open event when the back door open event occurs between 6 AM to 7 AM or 10 PM to 11 PM and is preceded by an interior motion sensor event. The system 200 automatically sets the second rule based on the fifth detected pattern 470 that the system 200 detected a pattern of back door opening events being preceded by interior motion detection events daily between six to seven in the morning and ten to eleven in the evening. Accordingly, the system 200 automatically set the second rule because historical sensor data confirms that it is likely that the user of the monitoring system opening the back door from inside of the home between 6 AM to 7 AM

or 10 PM to 11 PM is normal and, therefore, the second rule gives the user more time to disarm the monitoring system prior to taking action for an alarm condition. The interface 600 shows that the system 200 has a confidence level of eighty for the second rule, which may indicate that the second rule was automatically set based on a pattern that has occurred eighty percent of the time.

The interface 600 includes a confirm control 640 that receives input to confirm that the second rule should be set for the monitoring system. The interface 600 also includes a remove control 642 that receives input to remove the second rule for the monitoring system. The interface 600 further includes a modify control 644 that receives input to confirm that the second rule should be set for the monitoring system, but in a modified format. The modify control 644 may cause display of another interface that enables a user to provide input to modify the second rule by adding, removing, and/or changing criteria for meeting the rule and/or changing actions taken when the rule has been met. The system 200 may consider decisions to confirm, remove, and modify the second rule in future automatic setting of rules for the monitoring system of the user.

FIG. 7 illustrates an example interface 700 that alerts a user to abnormal activity. The interface 700 may be part of a message (e.g., electronic mail message) sent to a device of a user of a monitoring system when abnormal activity has been detected. The system 200 may cause display of the interface 700 as part of taking action related to the monitoring system based on the detected patterns of recurring events described above with respect to reference numeral 340.

The system 200 may detect abnormal activity based on a series of events that are each slightly abnormal, but, when considered together, suggest abnormal activity. For instance, the system 200 may identify a series of events detected by the monitoring system and determine abnormality measures based on the detected patterns of recurring events within the aggregated data. The determined abnormality measures may include an abnormality measure for each event included in the series of events. The system 200 then may determine an abnormality score for the series of events based on the determined abnormality measures, compare the abnormality score to a threshold, and, based on the comparison, determine that the abnormality score meets the threshold (e.g., the abnormality score is greater than an abnormality threshold). Based on the determination that the abnormality score meets the threshold, the system 200 may send, to the user, an alert including the interface 700, which indicates that the monitoring system has detected abnormal activity at the property of the user.

The interface 700 includes an abnormality measure 710 that reflects a level of abnormality represented by the series of events. The abnormality measure 710 may be determined based on the abnormality score and, as shown, may be represented as a bar that reflects whether the abnormal activity is highly abnormal, moderately abnormal, or slightly abnormal. The abnormality measure 710 provides a quick indication of whether the level of abnormality of the detected activity is relatively low or relatively high and, therefore, may assist the user in determining how closely the user reviews the alert including the interface 700.

The interface 700 also includes a list of events 720 that resulted in the system 200 detecting abnormal activity at the property of the user. The list of events 720 enables a user to review the sensor events that led to the determination of abnormal activity and determine whether the events are normal or related to an alarm condition.

The interface **700** further includes interface controls **730-760** that enable a user to respond and handle the report of abnormal activity. The interface controls **730-760** include a notify central station control **730** that receives user input to indicate that the user believes the abnormal activity is an alarm condition that should be reported to the central station. In response to user activation of the notify central station control **730**, the system **200** receives the indication that the user believes the abnormal activity is an alarm condition and then reports the alarm condition to the central station with an indication that the user has confirmed that the activity is an alarm condition.

The interface controls **730-760** also include a view video control **740** that receives user input to indicate that the user would like to view video of the property to assist in determining whether the activity is normal or an alarm condition. In response to user activation of the view video control **740**, the system **200** receives the indication that the user would like to view video of the property and then sends video captured by a camera located at the property to the user's device for viewing. After viewing the video, the user may provide additional input to indicate whether the activity is normal or an alarm condition.

The interface controls **730-760** further include an ignore control **750** and an ignore and stop alerting control **760**. The ignore control **750** receives user input to indicate that the user would like to ignore the abnormal activity alert, as the user believes the events relate to authorized use of the property. The ignore and stop alerting control **760** receives user input to indicate that the user would like to ignore the abnormal activity alert and also that the user would like to stop receiving alerts related to abnormal activity.

FIG. **8** illustrates an example process **800** for determining an abnormality score and using the abnormality score in deciding whether to take action in response to potentially abnormal activity at a monitored property. The process **800** may be used in taking action related to the monitoring system based on the detected patterns of recurring events referenced above with respect to reference numeral **340**.

The system **200** assigns scores to rules related to detected patterns (**810**). For instance, the system **200** determines an abnormality score to assign to each rule based on how abnormal it is for the one or more events that trigger the rule to occur. The system **200** may determine the abnormality score based on the confidence in the pattern that led to the rule being suggested or automatically set. The system **200** stores the assigned scores in association with the rules.

FIG. **9** illustrates an example data record **900** that stores rules and abnormality scores for each of the rules. The data record **900** includes a first column **910** for a rule used in assessing whether sensor activity is abnormal and a second column **920** for an abnormality score associated with the rule stored in the column **910**. As shown, a first rule **930** indicates that the system **200** considers activity on Saturday between 7 AM and 1 PM to be abnormal. The first rule **930** has an abnormality score of 0.1, which indicates that the rule has a relatively low contribution to detection of abnormal activity. The abnormality score for the first rule **930** may be set based on the first detected pattern **430** described above with respect to FIG. **4**. The abnormality scores may be normalized to values between  $-1.0$  to  $1.0$ .

A second rule **935** indicates that the system **200** considers activity on Sunday between 8 AM and 12 PM to be abnormal. The second rule **935** has an abnormality score of 0.2, which indicates that the rule has a relatively low contribution to detection of abnormal activity. The abnormality score

for the second rule **935** may be set based on the sixth detected pattern **480** described above with respect to FIG. **4**.

A third rule **940** indicates that the system **200** considers activity on Monday to Thursday between 9 AM and 5 PM to be abnormal. The third rule **940** has an abnormality score of 0.4, which indicates that the rule has a relatively medium contribution to detection of abnormal activity.

A fourth rule **945** indicates that the system **200** considers a window opening event that is not preceded by an interior motion sensor event to be abnormal. The fourth rule **945** has an abnormality score of 1.0, which indicates that the rule has a relatively high contribution to detection of abnormal activity. The abnormality score for the fourth rule **945** may be set based on the fourth detected pattern **460** described above with respect to FIG. **4**.

A fifth rule **950** indicates that the system **200** considers a door opening event followed by interior motion detection between 11 PM to 6 AM to be abnormal. The fifth rule **950** has an abnormality score of 0.8, which indicates that the rule has a relatively high contribution to detection of abnormal activity.

A sixth rule **955** indicates that the system **200** considers a user's location being away from home as contributing to activity at the home being considered as abnormal. The sixth rule **955** has an abnormality score of 0.2, which indicates that the rule has a relatively low contribution to detection of abnormal activity.

A seventh rule **960** indicates that the system **200** considers a user's location being at home as contributing against activity at the home being considered as abnormal. The seventh rule **960** has an abnormality score of  $-0.6$ , which indicates that the rule has a relatively medium contribution to detection of activity as being normal.

An eighth rule **965** indicates that the system **200** considers a user's recent trend of ignoring abnormal activity alerts as contributing against activity at the home being considered as abnormal. The eighth rule **965** has an abnormality score of  $-0.2$ , which indicates that the rule has a relatively low contribution to detection of activity as being normal.

Referring again to FIG. **8**, the system **200** compares detected events to the rules related to detected patterns (**820**). For instance, the system **200** detects sensor events captured by sensors located at the property of the user and compares the sensor events to the rules. The system **200** also may detect user location events and compare the user location events to the rules. The system **200** further may detect user input events (e.g., decisions to ignore abnormal activity) and compare the user input events to the rules.

Based on the comparison, the system **200** identifies one or more events that meet one or more of the rules (**830**) and accesses scores associated with the one or more rules (**840**). For example, the system **200** determines whether the sensor events, the user location events, and the user input events match any of the rules related to detected patterns (e.g., the rule stored in the data record **900**). In this example, for each matching rule, the system **200** accesses the abnormality score assigned to the rule.

The system **200** combines the accessed scores to determine an abnormality score for the detected events (**850**). For instance, the system **200** may sum all of the accessed scores to determine a total abnormality score. Other techniques for combining the accessed scores using weights or other mathematical or statistical processed may be used.

The system **200** compares the abnormality score to a threshold (**860**) and, based on the comparison, the system **200** determines whether the abnormality score meets the threshold (**870**). For instance, the system **200** accesses the

threshold and compares the abnormality score to the accessed threshold to determine whether the abnormality score is less than, equal to, or greater than the threshold. The system 200 may determine that the threshold is met using any of the determinations depending on the implementation, such as determining that the threshold is met based on the abnormality score being greater than the threshold or determining that the threshold is met based on the abnormality score being greater than or equal to the threshold.

Based on a determination that the abnormality score meets the threshold, the system 200 takes action for abnormal activity (880). For example, the system 200 sends an alert to the user to indicate detection of abnormal activity that meets the threshold. In this example, the system 200 may send an alert having content similar to that included in the interface 700 described above with respect to FIG. 7.

Based on a determination that the abnormality score does not meet the threshold, the system 200 continues monitoring detected events and updates the abnormality score based on newly detected events and timing of newly detected events (890). For example, the system 200 continues to determine whether newly detected events meet any of the rules, accesses scores for any rules that match the newly detected events, and updates the abnormality score based on the accessed scores for the newly detected events. In this example, the system 200 may add the accessed scores for the newly detected events to the abnormality score and determine whether the new abnormality score reaches the threshold or not.

In addition, the system 200 may consider the timing of the newly detected events in updating the abnormality score. For instance, slightly abnormal events that are detected far apart in terms of timing are unlikely to signal abnormal activity. Accordingly, the system 200 may periodically decrement the abnormality score a certain amount (e.g., decrement the abnormality score by 0.2 every hour). In this regard, the decrementing of the abnormality score reduces the chance of abnormal activity being detected based on slightly abnormal events that are spaced far apart in terms of time.

In some implementations, the system 200 may compute a new abnormality score each time a new rule is violated. In these implementations, the system 200 may compute the new abnormality score based on an abnormality measure for the new rule violation in addition to abnormality measures for any rules that were violated within a threshold period of time (e.g., two hours) of the new rule violation. In this regard, the system 200 only considers events that have occurred relatively closely in time in determining whether the events suggest abnormal activity.

FIG. 10 illustrates an example process 1000 for updating how detected patterns are used in performing monitoring system actions based on user input. The system 200 receives user input related to use of patterns in performing monitoring system actions (1010). For example, the system 200 may receive input indicating the user's general preference for alerting relative to how the system 200 has been alerting the user to abnormal activity. In this example, the system 200 may receive input indicating that the user would like to be alerted more frequently or input indicating the user would like to be alerted less frequently.

In some implementations, the system 200 may receive input related to specific rules or patterns being used by the system 200. In these implementations, the system may receive input to confirm, delete, or modify specific rules or patterns that are used by the system 200.

Based on the user input, the system 200 updates settings related to using patterns to perform monitoring system actions (1020). For example, when the user input indicates the user's general preference for alerting relative to how the system 200 has been alerting the user to abnormal activity, the system 200 updates general settings that apply to all detected patterns and all rules set based on detected patterns. In this example, the system 200 may modify an abnormality threshold used in detecting abnormal activity based on input indicating that the user would like to be alerted more or less frequently. The system 200 also may uniformly modify the abnormality measures or scores assigned to all of the individual rules or detected patterns based on input indicating that the user would like to be alerted more or less frequently. The system 200 further may uniformly modify the confidence level needed to detect a pattern based on input indicating that the user would like to be alerted more or less frequently.

In implementations in which the user input relates to specific rules or patterns being used by the system 200, the system 200 updates settings for the specific rules or patterns. For instance, in accordance with the user input, the system 200 may modify abnormality measures or scores assigned to the specific rules or patterns and may modify the specific rules or patterns by adding, removing, and/or changing criteria for meeting the specific rules or patterns and/or changing actions taken when the specific rules or patterns have been met.

The system 200 uses patterns to perform monitoring system actions based on the updated settings (1030). For instance, the system 200 may use the updated setting in any of the techniques described throughout this disclosure for taking action related to the monitoring system based on the detected patterns of recurring events.

FIG. 11 illustrates an example interface 1100 that enables a user to adjust settings related to using patterns to perform monitoring system actions. The interface 1100 may be part of a message (e.g., electronic mail message) sent to a device of a user of a monitoring system or may be displayed when the user of the monitoring system accesses a web page associated with the monitoring system. The system 200 may cause display of the interface 1100 when new patterns of recurring events have been detected and new rules automatically set. The system 200 may cause display of the interface 1100 as part of receiving user input related to use of patterns in performing monitoring system actions described above with respect to reference numeral 1010.

The interface 1100 includes a just right control 1110, an alert me more control 1120, an alert me less control 1130, and a stop alerting control 1140. The controls 1110-1140 enable a user to provide input indicating the user's general preference for alerting. The just right control 1110 receives input to indicate that the user is satisfied with the alerting that has been provided and would like the alerting to continue in the same manner. In response to receiving user input selecting the just right control 1110, the system 200 maintains settings related to using patterns to perform monitoring system actions without changes.

The alert me more control 1120 receives input to indicate that the user would like to be alerted more to detections of potentially abnormal activity. In response to receiving user input selecting the alert me more control 1120, the system 200 adjusts settings related to using patterns to perform monitoring system actions in a manner that would generate more alerts based on potentially abnormal activity. For instance, the system 200 may lower an abnormality score threshold used in determining whether to send an alert for

abnormal activity. By lowering the threshold, the system **200** sends alerts based on a lower level of abnormal activity, thereby resulting in more alerts. In addition, the system **200** may lower a confidence level needed to detect a pattern of activity. By lowering the confidence level needed to detect a pattern of activity, the system **200** may detect patterns more quickly with less confidence and, therefore, result in alerts for more potential patterns of activity.

The alert me less control **1130** receives input to indicate that the user would like to be alerted less to detections of potentially abnormal activity. In response to receiving user input selecting the alert me less control **1130**, the system **200** adjusts settings related to using patterns to perform monitoring system actions in a manner that would generate fewer alerts based on potentially abnormal activity. For instance, the system **200** may increase an abnormality score threshold used in determining whether to send an alert for abnormal activity. By increasing the threshold, the system **200** sends alerts based on a higher level of abnormal activity, thereby resulting in fewer alerts. In addition, the system **200** may raise a confidence level needed to detect a pattern of activity. By raising the confidence level needed to detect a pattern of activity, the system **200** may take longer to detect patterns and do so with higher confidence, thereby resulting in alerts for fewer potential patterns of activity.

The stop alerting control **1140** receives input to indicate that the user does not wish to receive any alerts related to abnormal activity detected using patterns of recurring events. In response to receiving user input selecting the stop alerting control **1140**, the system **200** stops detecting patterns and stops providing alerts to the user based on detected patterns.

In addition, the interface **1100** includes a list of automatically set rules **1150** and a confidence **1160** that reflects a level of confidence of the system **200** in automatically setting the rule. The interface **1100** also includes a confirm control **1170**, a remove control **1172**, and a modify control **1174** for a first automatically set rule and a confirm control **1180**, a remove control **1182**, and a modify control **1184** for a second automatically set rule. The list **1150** and the confidence **1160** are similar to the list **610** and the confidence **620** described above with respect to FIG. 6. The confirm controls **1170** and **1180**, the remove controls **1172** and **1182**, and the modify controls **1182** and **1184** are similar to the confirm controls **630** and **640**, the remove controls **632** and **642**, and the modify controls **634** and **644** described above with respect to FIG. 6. Inclusion of the confirm controls **1170** and **1180**, the remove controls **1172** and **1182**, and the modify controls **1182** and **1184** in the interface **1100** allow a user to provide input on specific automatically set rules in addition to (or instead of) input indicating the user's general preference for alerting provided through controls **1110-1140**.

FIG. 12 illustrates an example process **1200** for updating rules used in taking action for abnormal events. The system **200** tracks additional events after storing data related to taking action based on detected patterns (**1210**). For example, after performing analysis to detect patterns and set rules for the monitoring system, the system **200** tracks additional events. In this example, the additional events may be additional sensor events detected by sensors located at the monitored property, additional user location events that track a location of mobile devices of users of the monitoring system, additional user input events that track how the user has updated and responded to different action taken by the system **200** in response to detecting patterns, and any other events that are described throughout this disclosure or that may be helpful in detecting patterns that assist in identifying

abnormal activity. In tracking additional events, the system **200** may use techniques similar to those described above with respect to reference numerals **310** and **320** in FIG. 3.

The system **200** analyzes the additional events with respect to the data related to taking action (**1220**). For example, the system **200** may periodically analyze whether the additional events impact the patterns of recurring events previously detected by the system **200**. In this example, the system **200** may, each month, compare additional events detected over the past month with the patterns of recurring events previously detected and determine whether the previously detected patterns still hold. The system **200** also may initiate analysis of additional events based on an amount of additional events tracked reaching a threshold level. In analyzing the additional events with respect to the data related to taking action, the system **200** may use techniques similar to those described above with respect to reference numeral **330** in FIG. 3.

Based on the analysis, the system **200** taking action related to updating rules used in taking action for abnormal events (**1230**). For instance, the system **200** may suggest updates to the rules and/or patterns used in detecting abnormal activity or may automatically make updates to the rules and/or patterns used in detecting abnormal activity. In taking action related to updating rules used in taking action for abnormal events, the system **200** may use techniques similar to those described above with respect to reference numeral **340** in FIG. 3.

FIG. 13 illustrates an example interface **1300** that makes suggestions for updating rules based on changes to detected patterns of recurring events. The interface **1300** may be part of a message (e.g., electronic mail message) sent to a device of a user of a monitoring system or may be displayed when the user of the monitoring system accesses a web page associated with the monitoring system. The system **200** may cause display of the interface **1300** when new events are detected that impact previously recognized patterns of recurring events. The system **200** may cause display of the interface **1300** as part of taking action related to updating rules used in taking action for abnormal events described above with respect to reference numeral **1230**.

As shown, the interface **1300** includes a list of suggested rule modifications **1310** and a confidence **1320** that reflects a level of confidence the system **200** has in the rule. The confidence **1320** may assist a user in determining whether or not to adjust a rule that has been set. A first suggested rule modification is to remove or suspend a notification alert that occurs when the system **200** detects activity on Sunday between eight in the morning and noon. The interface **1300** shows that the confidence level in the rule has dropped from seventy to forty, which may indicate that the pattern that initially resulted in the rule being suggested or automatically set has dropped from occurring seventy percent of the time to only occurring forty percent of the time based on new events detected by the system **200** that conflict with the pattern.

The interface **1300** includes a delete control **1330** that receives input to delete the rule associated with the first suggested rule modification. The interface **1300** also includes a suspend control **1332** that receives input to suspend the rule associated with the first suggested rule modification. The suspend control **1332** may cause the rule to be suspended for a predefined period of time (e.g., one month), may cause the rule to be suspended until the confidence in the rule returns to a threshold level of confidence (e.g., returns to seventy), or may prompt the user for additional input to define the period of time for which the

rule should be suspended. The interface **1300** further includes a modify control **1334** that receives input to retain the rule associated with the first suggested rule modification, but in a modified format. The modify control **1334** may cause display of another interface that enables a user to provide input to modify the rule associated with the first suggested rule modification by adding, removing, and/or changing criteria for meeting the rule and/or changing actions taken when the rule has been met. The user also may ignore the suggestions made in the interface **1300** and, thereby, confirm that the rule associated with the first suggested rule modification should be retained in its current form. The system **200** may consider decisions to delete, suspend, modify, and confirm the rule associated with the first suggested rule modification in future suggestions made to the user.

FIG. **14** illustrates an example interface **1400** that alerts a user to adjustments automatically made to rules set for a monitoring system based on changes to detected patterns of recurring events. The system **200** may automatically make the rule adjustments without human intervention or any user input. The interface **1400** may be part of a message (e.g., electronic mail message) sent to a device of a user of a monitoring system or may be displayed when the user of the monitoring system accesses a web page associated with the monitoring system. The system **200** may cause display of the interface **1400** when new events are detected that impact previously recognized patterns of recurring events and cause automatic adjustments to rules. The system **200** may cause display of the interface **1400** as part of taking action related to updating rules used in taking action for abnormal events described above with respect to reference numeral **1230**.

As shown, the interface **1400** includes a list of automatic adjustments **1410** and a confidence **1420** that reflects a level of confidence of the system **200** has in the rule. The confidence **1420** may assist a user in determining whether or not to confirm or decline an automatic adjustment. A first rule considered activity on Saturday between 7 AM and 1 PM to be abnormal. The system **200** has automatically deleted the first rule by deleting an abnormality score assigned to the first rule. The system **200** automatically deleted the first rule because the confidence level in the rule has dropped from sixty to forty, which may indicate that the pattern that initially resulted in the rule being suggested or automatically set has dropped from occurring sixty percent of the time to only occurring forty percent of the time based on new events detected by the system **200** that conflict with the pattern.

The interface **1400** includes a confirm control **1430** that receives input to confirm that the first rule should be deleted. The interface **1400** also includes a decline control **1432** that receives input to decline the automatic adjustment and maintain the first rule. The interface **1400** further includes a modify control **1434** that receives input to confirm that the first rule should be adjusted, but in a different way. The modify control **1434** may cause display of another interface that enables a user to provide input to modify the first rule by adding, removing, and/or changing criteria for meeting the rule and/or changing actions taken when the rule has been met. The system **200** may consider decisions to confirm, decline, and modify the adjustment to the first rule in future automatic adjustment of rules for the monitoring system of the user.

A second rule considered detection of a window opening event that is not preceded by an interior motion sensor event to be highly abnormal. The second rule was assigned an abnormality score of 1.0 to reflect the high degree of

abnormality associated with the second rule. The system **200** has automatically reduced the abnormality score assigned to the second rule from 1.0 to 0.8. The system **200** automatically reduced the abnormality score for the second rule because the confidence level in the rule has dropped from one hundred to ninety-five, which may indicate that the pattern that initially resulted in the rule being suggested or automatically set has dropped from occurring one hundred percent of the time to only occurring ninety-five percent of the time based on new events detected by the system **200** that conflict with the pattern.

The interface **1400** includes a confirm control **1440** that receives input to confirm that the abnormality score for the second rule should be reduced. The interface **1400** also includes a decline control **1442** that receives input to decline the automatic adjustment and maintain the abnormality score for the second rule. The interface **1400** further includes a modify control **1444** that receives input to confirm that the abnormality score for the second rule should be adjusted, but in a different way. The modify control **1444** may cause display of another interface that enables a user to provide input to modify the second rule by adding, removing, and/or changing criteria for meeting the rule and/or changing actions taken when the rule has been met. The system **200** may consider decisions to confirm, decline, and modify the adjustment to the second rule in future automatic adjustment of rules for the monitoring system of the user.

The described systems, methods, and techniques may be implemented in digital electronic circuitry, computer hardware, firmware, software, or in combinations of these elements. Apparatus implementing these techniques may include appropriate input and output devices, a computer processor, and a computer program product tangibly embodied in a machine-readable storage device for execution by a programmable processor. A process implementing these techniques may be performed by a programmable processor executing a program of instructions to perform desired functions by operating on input data and generating appropriate output. The techniques may be implemented in one or more computer programs that are executable on a programmable system including at least one programmable processor coupled to receive data and instructions from, and to transmit data and instructions to, a data storage system, at least one input device, and at least one output device. Each computer program may be implemented in a high-level procedural or object-oriented programming language, or in assembly or machine language if desired; and in any case, the language may be a compiled or interpreted language. Suitable processors include, by way of example, both general and special purpose microprocessors. Generally, a processor will receive instructions and data from a read-only memory and/or a random access memory. Storage devices suitable for tangibly embodying computer program instructions and data include all forms of non-volatile memory, including by way of example semiconductor memory devices, such as Erasable Programmable Read-Only Memory (EPROM), Electrically Erasable Programmable Read-Only Memory (EEPROM), and flash memory devices; magnetic disks such as internal hard disks and removable disks; magneto-optical disks; and Compact Disc Read-Only Memory (CD-ROM). Any of the foregoing may be supplemented by, or incorporated in, specially-designed ASICs (application-specific integrated circuits).

It will be understood that various modifications may be made. For example, other useful implementations could be achieved if steps of the disclosed techniques were performed in a different order and/or if components in the disclosed

systems were combined in a different manner and/or replaced or supplemented by other components. Accordingly, other implementations are within the scope of the disclosure.

What is claimed is:

1. An electronic system comprising:  
at least one processor; and  
at least one non-transitory computer-readable storage medium coupled to the at least one processor having stored thereon instructions which, when executed by the at least one processor, causes the at least one processor to perform operations comprising:  
monitoring for events detected by a monitoring system located at a property;  
based on the monitoring, identifying at least one event detected by the monitoring system;  
evaluating the at least one event based on data related to the monitoring system that includes at least historical sensor data and current status of the monitoring system;  
based on the evaluation, assigning one or more abnormality scores to the at least one event using statistical analysis to decide an abnormality score based on event timing and an order of events;  
determining whether abnormal activity has occurred based on the one or more abnormality scores assigned by aggregating abnormality scores for multiple events detected over a period of time;  
based on the determination, generating a list of abnormal activities; and  
based on the generated list of abnormal activities, performing an action by automatically removing an abnormal activity from the generated list of abnormal activities.
2. The system of claim 1, wherein assigning one or more abnormality scores to the at least one event comprises assigning one or more abnormality scores that are each more than true or false.
3. The system of claim 1:  
wherein the at least one event detected by the monitoring system while the monitoring system is in an unarmed state comprises multiple events detected by the monitoring system while the monitoring system is in an unarmed state.
4. The system of claim 1:  
wherein the data related to the monitoring system includes additional current status information of devices associated with the monitoring system; and  
wherein evaluating the at least one event comprises evaluating the at least one event based on the additional current status information of devices associated with the monitoring system.
5. The system of claim 4:  
wherein the additional current status information of devices associated with the monitoring system includes car or smartphone locations; and  
wherein evaluating the at least one event based on the additional current status information of devices associated with the monitoring system comprises evaluating the at least one event based on the car or smartphone locations.
6. The system of claim 1:  
wherein the data related to the monitoring system includes historical responses to alerts; and  
wherein evaluating the at least one event comprises evaluating the at least one event based on the historical responses to alerts.

7. The system of claim 1:  
wherein the data related to the monitoring system includes a customer-specified level of sensitivity for each sensor; and  
wherein evaluating the at least one event comprises evaluating the at least one event based on the customer-specified level of sensitivity for each sensor.
8. The system of claim 1:  
wherein the data related to the monitoring system includes a measure of how much false alarms bother a user of the monitoring system; and  
wherein evaluating the at least one event comprises evaluating the at least one event based on the measure of how much false alarms bother a user of the monitoring system.
9. An electronic system comprising:  
at least one processor; and  
at least one non-transitory computer-readable storage medium coupled to the at least one processor having stored thereon instructions which, when executed by the at least one processor, causes the at least one processor to perform operations comprising:  
monitoring for events detected by a monitoring system located at a property;  
based on the monitoring, identifying at least one event in which an action that is normally detected by the monitoring system while the monitoring system is in an unarmed state has not occurred;  
evaluating the at least one event based on data related to the monitoring system that includes at least historical sensor data and current status of the monitoring system;  
based on the evaluation, assigning one or more abnormality scores to the at least one event using statistical analysis to decide an abnormality score based on event timing and an order of events;  
determining whether abnormal activity has occurred based on the one or more abnormality scores assigned by aggregating abnormality scores for multiple events detected over a period of time;  
based on the determination and the unarmed state of the monitoring system, performing an action by automatically removing an abnormal activity from the generated list of abnormal activities.
10. The system of claim 9, wherein assigning one or more abnormality scores to the at least one event comprises assigning one or more abnormality scores that are each more than true or false.
11. The system of claim 9, wherein performing the action comprises automatically updating one or more thresholds used in controlling the monitoring system; and  
wherein the one or more abnormality scores represent a measure of how unusual this behavior is based on history of the monitoring system.
12. The system of claim 9:  
wherein the data related to the monitoring system includes additional current status information of devices associated with the monitoring system; and  
wherein evaluating the at least one event comprises evaluating the at least one event based on the additional current status information of devices associated with the monitoring system.
13. The system of claim 12:  
wherein the additional current status information of devices associated with the monitoring system includes car or smartphone locations; and  
wherein evaluating the at least one event based on the additional current status information of devices asso-

31

ciated with the monitoring system comprises evaluating the at least one event based on the car or smart-phone locations.

**14.** The system of claim **9**:

wherein the data related to the monitoring system includes historical responses to alerts; and

wherein evaluating the at least one event comprises evaluating the at least one event based on the historical responses to alerts.

**15.** The system of claim **9**:

wherein the data related to the monitoring system includes a customer-specified level of sensitivity for each sensor; and

wherein evaluating the at least one event comprises evaluating the at least one event based on the customer-specified level of sensitivity for each sensor.

**16.** The system of claim **9**:

wherein the data related to the monitoring system includes a measure of how much false alarms bother a user of the monitoring system; and

32

wherein evaluating the at least one event comprises evaluating the at least one event based on the measure of how much false alarms bother a user of the monitoring system.

**17.** The system of claim **9**, wherein performing the action based on the determination and the unarmed state of the monitoring system comprises providing an alert that includes the at least one event that triggered the alert, a measure of how unusual this behavior is based on history of the monitoring system, and actions a user of the monitoring system can take in response to the alert.

**18.** The system of claim **9**, wherein assigning one or more abnormality scores to the at least one event comprises using statistical analysis to decide an abnormality score based on event timing and an order of events.
