**ABSTRACT**

A non-dissolvable immersible dispensing puck in the shape of a dissolvable halogen puck when the dissolvable halogen puck is in an undissolved state with the non-dissolvable immersible dispensing puck physically interchangeable with a dissolvable halogen puck when placed in a dispenser for normally holding only a set of halogen pucks to enable a single dispersant dispenser to be converted to a dual dispersant dispenser without changing the structure of the single dispersant dispenser by placing a dispenser within a dispenser wherein only one of the dispensers may be provided with adjustable water ports.

## CROSS REFERENCE TO RELATED APPLICATIONS

This application is a divisional application of patent application Ser. No. 13/998,304 filed Oct. 18, 2013 titled Dispensing Systems (pending), which claims priority from provisional application Ser. 61/795,549 filed Oct. 19, 2012.

## STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH OR DEVELOPMENT

None

## REFERENCE TO A MICROFICHE APPENDIX

None

## BACKGROUND OF THE INVENTION

The concept of cylindrical shapes such as disks is well recognized in the art with the term puck often applied to products that have a cylindrical shape with the height of the product less than the diameter of the product. One well-known cylindrical shape, which comprises a disk of hard rubber, is a hockey puck. Other articles, which also have a cylindrical shape, are often referred to as pucks including halogen pucks such as chlorine pucks and bromine pucks, which are used to sanitize a body of water. Typically, the halogen pucks comprises a water dissolvable halogen in solid form, which can be placed in a dispenser located in or in contact with a body of water such as a pool or a spa to provide for a gradual release of the halogen into the water as the water comes into contact with the outer surfaces of the halogen puck. Typically, the commercially available halogen pucks have a diameter of about 3 inches and a thickness that ranges from about 1 inch to about 1¼ inches. The pucks may be placed in either an inline system or in a floating dispenser.

## SUMMARY OF THE INVENTION

Briefly the invention comprises a non-dissolvable immersible standalone-dispensing puck in the shape of a dissolvable halogen puck when the dissolvable halogen puck is in an undissolved state with the non-dissolvable immersible dispensing puck physically interchangeable with a dissolvable halogen puck when placed in a dispenser for normally holding only a set of halogen pucks. The non-dissolvable immersible dispensing puck, which contains a dispersant, and the halogen puck can be maintained in a dispersing condition when placed alongside each other in a dispenser to convert a single dispersant dispenser to a dual dispersant dispenser where the level of halogen in a body of water can be maintained at a lower level than if only the halogen puck were used in the dispenser. The non-dissolvable immersible dispensing puck allows one to quickly convert a single dispensing dispenser to a dual dispensing dispenser without altering the structure of the dispenser by forming a dispenser within a dispenser.

## BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a perspective view of a non-dissolvable immersible dispensing puck;

FIG. 1A is a perspective view of a halogen puck;

## 2

FIG. 2 is an exploded view of a floating disperser and a non-dissolvable immersible dispensing puck;

FIG. 3 is a sectional view of a floating disperser with the non-dissolvable immersible dispensing puck and a set of halogen pucks located therein;

FIG. 3A is a front view of the floating disperser of FIG. 3 with adjustable water ports located in a first condition;

FIG. 3B is a front view of the floating disperser of FIG. 3 with the adjustable water ports located in a second dispensing condition; and

FIG. 4 is an exploded view of non-dissolvable immersible dispensing puck that is externally securable to the floating disperser.

## DESCRIPTION OF THE PREFERRED EMBODIMENT

FIG. 1 is a perspective view of an example of a non-dissolvable, immersible, non-halogen dispensing puck 10 having a height h and a diametrical width W with the non-dissolvable, immersible, non-halogen dispensing puck having a cylindrical chamber 13 therein with the chamber containing a source of metal ions 14, which for example may be a batch of minerals that release metal ions. In operation, metal ions such as silver ions are released into the body of water as the water comes in contact with the source of metal ions i.e. the minerals 14 contained within the dispensing puck 10. The cylindrical housing 11 of puck 10 comprises a non-water dissolvable cylindrical shell that includes a plurality of water ports 12 located therein for ingress and egress of water to chamber 13 to thereby release metal ions into the body of water as the water contacts the minerals 14. Other sources of ions may be contained within housing 11 without departing from the spirit and scope of the invention.

Typically, housing 11 comprises a rigid, non-water dissolvable material, for example a polymer plastic, which maintains its shape during the dissipation of metal ions therefrom and having a structure that is unaffected by pool or spa water. In this example water ports 12 are located on the sides, top and bottom of the puck 10 although the ports may be located on only the sides of the puck without departing from the spirit and scope of the invention. The purpose of the water ports 12 is to provide for egress and ingress of water into the interior chamber 13 to bring the water into contact with the minerals 14 therein to thereby release metal ions into the body of water. Examples of metal ions suitable for treating a water to reduce harmful organisms include silver ions, copper ions or zinc ions. Although minerals have been described herein it can be appreciated that other types of water treatment materials may be incorporated into the standalone puck 10 that can be inserted into the dispensing chamber of another dispenser. While minerals may be retained within the puck 10 in some cases the water ports may be sized to permit particles to flow there-through. In the example shown housing 11 contains a single chamber 13, however, in some cases one may want to include two or more chambers within puck 10 to provide a benefit of maintaining two or more different dispersants in separate compartments within the puck 10. For example one may want to include dispersants such as one or more of the following silver, silver chloride, clarifiers, algaecides, algaestats, aluminum sulfate, copper sulfate or zinc within a compartment or compartments within the housing 11. The form of the dispersant within the housing 11 may be granular, tabular or other types of solids. For example, suitable dispersants may include dispersants such as granular or tabular DCDMH. In some cases one may seek to replace a

3

halogen puck with one or more dispenser pucks where the dispenser pucks contain different dispersants. In some instances the dispenser puck may occupy more than the space of a single halogen puck and in other cases the dispenser puck may occupy less space than a single halogen puck. Thus, the dispenser puck described herein allows one to convert a halogen dispenser into a device for simultaneously delivery of two or more dispersants to a body of water either through multiple compartments within the dispenser puck or through multiple dispenser pucks which may or may not have the same shape or size as the halogen pucks as long as the dispenser pucks can be fitted into the space normally occupied by the halogen puck in the dispenser. While the invention is ideally suitable for those floating or non-floating dispensers where the halogen pucks are stacked in a face to face condition the invention may be used in those floating or non-floating dispensers where the halogen is in a different shape than a puck. For example, in some cases the halogen within the floating or non-floating dispenser may or may not have a cylindrical shape as well as being located in a random or irregular arrangement within a chamber within the floating or non-floating dispenser.

FIG. 1 shows a perspective view of the non-halogen dispensing puck 10 and FIG. 1A shows a perspective view of a halogen puck 15 revealing that both pucks have the same shape. The non-halogen puck 10 shown in FIG. 1 has a diameter W and a height h and the halogen puck shown in FIG. 1A, which has a top circular surface 15a, a bottom circular surface 15c and a cylindrical sidewall has a thickness designated by  $h_1$  and diameter of the puck is designated by  $W_1$  which generally are the same if not identical dimensions for most commercially available halogen pucks. A feature of the dispensing puck 10 is that the size and shape of dispensing puck 10 is substantially the same as a commercially available halogen puck and thus is interchangeable with a halogen puck 15 contained in a dispenser. Typically, the dispensers that receive the halogen puck contain a cylindrical chamber that has a diameter slightly larger than the halogen puck to allow halogen pucks to be freely stacked within the cylindrical chamber of the dispenser. A floating dispenser may have a cylindrical compartment for typically receiving 2 to 6 halogen pucks although other dispensers may be able to accommodate more or less halogen pucks. While the invention is described in regard to stacked pucks within a chamber in some cases the halogen pucks and the dispensing puck 10 may be held in a non-stacked condition in a dispenser. The feature of interchangeably of the dispensing puck 10 with a halogen puck as described herein enables one to change a single dispersant dispensing device into a dispenser that can simultaneously deliver two or more dispersants into a body of water without having to alter or change the dispenser.

Typically, the solid halogen pucks are manufactured with a width or diameter W of about 3 inches and thickness, which may range from 1 to 1¼ inches. The standardization of the size of halogen pucks, although with variations, has led to creation of pool or spa single dispersant dispensers having a cylindrical chambers where one can stack multiple halogen pucks therein so that the halogen can be dispensed into the body of water over period of time. The single dispersant dispensers are generally oversized sufficiently so as to accommodate the variation in diametrical dimensions and height and width of the halogen pucks which may vary a ¼ inch or more from puck manufacture to puck manufacturer. Such single dispersant dispensing devices, while suitable for dispensing a halogen into a body of water such as a pool or spa are generally not suitable for dispensing a

4

second water treatment material into the body of water since the dispenser contains a single chamber which is not suitable for holding or dispensing other materials into the body of water. While a dispenser with a single compartment for a halogen puck is shown it is envisioned that dispensers that have more than one halogen compartment may be used with the present invention.

FIG. 2 is a perspective view of the non-dissolvable puck 10 of the present invention proximate a prior art conventional floating halogen dispenser 20 which is used to dispense a halogen into a body of water as the dispenser floats in the body of water. Halogen dispenser 20 contains an outer body 21 and a cap 22 with a finger grip 23 for twistingly removing cover 22 from the dispenser so that the halogen pucks therein can be replenished. Located on the bottom of dispenser 20 is a water port adjustment member 32 that can be rotated to provide for greater ingress or egress of water into water ports 31 in the floating dispenser 21 thereby providing adjustable water ports.

FIG. 1 shows the non-dissolvable immersible dispensing puck 10 in the shape of a dissolvable halogen puck 15 (FIG. 1A) when the dissolvable halogen puck 15 is in an undissolved state with the non-dissolvable immersible dispensing puck 10 physically interchangeable with a dissolvable halogen puck 15 when placed in a dispenser for normally holding only a set of halogen pucks. As FIG. 1 shows the non-dissolvable immersible dispensing puck 10 comprises a rigid sidewall 18 joining, a rigid cylindrical bottom member 17 to a rigid cylindrical top member 11 to form a closed container 10 having a dispersant compartment 13 therein with a source of metal ions 14 located in compartment 13. FIG. 1 shows container 10 having a plurality of water ports 12 of fixed area for water to flow in and out of the mineral compartment 13 with a batch of minerals 14 located in compartment 13. A feature of the invention is that the non-dissolvable immersible dispensing puck 10 can be maintained in a dispersing condition when placed alongside a halogen puck in the floating dispenser of FIG. 2. While the water ports 12 are shown as fixed the water ports may also be adjustable without departing from the spirit and scope of the invention.

FIG. 3 is a sectional view of the floating halogen dispenser 20 with the cover removed to reveal an annular flotation member 28 for supporting the dispenser 20 and the contents with at least a portion of the dispenser 20 located above a water air interface, i.e. the water line 9. Dispenser 20 includes a central halogen chamber 25 for receiving and holding four halogen pucks therein with the lower base of dispenser 20 including a set of adjustable openings 31 or water ports to control the amount of water coming into contact with the halogen in chamber 25 and consequently controlling the rate of release of the halogen into the body of water.

In the example of FIG. 3 the floating halogen dispenser 20 has been converted to a multi water treatment dispenser through the placement of a non-dissolvable immersible dispensing puck 10 in the chamber 25 together with the placement of three similar shaped water dissolvable halogen pucks 28. The halogen pucks are stacked in a face-to-face condition on top of the non-dissolvable immersible dispensing puck 10 with the top cylindrical surface 11 forming a separator between the halogen pucks 29 and the dispersant within the non-dissolvable immersible dispensing puck 10.

The conversion of the floating halogen dispenser 20 that contains only a single halogen dispersant into a floating dispenser that contains two different water treatment materials allows one to reduce the level of halogen in the body of water by providing a second water treatment material to

5

supplement the first water treatment material without having to alter the structure of the floating dispenser or obtain a new dispenser. Consequently, the invention herein allows one to obtain the benefit of the combination of two biocides such as a halogen and a source of metal ions, which can reduce the need for a high halogen level that is required if only a single halogen is used as a sanitizer. Typically, systems such as in inline systems, which dispense two dispersants, are known to have dispensers that contain a separate chamber for a halogen and a separate chamber for a source of metal ions whereas the invention described herein uses only a single dispersant chamber to dispenser both dispersants.

In the present example the open area of adjustable water ports **31** at the bottom of floating dispenser **20** can be adjusted to limit the amount of halogen that is released into the body of water by rotation of sleeve **32**, which is rotationally supported by member **35**, about housing **20**. While the nature of most floating dispensers is that they do not provide precise control of the halogen they do allow one to decrease or increase the amount of halogen delivered to the body of water by closing or opening the number of water ports **31** that are visible through sleeve openings **32a**. Sleeve **32** is rotationally supported by housing **20**, typically through a pivot pin such as member **32**. In this example the number of openings **32a** can be aligned with respect to ports **31** in housing sidewall **20** to control the ingress and egress of water into the chamber within the dispenser **20**.

Although the flow area access to the halogen can be limited to thereby reduce the level of halogen in the body of water the level of metal ions released from the non-dissolvable puck **10** can remain relative constant as long as water is present in the chamber in the puck **10**. Thus, in the example shown a conventional halogen dispenser **20** can be converted from a single biocide dispenser to a two biocide dispenser by placing a both a dissolvable halogen puck **29** and a non-dissolvable immersible dispensing puck **10** containing a dispersant, such as a source of metal ions, into the chamber **25** and reducing the flow area of the water ports **31** to lower the level of the first biocide. By lowering the level of the first biocide, in this case the halogen, and introducing a second biocide the body of water can be maintained in condition for human immersion without having the odoriferous presence of a high level of halogen that can accompany dispensers that rely on using only a halogen to sanitize a body of water such as a pool or spa.

A feature of the invention is that sufficient minerals can be placed in the nondissolvable puck **10** to supplement the halogen which can increase the period that the body of water can be maintained in the proper state since the minerals contained in puck **10** can provide metal ions for sanitizing the body of water for a period that is longer than the normal dispensing life of halogen pucks located in a floating dispenser. Thus without increasing the capacity of the dispenser to hold more pucks one can increase the dispensing life of a dispenser by using both halogen pucks and a source of metal ions. The same dispenser can provide a longer period of effective sanitization in a body of water then the same dispenser containing halogen pucks in spite of the fact one of the halogen pucks has been replaced with the mineral puck. Thus, a decrease in the rate of halogen released into the body of water can be used to lengthen the effective dispensing life of the dispenser since the biocide dispersant from the puck **10** supplements the halogen sanitization of the body of water. While results may vary with different dispensers one may able to lengthen the period that an effective amount of halogen is present in the dispenser from days to weeks when the halogen biocide is supplemented by a

6

second biocide. Consequently, one lengthens the sanitizing life of the dispenser even though one of the halogen pucks may be replaced with a non-dissolvable immersible dispensing puck containing a source of metal ions. Thus reducing the consumers need to replenish the biocides in the floating dispenser **20**.

As less halogen is required when a supplemental biocide is used, such as a source of metal ions, the open area of the water ports of dispenser ports **31** can be reduced by rotating shutter **32** to lessen the area for flow therethrough to thereby lessen the rate that water comes into contact with the halogen. In practice the flow thorough area of the ports in the non-dissolve puck may be coordinated with the flow through area of the openings into the halogen chamber **25** so that under the normal dispensing conditions the halogen and the metal ions create a balance that maintains the body of water free of harmful organisms while at the same time maintains the halogen at levels which are less than if the halogen was used as the sole sanitizing agent to maintain the body of water in a sanitized condition for human immersion or recreational use.

FIG. **3** shows a sectional view of cylindrical halogen dispenser **20** having a single dispersant chamber **25** for normally delivering a single dispersant with the dispenser comprising a housing **20a** having a cylindrical halogen chamber **25**, which normally holds a plurality of halogen pucks **29**. In the example of FIG. **3** a non-dissolvable immersible dispensing puck **10** having an interchangeable shape with a halogen puck **29** has been placed in halogen chamber **25** and occupies the space, which would normally contain an additional halogen puck. FIG. **3** shows the dispenser **20** contains a non-dissolvable immersible dispensing puck **10** and a plurality of halogen pucks, which in this case is 3, for simultaneously dispensing dispersants from both the non-dissolvable immersible dispensing puck **10** and the halogen pucks. In the example shown the mineral puck **10** retains its shape while the halogen pucks **29** change their shape as they are dissipated into the body of water.

FIG. **4** shows another example of a method and apparatus for converting a single halogen dispenser into a dual dispenser with the halogen dispenser **40** having a cap **41** for insertion of a halogen puck therein. The dispenser includes an upper body **42** with a flotation member therein (not shown) and a frusto conical wall **43** that connects to the base **44** that includes a set of ports **45** and a rotateable sleeve **44** to permit ingress and egress of water into the halogen pucks that are located in the dispenser **40**. In this example, the non-dissolvable immersible puck **46**, which contains a source of metal ions, has been fitted with a set of axially extending elongated resilient strips **47** that extend around the periphery of the puck **46**. Each of the strips **48** include a lip **48** for engaging a feature of the dispenser **40** to enable the puck **46** to be mounted externally to the halogen chamber in the dispenser **40**. A feature of this example is that the working life of the dispenser can be extended in two ways. The first is that the use of the external puck **10** does not occupy any space in the internal halogen chamber and thus does not affect the normal life of the halogen even if the rate of halogen dissipation was kept constant. The second is that because the level of halogen can be reduced the dispenser has a longer life. Consequently, through the external attachment of the second biocide dispenser to the halogen dispenser one can further increase the time between the addition of halogen to the dispenser **40**. In the event the weight of the extra external mineral puck **46** causes the dispenser **40** to sink the dispenser will automatically surface once the halogen pucks begin to dissipate. Thus, a feature of the

invention is that in some cases one can actually add the dispensing puck **10** to the exterior of a floating dispenser and not replace the internal space for the halogen pucks. In the event the external puck **10** causes the floating dispenser to sink, the performance of the floating dispenser would be unaffected since the floating dispenser will automatically surface once the halogen pucks are partially consumed.

An additional feature of the invention is illustrated in FIG. 3A and FIG. 3B which shows the sanitization setting on the floating dispenser in FIG. 3B has a larger open area **31** than the open area **31** of FIG. 3A. Typically, the setting as shown in FIG. 3B would be a setting where the water ports have more open area and would be used when only halogen is present in the floating dispenser and the setting shown in FIG. 3A is the setting used when the floating dispenser contains both a halogen puck **29** and a non-dissolvable immersible dispensing puck **10** since the water port area **31** has less open area than shown in FIG. 3B.

FIG. 3 also illustrates the method of converting a floating dispenser **20** normally having only a single dispersant chamber **25** and a single dispersant sanitizing mode to a dual dispersant sanitizing mode without altering the structure of the floating dispenser and at the same time requiring less halogen to maintain a body of water in a sanitized condition by placing both a halogen puck and a nondissolvable mineral puck **10** containing a source of metal ions in the single dispersant chamber **25**. FIG. 3 shows that one stacks a plurality of water dissolvable halogen pucks **29** and the nondissolvable mineral puck **10** on top of each other and in a face-to-face condition in the single halogen dispersant chamber **25** with the nondissolvable mineral puck **10** having an interchangeable shape with each of the plurality of water dissolvable halogen pucks **29**. Once the sanitization pucks **10** and **29** are placed in the halogen chamber **25** one selects a dual dispersant water port sanitizing setting, which has lesser area of water ports than in the single dispersant mode, such as shown in FIG. 3A, for sanitizing a body of water with at least two dispersants. The dual sanitizing water port setting on the floating dispenser has less open port area for egress and egress of water therethrough than a single dispersant water port where the sanitizing setting is for a stack of only water dissolvable halogen pucks therein. FIG. 3B illustrates the large area of open water ports **31** when the floating dispenser is in only the halogen-dispensing mode.

Once the floating dispenser **20** has been properly set one places the dispenser **20** with the nondissolvable mineral puck **10** and the water dissolvable halogen pucks **29** in the body of water to bring the nondissolvable mineral puck **10** and the water dissolvable halogen pucks **29** into a water release condition for simultaneously releasing both metal ions and a halogen through water port **31** of the floating dispenser **20** where the water port **31** is located below a water line **9** to thereby maintain the body of water in a halogen and metal ion sanitized condition through the use of both halogen pucks **29** and a mineral puck **10**.

Thus, with the use of both halogen pucks **29** and the non-dissolvable immersible dispensing puck **10** one can decrease the halogen level in a pool or spa having a floating halogen dispenser through manipulation or adjustment of the open area of water ports **31**. Thus, a needed level of halogen can be reduced when both the halogen **29** and the dispensing puck **10** are used to maintain the pool or spa in sanitized condition for human immersion. For example when halogen is used alone a level of halogen in excess of 2 ppm in the pool or spa may be necessary but when used in combination with a mineral puck the level of halogen such as chlorine can be less than 2 ppm.

To effect the change from a single dispersant to a dual dispersant dispenser one can determine a first water port setting of the floating dispenser **20** that maintains a pool or spa in a safe condition for human contact over a first sanitation period when only a set of halogen pucks are located in the floating dispenser. One places at least one mineral puck **10** in a halogen chamber **25** of the floating halogen as shown in FIG. 3 wherein the weight of the mineral puck **10** is equal or less than the weight the halogen puck **29**. Next one can convert the dispenser from a single dispersing mode to a dual dispersing mode by placing a plurality of halogen pucks **29** in a halogen chamber **25** (see FIG. 3) in the floating dispenser **40**. Next, one reduces the water port setting from the first water port setting (FIG. 3B) to reduce the halogen level to a normally unsafe level (FIG. 3A) if only a halogen were used alone but to a level that sanitizes the water when used in conjunction with minerals from dispensing puck **10**. Next, one places the floating dispenser in the pool or spa (not shown) to maintain the pool or spa in a sanitized condition through dispersion of both a halogen and a mineral from the floating halogen dispenser **20**.

A benefit of the method of using two dispersants for sanitizing a body of water is that the least two dispersants can provide a longer sanitizing period then if only halogen pucks **29** were used even though at least one of the halogen pucks in the floating dispenser **20** may have been replaced by the nondissolvable cylindrical mineral puck **10** (FIG. 3).

For example, one can decrease the halogen content in a pool or spa having a floating halogen dispenser **20** through the adjustable water ports **31**. When the halogen pucks are used alone one normally maintains the pool or spa in a sanitized condition for human immersion solely through halogen dispersion from a set of halogen pucks in the halogen dispenser by maintaining a level of halogen in excess of 2 ppm in the pool or spa if the halogen is chlorine. To convert from a single dispersant dispensing mode to a dual dispensing mode one may determine a first water port setting of the floating dispenser that maintains a pool or spa in a safe condition for human contact over a first sanitation period when only the set of halogen pucks are located in the floating dispenser in FIG. 3B. Next, one places at least one mineral puck **10** in a halogen chamber **25** of the floating dispenser **20** wherein the weight of the mineral puck **10** is preferably equal or less than the weight of a halogen puck **29**. FIG. 3 shows one having placed a plurality of halogen pucks **29** in a halogen chamber **25** in the floating dispenser. Next one reduces the water port setting from the first water port setting (as shown in FIG. 3B) to the second water port setting (as shown in FIG. 3A) to reduce the halogen level to a normally unsafe level if only a halogen were used alone but to a lower halogen level that sanitizes the water when the halogen is used in conjunction with a dispensing device such as the mineral puck **10**. For example, less than 2 ppm of halogen if the halogen is chlorine although other levels of halogen may be selected based on water conditions as well as the type of halogen selected. By placing the floating dispenser **20** in the pool or spa one can maintain the pool or spa in a sanitized condition through dispersion of both a halogen and a mineral from the floating halogen dispenser **20**. The method of replacing at least one of the halogen pucks, which for example may be a chlorine or a bromine puck, with a non-dissolvable immersible dispensing puck **10** in the shape of a dissolvable halogen puck **29** to form a dispenser within a dispenser where only one of the dispenser has adjustable water ports can be used with other types of

dispensers including non-floating dispensers without departing from the spirit and scope of the invention.

The non-dissolvable dispenser puck has been described herein as having a housing with a cylindrical shape and a single compartment therein, however, it is envisioned that the housing may have other shapes including those shapes, which may or may not mimic a halogen dispersant. For example, housing shapes other than cylindrical may be used as long as the housing has a shape and size such that the housing can be placed in a space normally occupied by a halogen puck or pucks in a dispenser. The term puck has been used herein to describe both the halogen dispersant and a container for holding a further dispersant that can be placed into a chamber of a dispenser that normally holds only a halogen. The halogen puck may take a variety of shapes or sizes but as used herein the halogen puck is a solid that dissipates into a body of water when placed in contact with a body of water, which may include bodies of water besides pools and spas. While the use of a mineral has been described as a preferred dispersant for placement in the dispensing puck other non-halogen dispersants may be used in conjunction with the halogen without departing from the spirit and scope of the invention. Similarly, the shape and size of the halogen puck may not be the same as the shape or size of the non-dissolvable puck that holds the second biocide and the pucks may or may not be stacked in the dispersant chamber of the halogen dispenser.

A further feature of the invention is that the non-dissolvable immersible dispensing puck can take advantage of different dispersant rates to maintain the proper level of different dispersants within a body of water. Thus, dispenser puck **10**, which is a standalone dispenser, includes a set of water ports **12** for water access to a dispersant, such as minerals, located within the non-dissolvable immersible dispensing puck and the control of the adjustable water port of the dispenser **20** for halogen dispersal is independent of a control of a dispersant from the non-dissolvable immersible dispensing puck **10** as long as the adjustable water ports **31** are maintained in an open condition to permit water access to the dispersants within the dispenser puck **10**.

We claim:

**1.** The method of converting a floating dispenser with a set of water ports located therein from a single dispersant mode to a dual dispersant mode without altering the structure of the floating dispenser where the floating dispenser in the single dispersant mode includes a flotation member with a single halogen dispersant chamber containing a plurality of halogen pucks therein as a sanitizing agent with the single halogen dispersant chamber located partially within the flotation member with a conversion from the single dispersant mode to the dual dispersant mode obtained by replacing a one of the plurality of halogen pucks with a similar shaped stand alone nondissolvable mineral puck having a set of water ports therein for dispensing a further sanitizing agent from within the mineral puck into the floating dispenser with the floating dispenser simultaneously dispensing both the sanitizing agent and the further sanitizing agent from the floating dispenser into a body of water where the dual dispersant mode comprises delivery of the sanitizing agent and the further sanitizing agent into the body of water through the set of water ports located in the floating dispenser to thereby change the floating dispenser from the single dispersant mode to the dual dispersant mode without altering the structure of the floating dispenser.

**2.** The method of claim **1** wherein the further sanitizing agent delivered from the mineral puck are metal ions.

**3.** The method of claim **2** wherein the floating dispenser set of further water ports are adjustable water ports.

**4.** The method of claim **2** including stacking the plurality halogen pucks and the nondissolvable puck on top of each other and in a face-to-face condition in the single dispersant chamber with the nondissolvable puck having an interchangeable shape with each of the plurality of halogen pucks.

**5.** The method of claim **1** including stacking at least three water dissolvable halogen pucks on top of the nondissolvable puck and the ingress and egress of water in nondissolvable puck occurs through the set of water ports in a rigid sidewall of the nondissolvable puck.

**6.** The method of claim **1** wherein a level of halogen in the pool or spa is maintained at least 2 ppm when the halogen is chlorine through a water port adjustment on the dispenser.
