(57) **ABSTRACT**

[Object] To provide a communication device and a communication method which are capable of achieving both an improvement in reliability of communication in which a frame is transmitted to a plurality of destinations and effective use of wireless communication resources.

[Solution] The communication device includes: a communication unit configured to perform communication of a frame. The communication unit transmits a transmission acknowledgment request frame for a transmission acknowledgment response frame including frequency allocation information specifying a transmission frequency of the transmission acknowledgment response frame, and receives the transmission acknowledgment response frame which has undergone frequency division multiplexing, on the basis of the frequency allocation information.

## COMMUNICATION DEVICE AND COMMUNICATION METHOD

### CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a continuation of U.S. application Ser. No. 15/568,860, filed Oct. 24, 2017, which is based on PCT filing PCT/JP2016/062163, filed Apr. 15, 2016, and claims priority to JP 2015-135956, filed Jul. 7, 2015, the entire contents of each are incorporated herein by reference.

### TECHNICAL FIELD

The present disclosure relates to communication devices and communication methods.

### BACKGROUND ART

In recent years, wireless local area networks (LANs) as typified by IEEE (Institute of Electrical and Electronics Engineers) 802.11 have been widespread. In addition, along with the widespread use of wireless LANs, products supporting the wireless LANs have been increasing.

On the other hand, techniques for efficiently communicating with a plurality of communication devices have been developed. As such a technique, for example, a multicast scheme of transmitting frames to one or more communication devices at a time is known.

Here, there are cases in which, in order to improve reliability of communication, it is desirable to perform a transmission acknowledgment for frames (hereinafter also referred to as "acknowledgment (ACK)") for multicast frames, similarly to unicast frames. As such transmission acknowledgment, a Block ACK (BA) for transmission acknowledgment for a plurality of frames is known.

For example, the invention related to a wireless communication device that performs transmission of a Block Ack Request (BAR) frame indicating a transmission request for a BA frame and reception of a BA frame serving as a response to the BAR frame for each terminal in order of time after a multicast frame is transmitted to each terminal is disclosed in Patent Literature 1.

### CITATION LIST

#### Patent Literature

Patent Literature 1: JP 2009-049704A

### DISCLOSURE OF INVENTION

#### Technical Problem

However, in the invention disclosed in Patent Literature 1, it is difficult to efficiently use wireless communication resources. For example, wireless communication resources for transmission acknowledgment for multicast frames are chronologically allocated to each terminal serving as a transmission acknowledgment target. For this reason, there are cases in which it is difficult to allocate wireless communication resources to other communication until the transmission acknowledgment for all terminals is completed.

Further, the above-mentioned problem is not limited to the multicast communication but may occur similarly even

2

in other communication such as frame multiplex communication in which a frame is transmitted to a plurality of destinations.

In this regard, the present disclosure proposes a communication device and a communication method which are novel and improved and capable of achieving both an improvement in reliability of communication in which a frame is transmitted to a plurality of destinations and effective use of wireless communication resources.

#### Solution to Problem

According to the present disclosure, there is provided a communication device including: a communication unit configured to perform communication of a frame. The communication unit transmits a transmission acknowledgment request frame for a transmission acknowledgment response frame including frequency allocation information specifying a transmission frequency of the transmission acknowledgment response frame, and receives the transmission acknowledgment response frame which has undergone frequency division multiplexing, on the basis of the frequency allocation information.

In addition, according to the present disclosure, there is provided a communication device including: a communication unit configured to perform communication of a frame. The communication unit receives a transmission acknowledgment request frame for a transmission acknowledgment response frame including frequency allocation information specifying a transmission frequency of the transmission acknowledgment response frame, and transmits the transmission acknowledgment response frame on the basis of the frequency allocation information. The transmission acknowledgment response frame undergoes frequency division multiplexing.

In addition, according to the present disclosure, there is provided a communication method including: transmitting, by a communication unit configured to perform communication of a frame, a transmission acknowledgment request frame for a transmission acknowledgment response frame including frequency allocation information specifying a transmission frequency of the transmission acknowledgment response frame; and receiving the transmission acknowledgment response frame which has undergone frequency division multiplexing, on the basis of the frequency allocation information.

In addition, according to the present disclosure, there is provided a communication method including: receiving, by a communication unit configured to perform communication of a frame, a transmission acknowledgment request frame for a transmission acknowledgment response frame including frequency allocation information specifying a transmission frequency of the transmission acknowledgment response frame; and transmitting the transmission acknowledgment response frame on the basis of the frequency allocation information. The transmission acknowledgment response frame undergoes frequency division multiplexing.

#### Advantageous Effects of Invention

As described above, according to the present disclosure, a communication device and a communication method which are capable of achieving both an improvement in reliability of communication in which a frame is transmitted to a plurality of destinations and effective use of wireless communication resources are provided. Note that the effects described above are not necessarily limitative. With or in the

place of the above effects, there may be achieved any one of the effects described in this specification or other effects that may be grasped from this specification.

#### BRIEF DESCRIPTION OF DRAWINGS

FIG. 1 is a diagram illustrating a configuration example of a communication system according to an embodiment of the present disclosure.

FIG. 2 is a diagram for describing a transmission acknowledgment in multicast communication of a related art.

FIG. 3 is a diagram illustrating a configuration example of an existing BAR frame.

FIG. 4 is a block diagram illustrating an example of a schematic functional configuration of each of an AP and an STA according to an embodiment of the present disclosure.

FIG. 5 is a diagram for describing an example of allocation of wireless communication resources of an AP according to the present embodiment.

FIG. 6 is a diagram for describing another example of allocation of wireless communication resources of an AP according to the present embodiment.

FIG. 7 is a diagram illustrating a configuration example of a transmission acknowledgment request frame transmitted by an AP according to the present embodiment.

FIG. 8 is a flowchart conceptually illustrating a process of an AP according to the present embodiment.

FIG. 9 is a flowchart conceptually illustrating a process of an STA according to the present embodiment.

FIG. 10 is a diagram for describing an example of allocation of wireless communication resources of an AP according to a first modified example of the present embodiment.

FIG. 11 is a diagram for describing an example of allocation of wireless communication resources of an AP according to a second modified example of the present embodiment.

FIG. 12 is a block diagram illustrating an example of a schematic configuration of a smartphone.

FIG. 13 is a block diagram illustrating an example of a schematic configuration of a car navigation device.

FIG. 14 is a block diagram illustrating an example of a schematic configuration of a wireless access point.

#### MODE(S) FOR CARRYING OUT THE INVENTION

Hereinafter, (a) preferred embodiment(s) of the present disclosure will be described in detail with reference to the appended drawings. In this specification and the appended drawings, structural elements that have substantially the same function and structure are denoted with the same reference numerals, and repeated explanation of these structural elements is omitted.

Further, in this specification and the drawings, there are cases in which a plurality of structural elements having substantially the same function are distinguished by adding different numbers to the end of the same reference numeral. For example, a plurality of structural elements having substantially the same function are distinguished as necessary like an STA 20#1 and an STA 20#2. However, in a case where it is unnecessary to distinguish structural elements having substantially the same function, only the same reference numeral is added. For example, in a case where it is unnecessary to particularly distinguish the STA 20#1 and the STA 20#2, they are simply referred to as "STAs 20."

Note that, the description is given in the following order.

1. Overview of communication device according to embodiment of present disclosure
2. Communication device according to embodiment of present disclosure
  - 2-1. Configuration of device
  - 2-2. Technical feature
  - 2-3. Process performed by device
  - 2-4. Modification
3. Application example
4. Conclusion

#### 1. OVERVIEW OF COMMUNICATION SYSTEM ACCORDING TO EMBODIMENT OF PRESENT DISCLOSURE

First, with reference to FIG. 1, an overview of a communication system according to an embodiment of the present disclosure will be described. FIG. 1 is a diagram illustrating a configuration example of a communication system according to the embodiment of the present disclosure.

The communication system is configured with a communication device 10 and a plurality of communication devices 20. Each of the communication device 10 and the communication device 20 has a wireless communication function. Particularly, the communication device 10 has a multicast communication function of transmitting frames to one or more communication devices. Further, the communication device 10 operates as an access point (hereinafter, also referred to as an "access point (AP)"), and the communication device 20 operates as a station (hereinafter also referred to as a "station (STA)"). Hereinafter, the communication device 10 is also referred to as an "AP 10," and the communication device 20 is also referred to as an "STA 20." For this reason, in the communication system, the multicast communication from the AP 10 to a plurality of STAs 20 can be performed. Further, communication from the AP 10 to the STA 20 is referred to as a "downlink (DL)," and communication from the STA 20 to the AP 10 is also referred to as an "uplink (UL)."

For example, as illustrated in FIG. 1, the communication system may be configured with the AP 10 and a plurality of STAs 20#1 to 20#4. The AP 10 and the STAs 20#1 to 20#4 are connected to each other via wireless communication and perform transmission and reception of frames directly with each other. For example, the AP 10 is a communication device conforming to IEEE 802.11 and transmits a multicast frame having each of the STAs 20#1 to 20#4 as a destination.

Here, the transmission acknowledgment for the multicast frame is considered to be performed in order to improve the reliability of the multicast communication. Specifically, the BAR frame and the BA frame (hereinafter also referred to as a "transmission acknowledgment frame") are exchanged as the transmission acknowledgment for the multicast frame after the multicast frame is transmitted. A transmission acknowledgment in multicast communication of a related art will be described with reference to FIG. 2. FIG. 2 is a diagram for describing a transmission acknowledgment in a multicast communication of a related art.

The wireless communication resources for transmission of the transmission acknowledgment frame for the multicast frame are chronologically allocated to each STA of the transmission acknowledgment target. For example, wireless communication resources for transmission of BAR#1 to

BAR#4 frames and BA#1 to BA#4 frames to STAs #1 to #4 are sequentially allocated along a time axis as illustrated in FIG. 2.

Next, multicast communication of the related art and a communication form for the transmission acknowledgment will be described.

First, after the multicast frame is transmitted to each of the STAs, the AP transmits the BAR frame to each of the STAs in order of time. For example, after the multicast frame is transmitted, the AP transmits the BAR#1 to BAR#4 frames illustrated in FIG. 2 to each of the STAs #1 to #4 in order of time.

Further, each STA transmits the BA frame to the AP when the BAR frame is received. For example, each of STAs #1 to #4 transmits the BA#1 to BA#4 frames illustrated in FIG. 2 to the AP when the BAR#1 to BAR#4 frames are received.

As described above, in the transmission acknowledgment in the multicast communication of the related art, the wireless communication resources for the transmission acknowledgment are chronologically allocated to each of the STAs. For this reason, there are cases in which it is difficult to allocate wireless communication resources to other communication until the transmission acknowledgment for all terminals is completed. Further, the above-mentioned problem is not limited to the multicast communication but may occur similarly even in other communication such as frame multiplex communication in which a frame is transmitted to a plurality of destinations.

Further, in a case in which data for the transmission acknowledgment is smaller in an amount than data transmitted through a frame which is a transmission acknowledgment target, the wireless communication resources may be wasted. The waste of the wireless communication resources in the communication for the transmission acknowledgment will be described in detail with reference to FIG. 3. FIG. 3 is a diagram illustrating a configuration example of an existing BAR frame.

Here, the communication for the transmission acknowledgment is generally performed using substantially the same bandwidth as a bandwidth used for the transmission of the frame which is the transmission acknowledgment target. For example, the BAR frame and the BA frame are transmitted through the same bandwidth as the bandwidth used for transmission of the multicast frame.

On the other hand, the data size of the transmission acknowledgment is often smaller than the data size of the data frame. For example, as illustrated in FIG. 3, the BAR frame includes a physical layer header (PHY Header), a media access control header (MAC Header), BA Control, BA Info, and a frame check sequence (FCS). The data size of the BAR frame is at most 152 octets (bytes) as illustrated in FIG. 3, but the data size of the data frame is usually larger than 152 octets (bytes). For this reason, in this case, an excessive bandwidth is allocated to the communication for the transmission acknowledgment.

In this regard, the present disclosure proposes a communication device which is capable of achieving both an improvement in reliability of communication in which a frame is transmitted to a plurality of destinations and effective use of wireless communication resources. Next, details thereof will be described. Note that, FIG. 1 illustrates the communication system including the AP 10 and the STAs 20 as an example of the communication system. One of the STAs 20 may be a communication device that establishes a plurality of direct links with other STAs 20 instead of the AP 10. In that case, DL can be replaced with “simultaneous transmission from one STA to a plurality of STAs,” and UL

can be replaced with “simultaneous transmission from a plurality of STAs to one STA.”

## 2. COMMUNICATION DEVICE ACCORDING TO EMBODIMENT OF PRESENT DISCLOSURE

As described above, the overview of the communication system according to the embodiment of the present disclosure has been described. Next, the AP 10 and the STAs 20 according to the embodiments of the present disclosure will be described. An example in which the BAR frame and the BA frame are exchanged as a transmission acknowledgment request frame and a transmission acknowledgment response frame will be described below.

### 2-1. Configuration of Device

First, with reference to FIG. 4, a basic functional configuration of each of the AP 10 and the STA 20 according to the embodiment of the present disclosure will be described. FIG. 4 is a block diagram illustrating an example of a schematic functional configuration of each of the AP and the STA 20 according to the embodiment of the present disclosure.

As illustrated in FIG. 4, each of the AP 10 and the STA 20 includes a data processing unit 11, a wireless communication unit 12, a control unit 13, and a storage unit 14.

As a part of a communication unit, the data processing unit 11 performs a process on data for transmission and reception. Specifically, the data processing unit 11 generates a frame on the basis of data from a higher layer of communication, and provides the generated frame to the wireless communication unit 12. For example, the data processing unit 11 generates a frame (or a packet) from the data, and performs a process on the generated frame such as addition of a MAC header for media access control (MAC), addition of an error detection code, or the like. In addition, the data processing unit 11 extracts data from the received frame, and provides the extracted data to the higher layer of communication. For example, the data processing unit 11 acquires data by analyzing a MAC header, detecting and correcting a code error, and performing a reorder process, or the like with regard to the received frame.

The wireless communication unit 12 has a signal processing function, a wireless interface function, and the like as part of a communication unit.

The signal processing function is a function of performing signal processing such as modulation on frames. Specifically, the wireless communication unit 12 performs encoding, interleaving, and modulation on the frame provided from the data processing unit 11 in accordance with a coding and modulation scheme set by the control unit 13, adds a preamble and a PHY header, and generates a symbol stream. Further, the wireless communication unit 12 acquires a frame by performing demodulation, decoding, and the like on the symbol stream obtained by a process of the wireless interface function, and provides the obtained frame to the data processing unit 11 or the control unit 13.

The wireless interface function is a function to transmit/receive a signal via an antenna. Specifically, the wireless communication unit 12 converts a signal related to the symbol stream obtained through the process performed by the signal processing function into an analog signal, amplifies the signal, filters the signal, and up-converts the frequency. Next, the the wireless communication unit 12 transmits the processed signal via the antenna. In addition, on the signal obtained via the antenna, the wireless communication

unit 12 performs a process that is opposite to the process at the time of signal transmission such as down-conversion in frequency or digital signal conversion.

As a part of the communication unit, the control unit 13 controls entire operation of the AP 10 or the STA 20. Specifically, the control unit 13 performs a process such as exchange of information between functions, setting of communication parameters, or scheduling of frames (or packets) in the data processing unit 11.

The storage unit 14 stores information to be used for process to be performed by the data processing unit 11 or the control unit 13. Specifically, the storage unit 14 stores information stored in a transmission frame, information acquired from a receiving frame, information on a communication parameter, or the like.

## 2-2. Technical Feature

Next, characteristic functions of the AP 10 and the STA 20 according to one embodiment of the present disclosure will be described.

((Functions of AP))

First, the characteristic functions of the AP 10 will be described.

(Transmission of Multicast Frame)

The AP 10 transmits the multicast frame to the STA 20. Specifically, the control unit 13 causes the data processing unit 11 to generate a multicast frame whose destination is one or a plurality of STAs 20, and the wireless communication unit 12 transmits the generated multicast frame. For example, the multicast frame may be a data frame. The multicast frame may be a control frame or a management frame.

(Decision of Transmission Acknowledgment Target)

The AP 10 decides the STA 20 which is the transmission acknowledgment target for the multicast frame. Specifically, the control unit 13 decides the number of STAs 20 serving as the transmission acknowledgment target, and selects the decided number or less of STAs 20 as the transmission acknowledgment target from the STAs 20 which are the destination of the multicast frame.

More specifically, the control unit 13 decides the number of STAs 20 serving as the transmission acknowledgment target on the basis of a congestion degree of the communication. For example, the control unit 13 decides the number of STAs 20 serving as the transmission acknowledgment target in accordance with an amount of available wireless communication resources. The control unit 13 may decide the number of the STAs 20 serving as the transmission acknowledgment target on the basis of a predetermined value. For example, the predetermined value is stored in the storage unit 14.

Further, the control unit 13 selects the STA 20 serving as the transmission acknowledgment target from the STAs 20 which are the destination of the multicast frame on the basis of a reception characteristic of the STA 20. For example, the reception characteristic of the STA 20 includes at least one of a symbol error rate, a signal to noise ratio (SN ratio), a communication throughput, and the number of multicast frames successfully received by the STA 20. Then, the control unit 13 preferentially selects the STA 20 having a lower reception characteristic, for example, a lower SN ratio as the transmission acknowledgment target. In this case, since the STA 20 having the communication reliability lower than other STAs 20 is selected as the transmission acknowledgment target, it is possible to effectively improve the reliability of the entire multicast communication.

As described above, the AP 10 decides the number of STAs 20 serving as the transmission acknowledgment target, and selects the decided number or less of STAs 20 as the transmission acknowledgment target from the STAs 20 which are the destination of the multicast frame. Therefore, the radio transmission resources for the transmission acknowledgment are suppressed from being tightened since the number of STAs 20 serving as the destination of the multicast frame is increased. As a result, it is possible to perform the transmission acknowledgment for the multicast frame having the good efficiency.

(Allocation of Wireless Communication Resources for Transmission Acknowledgment)

The AP 10 allocates the wireless communication resources for the transmission acknowledgment to each of the STAs 20 decided as the transmission acknowledgment target. Specifically, the control unit 13 decides a center frequency and a bandwidth used in the transmission acknowledgment response as a transmission frequency for each of the STAs 20 of the transmission acknowledgment target. The allocation of the wireless communication resources will be described in detail with reference to FIGS. 5 and 6. FIG. 5 is a diagram for describing an example of the allocation of the wireless communication resources of the AP 10 according to the present embodiment and FIG. 6 is a diagram for describing another example of the allocation of the wireless communication resources of the AP 10 according to the present embodiment.

The control unit 13 decides the center frequency to be allocated to each of the STAs 20 selected as the destination of the BAR frame transmitted in the same period, that is, the transmission acknowledgment target as the center frequency differing for each STA 20. For example, as illustrated in FIG. 5, the wireless communication resources are allocated to BA#1 to BA#4 frames in the same period, but the center frequencies of the allocated wireless communication resources are different from each other. The center frequencies of the wireless communication resources allocated in different periods may be the same.

Here, the wireless communication resources may be allocated biased to a specific band, depending on a center frequency decision method. Further, there are also cases where the band to which the wireless communication resources are unevenly allocated is crowded. In this case, the communication efficiency in the transmission acknowledgment response may decrease.

In this regard, the AP 10 distributes the band used for the transmission of the transmission acknowledgment response frame to the STAs 20 selected as the transmission acknowledgment target. Specifically, the control unit 13 decides the center frequency on the basis of at least one of identification information of the selected STA 20 and time information of the AP 10.

For example, the identification information is a connection identifier such as an association identifier (AID), and the time information is a time stamp obtained using a time synchronization function (TSF) or the like (hereinafter also referred to as "TSFv"). Then, the control unit 13 decides the center frequency using the following Formula.

[Math. 1]

$$Ch = \text{mod}[(TSFv + AID), CH\_NUM] \quad (1)$$

In Formula (1), Ch indicates an index indicating a channel number, that is, the center frequency, and CH\_NUM indicates the number of channels available for the transmission acknowledgment. The center frequency is uniquely specified

from Ch. Further, since TSFv has a fine grain size, it is desirable that TSFv rounded to the extent that there is no error between AP 10 and STA 20 is used.

The control unit 13 may decide the center frequency to be allocated as a center frequency that is different from the center frequency of the multicast frame. For example, as illustrated in FIG. 5, the center frequency to be allocated to the BA#1 to BA#4 frames is different from the center frequency to be allocated to the multicast frame. Of course, the center frequency of the wireless communication resources for the transmission acknowledgment may be the same as the center frequency allocated to the multicast frame.

Further, the control unit 13 decides a bandwidth allocated to each of the STAs 20 selected as the destination of the BAR frame, that is, the transmission acknowledgment target as a different bandwidth among at least some of the STAs 20. Specifically, the control unit 13 decides a bandwidth of a certain STA 20 on the basis of whether or not a center frequency adjacent to the center frequency allocated to the certain STA 20 is allocated to other STAs 20.

Here, in IEEE 802.11, the BAR frame is supposed to be transmitted through a bandwidth of 20 MHz, that is, one channel. Therefore, when available bandwidths are two or more channels, it is possible to transmit the same BAR frame using the bandwidth of the two or more channels. As a result, in a communication device serving as a reception side, that is, the STA 20, it is desirable to successfully receive at least one of a plurality of BAR frames, and thus a frequency diversity effect is obtained, and it is possible to improve the reliability of the communication for the transmission acknowledgment response.

For example, as illustrated in FIG. 6, since the center frequency adjacent to the center frequency of the BA#2 frame is not allocated to another STA 20, that is, since the transmission acknowledgment for other STAs 20 is not performed using the adjacent center frequency, a wider bandwidth than the bandwidth of the BA#1 frame is allocated to the BA#2 frame. Of course, the same bandwidth may be allocated to each of the STAs 20. For example, as illustrated in FIG. 5, the same bandwidth is allocated to the BA#1 to BA#4 frames.

Further, the bandwidth need not be necessarily expanded even when the adjacent center frequency is not allocated to other STAs 20. For example, as illustrated in FIG. 6, although the center frequency adjacent to the center frequency of the BA#1 frame is empty, the bandwidth of the BA#1 is not expanded.

Further, in addition to the presence or absence of the allocation of the adjacent center frequency to other STAs 20, other conditions may be used for the decision of the bandwidth. For example, the control unit 13 decides the bandwidth on the basis of the presence or absence of allocation of the adjacent center frequency to the other STAs 20 and the reception characteristic of the STA 20.

Further, the control unit 13 may decide a bandwidth used for the transmission of the transmission acknowledgment response frame in the same period as the bandwidth different from the bandwidth of the multicast frame. For example, as illustrated in FIG. 6, a sum of bandwidths allocated to the BA#1 to BA#2 frames transmitted in the same period is narrower than the bandwidth allocated to the multicast frame. Further, a sum of the bandwidths allocated to the BA frames may be the same as the bandwidth allocated to the multicast frame or may be wider than the bandwidth allocated to the multicast frame.

Further, the control unit 13 may decide the bandwidth allocated to each of the STAs 20 as the bandwidth different from the bandwidth of the multicast frame. For example, as illustrated in FIG. 5, the bandwidths allocated to the BA#1 to BA#4 frames are narrower than the bandwidth allocated to the multicast frame. Of course, the bandwidth of the wireless communication resources for the transmission acknowledgment may be the same as the bandwidth allocated to the multicast frame or may be wider than the bandwidth allocated to the multicast frame.

(Transmission of Transmission Acknowledgment Request Frame)

The AP 10 transmits the transmission acknowledgment request frame for the transmission acknowledgment response frame including information specifying the transmission frequency of the transmission acknowledgment response frame (hereinafter also referred to as “frequency allocation information”). Specifically, the control unit 13 causes the data processing unit 11 to generate a BAR frame including the frequency allocation information specifying the transmission frequency of the BA frame for the multicast frame. Then, the wireless communication unit 12 transmits the generated BAR frame. For example, a BAR frame (a Multi-Channel BAR (MBAR)) for the multicast frame illustrated in FIG. 5 is transmitted to each of STAs 20 belonging to a multicast group (for example, a group A) that is the destination of the multicast frame. The MBAR frame according to the present embodiment will be described in detail with reference to FIG. 7. FIG. 7 is a diagram illustrating a configuration example of the MBAR frame transmitted by the AP 10 according to the present embodiment.

First, an overall configuration of the MBAR frame will be described. For example, as illustrated in an upper part of FIG. 7, the MBAR frame includes a PHY Header, a MAC Header, and BAR information of each STA 20 of the transmission acknowledgment target (hereinafter also referred to as simply “BAR information”) and an FCS. A multicast group ID of a transmitted multicast frame is stored in a receiver address (RA) field of the MAC Header serving as the destination information of the MBAR frame. Further, only the STA 20 of the transmission acknowledgment target may be stored as the destination information of the MBAR frame.

Next, the BAR information field for each STA 20 of the transmission acknowledgment target will be described. For example, as illustrated in the upper part of FIG. 7, the BAR information field of each STA 20 of the transmission acknowledgment target includes fields such as STA ID and BA Control each serving as a field in which response device information is stored and Channel Info serving as a field in which the frequency allocation information is stored.

Further, the Channel Info field will be described. For example, as illustrated in a lower part of FIG. 7, the Channel Info field includes fields such as Center Frequency and Channel Width.

Information specifying the center frequency of the transmission frequency for the transmission acknowledgment response frame serving as the frequency allocation information (hereinafter also referred to as “primary channel information”) is stored in the Center Frequency field. For example, the primary channel information is information indicating the center frequency decided for each of the STAs 20 individually.

Information specifying the bandwidth of the transmission frequency for the transmission acknowledgment response frame serving as the frequency allocation information (hereinafter also referred to as “bandwidth information”) is stored

## 11

in the Channel Width field. For example, the bandwidth information is information indicating the bandwidth decided for each of the STAs 20 individually.

The example in which Channel Info is set for each STA 20 of the transmission acknowledgment target has been described, but single Channel Info common to the STAs 20 may be set. Specifically, information related to a calculation formula for calculating the center frequency is stored in the Center Frequency field. For example, the primary channel information includes information indicating Formula (1), information indicating TSFv in Formula (1), and information indicating CH\_NUM. Furthermore, the primary channel information may include only the information indicating TSFv in a case in which Formula (1) and CH\_NUM are known to the STA 20. In this case, the STA 20 calculates the bandwidth of the STA 20 by applying the AID of the STA 20 and TSFv included in the primary channel information to Formula (1). Accordingly, the data amount of the MBAR frame is reduced as compared with the case where the primary channel information of each STA 20 is stored, and it is possible to effectively use the wireless communication resources.

Further, information indicating the maximum bandwidth and the minimum bandwidth among the bandwidths allocated to the selected STAs 20 is stored in the Channel Width field. For example, the STA 20 transmits the BA frame using any one of the minimum bandwidth and the maximum bandwidth stored in the bandwidth information. In this case, the data amount of the MBAR frame is reduced as compared with the case in which the bandwidth information of each STA 20 is stored, and it is possible to effectively use the wireless communication resources.

Further, only one of the Center Frequency field and the Channel Width field may be a field for storing one piece of information common to the STAs 20 of the transmission acknowledgment target described above.

(Reception of Transmission Acknowledgment Response Frame)

The AP 10 receives the transmission acknowledgment response frame which has undergone the frequency division multiplexing on the basis of the frequency allocation information. Specifically, the wireless communication unit 12 receives the BA frame which has undergone the frequency division multiplexing and been transmitted through the transmission frequency specified by the frequency allocation information notified to the STA 20 through the MBAR frame. For example, after the BAR frame is transmitted, the wireless communication unit 12 receives a BA frame group which has undergone the frequency division multiplexing as a response to the BAR frame, and acquires the BA frame of each of the STAs 20 from the BA frame group on the basis of the center frequency and the bandwidth notified to each of the STAs 20 of the transmission acknowledgment target through the BAR frame. The transmission acknowledgment response frame is received only from the STA 20 specified from the response device information included in the transmission acknowledgment request frame.

((Functions of STA))

Next, the characteristic functions of the STA 20 will be described.

(Reception of Multicast Frame)

The STA 20 receives the multicast frame from the AP 10. The control unit 13 sets a communication frequency of the STA 20 to the center frequency and the bandwidth at which the multicast frame is received successfully in advance.

## 12

(Reception of Transmission Acknowledgment Request Frame)

The STA 20 receives the transmission acknowledgment request frame including the frequency allocation information from the AP 10. Specifically, the wireless communication unit 12 receives the MBAR frame from the AP 10 after receiving the multicast frame. If the MBAR frame is received by the wireless communication unit 12, in a case in which the STA 20 belongs to the multicast group which is the destination of the MBAR frame, the data processing unit 11 acquires the BAR information matching the STA ID of the STA 20 from the MBAR frame.

(Setting of Transmission Frequency)

If the transmission acknowledgment request frame including the frequency allocation information is received, the STA 20 sets the transmission frequency of the STA 20 as the transmission frequency for transmitting the transmission acknowledgment response frame. Specifically, the control unit 13 sets the transmission frequency specified from the frequency allocation information included in the BAR information acquired by the data processing unit 11. For example, the control unit 13 sets the transmission frequency of the STA 20 to the center frequency and the bandwidth respectively specified from the primary channel information and the bandwidth information included in the MBAR frame.

In a case in which only information for calculating the center frequency and the bandwidth is included in the MBAR frame as described above, the control unit 13 calculates the center frequency and the bandwidth on the basis of the primary channel information and the bandwidth information.

(Transmission of Transmission Acknowledgment Response Frame)

The STA 20 transmits the transmission acknowledgment response frame for the received transmission acknowledgment request frame on the basis of the frequency allocation information included in the transmission acknowledgment request frame. Specifically, after the MBAR frame is received, the wireless communication unit 12 transmits the BA frame using the transmission frequency specified from the frequency allocation information included in the MBAR frame. For example, in a case in which the BAR information matching the STA ID of the STA 20 is included in the received MBAR frame, the control unit 13 causes the data processing unit 11 to generate the BA frame as the response to the MBAR frame. Then, the wireless communication unit 12 transmits the generated BA frame to the AP 10 through the center frequency and the bandwidth set on the basis of the frequency allocation information included in the acquired BAR information. As a result, the BA frame transmitted from the STA 20 undergoes the frequency division multiplexing, and the BA frame group which has undergone the frequency division multiplexing is received by the AP 10.

## 2-3. Process of Device

Next, a process of the AP 10 and the STA 20 according to the present embodiment will be described.

(Process of AP)

First, the process of the AP 10 according to the present embodiment will be described with reference to FIG. 8. FIG. 8 is a flowchart conceptually illustrating the process of the AP 10 according to the present embodiment.

The AP 10 transmits the multicast frame to each of the STAs 20 (step S102). Specifically, the control unit 13 causes the data processing unit 11 to generate the multicast frame

whose destination is each of the STAs 20. Then, the wireless communication unit 12 transmits the generated multicast frame.

Next, the AP 10 transmits the BAR frame to each of the STAs 20 (step S104). Specifically, the control unit 13 generates the MBAR frame including the frequency allocation information for the STA 20 of the transmission acknowledgment target in which the multicast group of the multicast frame transmitted to the data processing unit 11 is the destination. Then, the wireless communication unit 12 transmits the generated MBAR frame. Further, the MBAR frame may be aggregated with the multicast frame.

Then, the AP 10 configures a reception setting on the basis of the transmission frequency of the BA frame (step S106). Specifically, the control unit 13 causes the wireless communication unit 12 to set a reception frequency so that the BA frame transmitted through the center frequency and the bandwidth specified on the basis of the frequency allocation information included in the MBAR frame is received.

Then, the AP 10 determines whether or not the BA frame is received (step S108). Specifically, after the MBAR frame is transmitted, the control unit 13 determines whether or not the BA frame serving as the response to the MBAR frame is received from each of the STAs 20 of the transmission acknowledgment target. In a case in which the BA frame is determined not to be received from the STA 20 of the transmission acknowledgment target, the control unit 13 causes the wireless communication unit 12 to retransmit the BAR frame or the MBAR frame for the BA frame which is not yet received. In a case in which the BA frame is not received within a predetermined period of time, the process may return to step S102, and the multicast frame or the data frame may be retransmitted to the STA 20 that has not received the BA frame.

(Process of STA)

Next, a process of the STA 20 according to the present embodiment will be described with reference to FIG. 9. FIG. 8 is a flowchart conceptually illustrating the process of the STA 20 according to the present embodiment.

The STA 20 receives the multicast frame from the AP 10 (step S202). Specifically, the wireless communication unit 12 receives the multicast frame from the AP 10.

Then, the STA 20 receives the BAR frame from the AP 10 (step S204). Specifically, the wireless communication unit 12 receives the MBAR frame after receiving the multicast frame. If the MBAR frame is received, the control unit 13 acquires the BAR information matching the STA ID of the STA 20 in a case in which the STA 20 belongs to the multicast group which is the destination of the MBAR frame. In a case in which the STA 20 does not belong to the multicast group or in a case in which there is no BAR information matching the STA ID of the STA 20, the process ends.

If the BAR frame is received, the STA 20 sets a designated transmission frequency as the transmission frequency of the STA 20 (step S206). Specifically, the control unit 13 sets the transmission frequency of the STA 20 on the basis of the primary channel information and the bandwidth information included in the BAR information acquired from the received MBAR frame.

Then, the STA 20 transmits the BA frame to the AP 10 (step S208). Specifically, the control unit 13 causes the data processing unit 11 to generate the BA frame serving as the response to the MBAR frame. Then, the wireless commu-

nication unit 12 transmits the generated BA frame to the AP 10 through the set transmission frequency.

#### 2-4. Conclusion of Embodiment of Present Disclosure

As described above, according to one embodiment of the present disclosure, the AP 10 transmits the transmission acknowledgment request frame for the transmission acknowledgment response frame including the frequency allocation information specifying the transmission frequency of the transmission acknowledgment response frame, and receives the transmission acknowledgment response frame which has undergone the frequency division multiplexing on the basis of the frequency allocation information. Further, the STA 20 receives the transmission acknowledgment request frame and transmits the transmission acknowledgment response frame on the basis of the frequency allocation information. As a result, the transmission acknowledgment response frame undergoes the frequency division multiplexing. Thus, the transmission acknowledgment response related to the communication in which a frame is transmitted to a plurality of destinations is performed using the frequency division multiplex communication, and thus it is possible to effectively use the wireless communication resources while improving the reliability of the communication as compared with the case in which the communication for the transmission acknowledgment response is chronologically performed.

Further, the transmission acknowledgment response frame is transmitted by the STA 20 through the transmission frequency specified from the frequency allocation information. Therefore, the reliability of the transmission acknowledgment response frame being received by the AP 10 can be improved, and the communication efficacy can be improved.

Further, the transmission acknowledgment response frame includes the transmission acknowledgment response frame for the multicast frame. Therefore, it is possible to effectively use the wireless communication resources while improving the reliability of the multicast communication.

Further, the transmission acknowledgment request frame may be concatenated to the frame which is the transmission acknowledgment target. Therefore, since the standby time from the transmission of the multicast frame to the transmission of the transmission acknowledgment request frame is saved, it is possible to reduce the time taken for the transmission acknowledgment, that is, to reduce the wireless communication resources used for the transmission acknowledgment.

The transmission acknowledgment request frame includes the response device information specifying the communication device which is requested to transmit the transmission acknowledgment response frame, and the AP 10 receives the transmission acknowledgment response frame from the communication device specified on the basis of the response device information. Further, in a case in which the STA 20 is the communication device specified from the response device information, the STA 20 transmits the transmission acknowledgment response frame. Therefore, since the transmission acknowledgment response frame is transmitted to only a desired communication device, it is possible to further effectively use the wireless communication resources.

Further, the frequency allocation information includes the information specifying the center frequency of the transmission frequency. Therefore, since the notification of the center frequency is given to the STA 20 through the frame, the AP 10 is able to dynamically allocate the center frequency and

perform the transmission acknowledgment response suitable for a communication environment, the state of the STA 20 or the like.

Further, the center frequency differs for each destination of the transmission acknowledgment request frame transmitted during the same period. Thus, since a collision of frames or interference of signals is prevented in the transmission acknowledgment response performed using the center frequency, it is possible to perform the efficient communication in the transmission acknowledgment response.

Further, the center frequency is specified on the basis of at least one of the identification information for the destination of the transmission acknowledgment request frame and the time information on its own device. Therefore, it is possible to suppress the center frequency from being allocated biased to the congested band.

Further, the frequency allocation information includes the information specifying the bandwidth of the transmission frequency. Therefore, since the notification of the bandwidth is given to the STA 20 through the frame, the AP 10 is able to dynamically allocate the bandwidth and perform the transmission acknowledgment response suitable for the communication environment or the state of the STA 20.

Further, the bandwidth is different between at least some of the destinations of the transmission acknowledgment request frame. Therefore, since the bandwidth suitable for each of the STAs 20 is allocated, it is possible to efficiently use the bandwidth in the transmission acknowledgment response of the STA 20 and improve the communication efficiency.

Further, the center frequency is different from the center frequency of the frame which is the transmission acknowledgment target. Further, the bandwidth used for the transmission of the transmission acknowledgment response frame in the same period is different from the bandwidth of the frame which is the transmission acknowledgment target. Therefore, the degree of freedom for the allocation of the wireless communication resources for the transmission acknowledgment response is increased, and it is possible to improve the efficiency of transmission acknowledgment response.

## 2-5. Modified Examples

One embodiment of the present disclosure has been described above. The present embodiment is not limited to the above example. First and second modified examples of the present embodiment will be described below.

### First Modified Example

As the first modified example of the present embodiment, the transmission acknowledgment response frame may undergo time division. Specifically, the transmission acknowledgment request frame further includes transmission time information specifying a transmission time (transmission timing) of the transmission acknowledgment response frame. For example, a transmission time field in which the transmission time information is stored is included in the Channel Info field of the MBAR frame as illustrated in FIG. 7. For example, the transmission time information may be information indicating a standby time inter frame space (IFS) from reception of the multicast frame or the MBAR frame but may be information indicating the transmission time. A process according to the present modified example will be described in detail with reference to FIG. 10. FIG. 10 is a diagram for describing an example

of allocation of wireless communication resources of the AP 10 in accordance with the first modified example of the present embodiment.

The AP 10 decides the presence or absence of time division of the transmission acknowledgment response frame in accordance with the degree of congestion of the communication of the transmission acknowledgment response frame. Specifically, the AP 10 decides the presence or absence of the time division on the basis of the available bandwidth and the number of STAs 20 of the transmission acknowledgment target. For example, in a case in which the number of STAs 20 that can be allocated to the available bandwidth is equal to or larger than the number of STAs 20 of the transmission acknowledgment target, the control unit 13 decides that the time division multiplexing is performed on the transmission acknowledgment response frame. The presence or absence of the time division multiplexing may be decided on the basis of a comparison between the number of STAs 20 of the transmission acknowledgment target and a predetermined threshold value. Further, in the transmission acknowledgment response frame, a communication order may be decided chronologically instead of multiplexing.

Then, in a case in which the time division multiplexing is performed on the transmission acknowledgment response frame, the AP 10 decides the transmission time information so that the time division multiplexing is performed on the transmission acknowledgment response frame. For example, as illustrated in FIG. 10, the control unit 13 allocates a transmission period subsequent to the transmission of the MBAR frame for the BA#1 and BA#2 frames, and allocates a next transmission period subsequent to the transmission period of the BA#1 and BA#2 frames for the BA#3 and BA#4 frames. Then, the control unit 13 decides the transmission time so that each transmission acknowledgment response frame is transmitted in the transmission period.

Then, the AP 10 transmits the transmission acknowledgment request frame including the frequency allocation information and the transmission period information. For example, the data processing unit 11 generates an MBAR frame in which the decided each transmission time is stored in the BAR information for each STA 20 of the transmission acknowledgment target, that is, the transmission time field of the Channel Info field. Then, the generated MBAR frame is transmitted by the wireless communication unit 12. Further, in a case in which the time division multiplexing is not performed, a transmission acknowledgment request frame in which the transmission time information is not stored in the transmission period field may be transmitted, or a transmission acknowledgment request frame with no transmission period field may be transmitted.

The STA 20 that has received the transmission acknowledgment request frame transmits the transmission acknowledgment response frame in the transmission period allocated to the STA 20. For example, if the MBAR is received, the STAs 20#1 and 20#2 transmit the BA#1 and BA#2 frames at a timing which is temporally adjacent to the transmission of the MBAR frame as illustrated in FIG. 10. Further, after the MBAR is received, the STAs 20#3 and 20#4 transmit the BA#3 and BA#4 frames at a timing which is temporally adjacent to the transmission of the BA#1 and BA#2 frames as illustrated in FIG. 10. As a result, the time division multiplexing is performed on the BA#1 and BA#2 frames and the BA#3 and BA#4 frames.

As described above, according to the first modified example of the present embodiment, the transmission acknowledgment request frame further includes the transmission time information specifying the transmission time

of the transmission acknowledgment response frame, and the transmission acknowledgment response frame is transmitted at the transmission time specified from the transmission time information and undergoes the time division. Therefore, it is possible to set more STAs **20** as the transmission acknowledgment target, and it is possible to improve the reliability of communication such as the multicast communication.

Further, the time division is performed on the transmission acknowledgment request frame on the basis of the congestion degree of the communication of the transmission acknowledgment response frame. Here, if the number of STAs **20** serving as a target of communication such as the multicast communication is increased, the frequency resources for the transmission acknowledgment response are insufficient, and thus the number of STAs **20** in which the transmission acknowledgment is not performed may increase. However, according to the present configuration, using the time division multiplexing in addition to the frequency division multiplexing, the wireless communication resources for the transmission acknowledgment response are additionally secured, and the reliability of the multicast communication can be prevented from being lowered due to the increase in the number of STAs **20**.

#### Second Modified Example

As the second modified example of the present embodiment, the transmission acknowledgment response frame may be a transmission acknowledgment response frame for a multiplexed frame. Specifically, the transmission acknowledgment response frame undergoes the frequency division multiplexing or includes a transmission acknowledgment response frame for a frame which undergoes the space division multiplexing. A process of the present modified example will be described in detail with reference to FIG. **11**. FIG. **11** is a diagram for describing an example of allocation of wireless communication resources of the AP **10** according to the second modified example of the present embodiment.

Instead of transmission of data frames using a multicast method, the AP **10** transmits a frame group which has undergone the space division multiplexing and the frequency division multiplexing to the STA **20**. For example, the AP **10** transmits data frames DATA#**1** to DATA#**4** which have undergone the space division multiplexing and the frequency division multiplexing illustrated in FIG. **11** to each of the STAs **20#1** to **20#4**. Further, only the frequency division multiplexing or the space division multiplexing may be performed on the data frames DATA#**1** to DATA#**4**.

Then, the AP **10** transmits the transmission acknowledgment request frame for the multiplexed frame group to each of the STAs **20** of the transmission acknowledgment target. For example, the AP **10** transmits the MBAR including the BAR information for each of the data frames DATA#**1** to DATA#**4**. Instead of the MBAR frame, the BAR frame group obtained by performing the frequency division multiplexing or the space division multiplexing on the BAR#**1** to BAR#**4** frames for each of the data frames DATA#**1** to DATA#**4** may be transmitted. Further, in this case, each of the data frames and each of the corresponding BAR frames may be connected (aggregated).

Then, the STA **20** which has received the transmission acknowledgment request frame transmits the transmission acknowledgment response frame on the basis of the frequency allocation information included in the transmission acknowledgment request frame. For example, the STAs

**20#1** to **20#4** transmits the BA#**1** to BA#**4** frames, and the BA#**1** to BA#**4** frames are subjected to the frequency division multiplexing. Further, in a case in which the STA **20** supports the space division multiplex communication, the BA frame group may undergo the space division multiplexing.

As described above, according to the second modified example of the present embodiment, the transmission acknowledgment response frame includes the transmission acknowledgment response frame for the frame which has undergone the frequency division multiplexing or the space division multiplexing. Therefore, it is possible to effectively use the wireless communication resources while improving the reliability of communication even for the multiplex communication.

### 3. APPLICATION EXAMPLE

The technology according to the present disclosure can be applied to various products. For example, the communication device **20** (that is, the STA **20**) may be realized as mobile terminals such as smartphones, tablet personal computers (PCs), notebook PCs, portable game terminals, or digital cameras, fixed-type terminals such as television receivers, printers, digital scanners, or network storages, or car-mounted terminals such as car navigation devices. In addition, the STA **20** may be realized as terminals that perform machine to machine (M2M) communication (also referred to as machine type communication (MTC) terminals) such as smart meters, vending machines, remotely controlled monitoring devices, or point of sale (POS) terminals. Furthermore, the STA **20** may be wireless communication modules mounted in such terminals (for example, integrated circuit modules configured by one die).

On the other hand, for example, the communication device **10** (that is, the AP **10**) may be realized as a wireless LAN access point (also referred to as a wireless base station) which has a router function or does not have a router function. The AP **10** may be realized as a mobile wireless LAN router. The AP **10** may also be a wireless communication module (for example, an integrated circuit module configured with one die) mounted on such a device.

#### 3-1. First Application Example

FIG. **12** is a block diagram illustrating an example of a schematic configuration of a smartphone **900** to which the technology of the present disclosure can be applied. The smartphone **900** includes a processor **901**, a memory **902**, a storage **903**, an externally connected interface **904**, a camera **906**, a sensor **907**, a microphone **908**, an input device **909**, a display device **910**, a speaker **911**, a wireless communication interface **913**, an antenna switch **914**, an antenna **915**, a bus **917**, a battery **918**, and an auxiliary controller **919**.

The processor **901** may be, for example, a central processing unit (CPU) or a system on chip (SoC), and controls functions of an application layer and other layers of the smartphone **900**. The memory **902** includes random access memory (RAM) and read only memory (ROM), and stores data and programs executed by the processor **901**. The storage **903** can include a storage medium such as a semiconductor memory or a hard disk. The externally connected interface **904** is an interface for connecting an externally attached device such as a memory card or a universal serial bus (USB) device to the smartphone **900**.

The camera **906** has an image sensor, for example, a charge coupled device (CCD) or a complementary metal

oxide semiconductor (CMOS), to generate captured images. The sensor 907 can include a sensor group including, for example, a positioning sensor, a gyro sensor, a geomagnetic sensor, an acceleration sensor, and the like. The microphone 908 converts sounds input to the smartphone 900 into audio signals. The input device 909 includes, for example, a touch sensor that detects touches on a screen of the display device 910, a key pad, a keyboard, buttons, switches, and the like, to receive operation or information input from a user. The display device 910 has a screen such as a liquid crystal display (LCD), or an organic light emitting diode (OLED) display to display output images of the smartphone 900. The speaker 911 converts audio signals output from the smartphone 900 into sounds.

The wireless communication interface 913 supports one or more wireless LAN standards of IEEE 802.11a, 11b, 11g, 11n, 11ac, and 11ad, to establish wireless communication. The wireless communication interface 913 can communicate with another device via a wireless LAN access point in an infrastructure mode. In addition, the wireless communication interface 913 can directly communicate with another device in a direct communication mode such as an ad hoc mode or Wi-Fi Direct (registered trademark). Note that, Wi-Fi Direct is different from the ad hoc mode. One of two terminals operates as an access point, and communication is performed directly between the terminals. The wireless communication interface 913 can typically include a baseband processor, a radio frequency (RF) circuit, a power amplifier, and the like. The wireless communication interface 913 may be a one-chip module on which a memory that stores a communication control program, a processor that executes the program, and a relevant circuit are integrated. The wireless communication interface 913 may support another kind of wireless communication scheme such as a cellular communication scheme, a near-field communication scheme, or a proximity wireless communication scheme in addition to the wireless LAN scheme. The antenna switch 914 switches a connection destination of the antenna 915 among a plurality of circuits (for example, circuits for different wireless communication schemes) included in the wireless communication interface 913. The antenna 915 has a single or a plurality of antenna elements (for example, a plurality of antenna elements constituting a MIMO antenna), and is used for transmission and reception of wireless signals from the wireless communication interface 913.

Note that the smartphone 900 may include a plurality of antennas (for example, antennas for a wireless LAN or antennas for a proximity wireless communication scheme, or the like), without being limited to the example of FIG. 12. In this case, the antenna switch 914 may be omitted from the configuration of the smartphone 900.

The bus 917 connects the processor 901, the memory 902, the storage 903, the externally connected interface 904, the camera 906, the sensor 907, the microphone 908, the input device 909, the display device 910, the speaker 911, the wireless communication interface 913, and the auxiliary controller 919 with each other. The battery 918 supplies electric power to each of the blocks of the smartphone 900 illustrated in FIG. 13 via power supply lines partially indicated by dashed lines in the drawing. The auxiliary controller 919 causes, for example, necessary minimum functions of the smartphone 900 to be operated in a sleep mode.

The data processing unit 11, the wireless communication unit 12, the control unit 13, and the storage unit 14 described with reference to FIG. 4 may be implemented by the wireless communication interface 913 in the smartphone

900 illustrated in FIG. 12. In addition, at least a part of these functions may be implemented by the processor 901 or the auxiliary controller 919. Further, at least some of the functions may be implemented in the processor 901 or the auxiliary controller 919. For example, when the control unit 13 causes the wireless communication unit 12 to set the transmission frequency on the basis of the frequency allocation information included in the received MBAR frame, it is possible to perform transmission and reception of the transmission acknowledgment response frame using the frequency division multiple access in the communication such as the multicast communication. Accordingly, it is possible to achieve both the improvement in the reliability of communication such as the multicast communication and the effective use of the wireless communication resources.

Note that the smartphone 900 may operate as a wireless access point (software AP) as the processor 901 executes the function of an access point at an application level. In addition, the wireless communication interface 913 may have the function of a wireless access point.

### 3-2. Second Application Example

FIG. 13 is a block diagram illustrating an example of a schematic configuration of a car navigation device 920 to which the technology of the present disclosure can be applied. The car navigation device 920 includes a processor 921, a memory 922, a Global Positioning System (GPS) module 924, a sensor 925, a data interface 926, a content player 927, a storage medium interface 928, an input device 929, a display device 930, a speaker 931, a wireless communication interface 933, an antenna switch 934, an antenna 935, and a battery 938.

The processor 921 may be, for example, a CPU or an SoC controlling a navigation function and other functions of the car navigation device 920. The memory 922 includes RAM and ROM storing data and programs executed by the processor 921.

The GPS module 924 measures a position of the car navigation device 920 (for example, latitude, longitude, and altitude) using GPS signals received from a GPS satellite. The sensor 925 can include a sensor group including, for example, a gyro sensor, a geomagnetic sensor, a barometric sensor, and the like. The data interface 926 is connected with an in-vehicle network 941 via, for example, a terminal (not illustrated) to acquire data generated on the vehicle side such as car speed data.

The content player 927 reproduces content stored in a storage medium (for example, a CD or a DVD) inserted into the storage medium interface 928. The input device 929 includes, for example, a touch sensor that detects touches on a screen of the display device 930, buttons, switches, and the like to receive operation or information input from a user. The display device 930 has a screen such as an LCD or an OLED display to display images of the navigation function or reproduced content. The speaker 931 outputs sounds of the navigation function or reproduced content.

The wireless communication interface 933 supports one or more wireless LAN standards of IEEE 802.11a, 11b, 11g, 11n, 11ac, and 11ad, to execute wireless communication. The wireless communication interface 933 can communicate with another device via a wireless LAN access point in the infrastructure mode. In addition, the wireless communication interface 933 can directly communicate with another device in a direct communication mode such as an ad hoc mode or Wi-Fi Direct. The wireless communication interface 933 can typically have a baseband processor, an RF

circuit, a power amplifier, and the like. The wireless communication interface **933** may be a one-chip module on which a memory that stores a communication control program, a processor that executes the program, and a relevant circuit are integrated. The wireless communication interface **933** may support another kind of wireless communication scheme such as a near-field communication scheme, a proximity wireless communication scheme, or the cellular communication scheme in addition to the wireless LAN scheme. The antenna switch **934** switches a connection destination of the antenna **935** among a plurality of circuits included in the wireless communication interface **933**. The antenna **935** has a single or a plurality of antenna elements and is used for transmission and reception of wireless signals from and to the wireless communication interface **933**.

Note that the car navigation device **920** may include a plurality of antennas, without being limited to the example of FIG. **13**. In this case, the antenna switch **934** may be omitted from the configuration of the car navigation device **920**.

The battery **938** supplies electric power to each of the blocks of the car navigation device **920** illustrated in FIG. **14** via power supply lines partially indicated by dashed lines in the drawing. In addition, the battery **938** accumulates electric power supplied from the vehicle side.

The data processing unit **11**, the wireless communication unit **12**, the control unit **13**, and the storage unit **14** described with reference to FIG. **4** may be implemented by the wireless communication interface **933** in the car navigation device **920** illustrated in FIG. **13**. In addition, at least a part of these functions may be implemented by the processor **921**. Further, at least some of the functions may be implemented in the processor **901** or the auxiliary controller **919**. For example, when the control unit **13** causes the wireless communication unit **12** to set the transmission frequency on the basis of the frequency allocation information included in the received MBAR frame, it is possible to perform transmission and reception of the transmission acknowledgment response frame using the frequency division multiple access in the communication such as the multicast communication. Accordingly, it is possible to achieve both the improvement in the reliability of communication such as the multicast communication and the effective use of the wireless communication resources.

Further, the wireless communication interface **933** may operate as the AP **10** and may provide a wireless connection to a terminal owned by a user riding the vehicle. At this time, for example, when the control unit **13** transmits the MBAR frame through the data processing unit **11** and the wireless communication unit **12**, it is possible to perform transmission and reception of the transmission acknowledgment response frame using the frequency division multiple access in the communication such as the multicast communication. Accordingly, it is possible to achieve both the improvement in the reliability of communication such as the multicast communication and the effective use of the wireless communication resources.

Further, the technology of the present disclosure may be realized as an in-vehicle system (or a vehicle) **940** including one or more blocks of the above-described car navigation device **920**, an in-vehicle network **941**, and a vehicle-side module **942**. The vehicle-side module **942** generates vehicle-side data such as a vehicle speed, the number of

engine rotations, or failure information and outputs the generated data to the in-vehicle network **941**.

### 3-3. Third Application Example

FIG. **14** is a block diagram illustrating an example of a schematic configuration of a wireless access point **950** to which the technology of the present disclosure can be applied. The wireless access point **950** includes a controller **951**, a memory **952**, an input device **954**, a display device **955**, a network interface **957**, a wireless communication interface **963**, an antenna switch **964**, and an antenna **965**.

The controller **951** may be, for example, a CPU or a digital signal processor (DSP) and operates various functions (for example, access limitation, routing, encryption, a fire wall, and log management) of the Internet Protocol (IP) layer and higher layers of the wireless access point **950**. The memory **952** includes RAM and ROM and stores a program executed by the controller **951** and various kinds of control data (for example, a terminal list, a routing table, an encryption key, security settings, and a log).

The input device **954** includes, for example, a button or a switch, and receives operation performed by a user. The display device **955** includes an LED lamp and displays an operation status of the wireless access point **950**.

The network interface **957** is a wired communication interface that connects the wireless access point **950** with a wired communication network **958**. The network interface **957** may include a plurality of connection terminals. The wired communication network **958** may be a LAN such as Ethernet (registered trademark) or may be a wide area network (WAN).

The wireless communication interface **963** supports one or more wireless LAN standards of IEEE 802.11a, 11b, 11g, 11n, 11ac, and 11ad, to supply wireless connection to a nearby terminal as an access point. The wireless communication interface **963** can typically include a baseband processor, an RF circuit, and a power amplifier. The wireless communication interface **963** may be a one-chip module in which memory storing a communication control program, a processor executing the program, and relevant circuits are integrated. The antenna switch **964** switches a connection destination of the antenna **965** among a plurality of circuits included in the wireless communication interface **963**. The antenna **965** includes one antenna element or a plurality of antenna elements and is used to transmit and receive a wireless signal through the wireless communication interface **963**.

The data processing unit **11**, the wireless communication unit **12**, the control unit **13**, and the storage unit **14** described with reference to FIG. **4** may be implemented by the wireless communication interface **963** in the wireless access point **950** illustrated in FIG. **14**. In addition, at least a part of these functions may be implemented by the controller **951**. For example, when the MBAR frame for the multicast frame or the like is transmitted through the data processing unit **11** and the wireless communication unit **12**, it is possible to perform transmission and reception of the transmission acknowledgment response frame using the frequency division multiple access in the communication such as the multicast communication. Accordingly, it is possible to achieve both the improvement in the reliability of communication such as the multicast communication and the effective use of the wireless communication resources.

## 4. CONCLUSION

As described above, according to one embodiment of the present disclosure, the transmission acknowledgment

response related to the communication in which a frame is transmitted to a plurality of destinations is performed using the frequency division multiplex communication, and thus it is possible to effectively use the wireless communication resources as compared with the case in which the communication for the transmission acknowledgment response is chronologically performed while improving the reliability of the communication.

The preferred embodiment(s) of the present disclosure has/have been described above with reference to the accompanying drawings, whilst the present disclosure is not limited to the above examples. A person skilled in the art may find various alterations and modifications within the scope of the appended claims, and it should be understood that they will naturally come under the technical scope of the present disclosure.

For example, in the above embodiment, both the primary channel information and the bandwidth information are included in the transmission acknowledgment request frame, that is, the BAR information, but the present technology is not limited to this example. For example, only the primary channel information may be included in the transmission acknowledgment request frame. For example, in a case in which the bandwidth allocated to the STA 20 is known to the STA 20, only the center frequency field is set in the Channel Info of the MBAR frame, and only the primary channel information is stored. In this case, the data amount of the transmission acknowledgment request frame is reduced to be smaller than the case in which the bandwidth information is included in the transmission acknowledgment request frame, and thus it is possible to reduce the communication amount and effectively use the wireless communication resources.

Similarly, in a case in which the center frequency allocated to the STA 20 is known to the STA 20, only the bandwidth information may be included in the BAR information. Further, in a case in which the transmission time of each STA 20 is known to the STA 20, the transmission acknowledgment request frame not including transmission time information may be transmitted. Further, of course, in a case in which both the center frequency and the bandwidth are known to the STA 20, only the transmission time may be included in the BAR information.

Further, in the above embodiment, the example in which the primary channel information is the information indicating the center frequency or the information for the calculation formula has been described, but the primary channel information may be the information indicating the channel number. In this case, the STA 20 specifies the center frequency from the channel number indicated by the primary channel information.

Further, in the above embodiment, the example in which the BAR information field of the transmission acknowledgment request frame is included in the portion corresponding to the payload has been described, but the BAR information field may be included in the PHY header or the MAC header.

Further, in the above embodiment, the example in which the transmission acknowledgment request frame is transmitted using the multicast scheme or the frame multiplexing scheme has been described, but the transmission acknowledgment request frame may be transmitted as a frame in which the BAR frames addressed to the STAs 20 of the transmission acknowledgment target are aggregated.

Further, in the above embodiment, the example in which the transmission acknowledgment response frame or the transmission acknowledgment request frame undergoes the frequency division multiplexing or the space division mul-

tiplexing has been described, but other frames may undergo the frequency division multiplexing or the space division multiplexing. For example, the BAR frame group and the data frame illustrated in FIG. 11 may undergo the frequency division multiplexing or the space division multiplexing using a frequency or a spatial stream which is empty.

Further, in the above embodiment, for the sake of description, the example in which there is an empty band in FIG. 6 has been described, but it is desirable to allocate the wireless communication resources so that there is no empty band as illustrated in FIG. 5 in order to effectively use the wireless communication resources.

In the above embodiment, the example in which the bandwidth used for the communication in FIGS. 5, 6, 10, and 11 is 80 MHz or 40 MHz has been described, but the bandwidth may be larger or smaller.

Further, the effects described in this specification are merely illustrative or exemplified effects, and are not limitative. That is, with or in the place of the above effects, the technology according to the present disclosure may achieve other effects that are clear to those skilled in the art from the description of this specification.

Additionally, the present technology may also be configured as below.

(1)

A communication device, including:

a communication unit configured to perform communication of a frame,

in which the communication unit

transmits a transmission acknowledgment request frame for a transmission acknowledgment response frame including frequency allocation information specifying a transmission frequency of the transmission acknowledgment response frame, and

receives the transmission acknowledgment response frame which has undergone frequency division multiplexing, on the basis of the frequency allocation information.

(2)

The communication device according to (1),

in which the transmission acknowledgment response frame is transmitted through the transmission frequency specified from the frequency allocation information.

(3)

The communication device according to (1) or (2),

in which the transmission acknowledgment response frame includes a transmission acknowledgment response frame for a multicast frame.

(4)

The communication device according to any one of (1) to (3),

in which the transmission acknowledgment response frame includes a transmission acknowledgment response frame for a frame which has undergone frequency division multiplexing or space division multiplexing.

(5)

The communication device according to any one of (1) to (4),

in which the transmission acknowledgment request frame is connected to a frame which is a transmission acknowledgment target.

(6) The communication device according to any one of (1) to (5),

in which the transmission acknowledgment request frame further includes transmission time information specifying a transmission time of the transmission acknowledgment response frame, and

the communication unit receives the transmission acknowledgment response frame which has undergone time division, on the basis of the transmission time information.

(7) The communication device according to any one of (1) to (6),

in which the transmission acknowledgment request frame includes response device information specifying the communication device which is requested to transmit the transmission acknowledgment response frame, and

the communication unit receives the transmission acknowledgment response frame from the communication device specified on the basis of the response device information.

(8) The communication device according to any one of (1) to (7),

in which the frequency allocation information includes information specifying a center frequency of the transmission frequency.

(9) The communication device according to (8),  
in which the center frequency differs in accordance with respective destinations of the transmission acknowledgment request frame transmitted in a same period.

(10) The communication device according to (8) or (9),  
in which the center frequency is specified on the basis of at least one of identification information for a destination of the transmission acknowledgment request frame and time information of the own device.

(11) The communication device according to any one of (8) to (10),  
in which the center frequency differs from a center frequency of a frame which is a transmission acknowledgment target.

(12) The communication device according to any one of (8) to (11),

in which the frequency allocation information includes information specifying a bandwidth of the transmission frequency.

(13) The communication device according to (12),  
in which the bandwidths are different between at least some of destinations of the transmission acknowledgment request frame.

(14) The communication device according to (12) or (13),  
in which the bandwidth used for transmission of the transmission acknowledgment request frame in a same period is different from a bandwidth of a frame which is a transmission acknowledgment target.

(15) A communication device, including:  
a communication unit configured to perform communication of a frame,

in which the communication unit receives a transmission acknowledgment request frame for a transmission acknowledgment response frame including frequency allocation information specifying a transmission frequency of the transmission acknowledgment response frame, and

transmits the transmission acknowledgment response frame on the basis of the frequency allocation information, and

the transmission acknowledgment response frame undergoes frequency division multiplexing.

(16) The communication device according to (15),  
in which the communication unit transmits the transmission acknowledgment response frame through the transmission frequency specified from the frequency allocation information.

(17) The communication device according to (15) or (16),  
in which the transmission acknowledgment request frame further includes transmission time information specifying a transmission time of the transmission acknowledgment response frame,

the communication unit transmits the transmission acknowledgment response frame at the transmission time specified from the transmission time information, and  
the transmission acknowledgment response frame undergoes time division.

(18) The communication device according to any one of (15) to (17),  
in which the transmission acknowledgment request frame includes response device information specifying the communication device which is requested to transmit the transmission acknowledgment response frame, and

the communication unit transmits the transmission acknowledgment response frame in a case in which the own device is the communication device specified from the response device information.

(19) A communication method, including:  
transmitting, by a communication unit configured to perform communication of a frame, a transmission acknowledgment request frame for a transmission acknowledgment response frame including frequency allocation information specifying a transmission frequency of the transmission acknowledgment response frame; and

receiving the transmission acknowledgment response frame which has undergone frequency division multiplexing, on the basis of the frequency allocation information.

(20) A communication method, including:  
receiving, by a communication unit configured to perform communication of a frame, a transmission acknowledgment request frame for a transmission acknowledgment response frame including frequency allocation information specifying a transmission frequency of the transmission acknowledgment response frame; and

transmitting the transmission acknowledgment response frame on the basis of the frequency allocation information,  
in which the transmission acknowledgment response frame undergoes frequency division multiplexing.

## REFERENCE SIGNS LIST

- 10 communication device, AP  
11 data processing unit  
12 wireless communication unit

- 13 control unit  
 14 storage unit  
 20 communication device, STA

The invention claimed is:

1. A communication device, comprising:

one or more circuits configured to perform communication of a data frame,

wherein the one or more circuits are configured to

transmit, by multicast after the communication of the data frame, a block acknowledgment request (BAR) frame for a block acknowledgment (BA) frame including frequency allocation information specifying a transmission frequency of the BA frame, the BA frame acknowledging the data frame communicated from the communication device, and

receive the BA frame which is frequency division multiplexed, on the basis of the frequency allocation information,

wherein the BAR frame includes a receiver address field storing an identifier of a multicast group specifying destinations of the BAR frame and identification information fields specifying each of one or more destinations of the BAR frame, identification information being association identifiers of the one or more destinations selected from the multicast group, the frequency allocation information being specified for each of the association identifiers, and

wherein the frequency allocation information includes, for each of the association identifiers, information specifying a bandwidth of the transmission frequency.

2. The communication device according to claim 1, wherein the BA frame is transmitted through the transmission frequency specified from the frequency allocation information.

3. The communication device according to claim 1, wherein the BA frame is requested to acknowledge the data frame transmitted by multicast.

4. The communication device according to claim 1, wherein the BA frame is requested to acknowledge the data frame which is frequency division multiplexed or space division multiplexed.

5. The communication device according to claim 1, wherein the BAR frame is aggregated with the data frame communicated from the communication device.

6. The communication device according to claim 1, wherein the BAR frame further includes transmission time information specifying a transmission time of the BA frame, and

the one or more circuits are configured to receive BA frame, which is time division multiplexed, on the basis of the transmission time information.

7. The communication device according to claim 1, wherein the one or more circuits are configured to receive the BA frame from the destination specified on the basis of identification information and the frequency allocation information.

8. The communication device according to claim 1, wherein a center frequency for the transmission frequency differs in accordance with respective destinations of the BAR frame transmitted in a same period.

9. The communication device according to claim 1, wherein a center frequency for the transmission frequency is specified on the basis of at least one of the identification information for a destination of the BAR frame and time information of the communication device.

10. The communication device according to claim 1, wherein a center frequency for the transmission frequency differs from a center frequency of the data frame communicated from the communication device.

11. The communication device according to claim 1, wherein bandwidths are different between at least some of the one or more destinations of the BAR frame.

12. The communication device according to claim 1, wherein a bandwidth used for transmission of the BAR frame in a same period is different from a bandwidth of the data frame.

13. A communication device, comprising: one or more circuits configured to perform communication of a data frame,

wherein the one or more circuits are configured to receive, after the communication of the data frame, a block acknowledgment request (BAR) frame for a block acknowledgment (BA) frame including frequency allocation information specifying a transmission frequency of the BA frame, the BAR frame being multicast, the BA frame acknowledging the data frame, and

transmit the BA frame on the basis of the frequency allocation information, the BA frame being frequency division multiplexed,

wherein the BAR frame includes a receiver address field storing an identifier of a multicast group specifying destinations of the BAR frame and identification information fields specifying each of one or more destinations of the BAR frame, identification information being association identifiers of the one or more destinations selected from the multicast group, the frequency allocation information being specified for each of the association identifiers, and

wherein the frequency allocation information includes, for each of the association identifiers, information specifying a bandwidth of the transmission frequency.

14. The communication device according to claim 13, wherein the one or more circuits are configured to transmit the BA frame through the transmission frequency specified by the frequency allocation information.

15. The communication device according to claim 13, wherein

the BAR frame further includes transmission time information specifying a transmission time of the BA frame, the one or more circuits are further configured to transmit the BA frame at the transmission time specified by the transmission time information, and the BA frame is time division multiplexed.

16. The communication device according to claim 13, wherein the one or more circuits are further configured to transmit the BA frame in a case in which the communication device is specified by the identification information.

17. A communication method, comprising: multicasting, by circuitry configured to perform communication of a data frame before the multicasting, a block acknowledgment request (BAR) frame for a block acknowledgment (BA) frame including frequency allocation information specifying a transmission frequency of the BA frame, the BA frame acknowledging the data frame communicated from the circuitry; and

receiving the BA frame which is frequency division multiplexed on the basis of the frequency allocation information,

wherein the BAR frame includes a receiver address field storing an identifier of a multicast group specifying destinations of the BAR frame and identification infor-

29

mation fields specifying each of one or more destinations of the BAR frame, identification information being association identifiers of the one or more destinations selected from the multicast group, the frequency allocation information being specified for each of the association identifiers, and

wherein the frequency allocation information includes, for each of the association identifiers, information specifying a bandwidth of the transmission frequency.

18. A communication method, comprising:

receiving, with circuitry configured to perform communication of a data frame before the reception, a block acknowledgment request (BAR) or a block acknowledgment (BA) frame including frequency allocation information specifying a transmission frequency of the BA frame, the BAR frame being multicast, the BA frame acknowledging the data frame communicated to the circuitry; and

30

transmitting the BA frame on the basis of the frequency allocation information, the BA frame frequency division multiplexed,

wherein the BAR frame includes a receiver address field storing an identifier of a multicast group specifying destinations of the BAR frame and identification information fields specifying each of one or more destinations of the BAR frame, identification information being association identifiers of the one or more destinations selected from the multicast group, the frequency allocation information being specified for each of the association identifiers, and

wherein the frequency allocation information includes, for each of the association identifiers, information specifying a bandwidth of the transmission frequency.
