(57) **ABSTRACT**

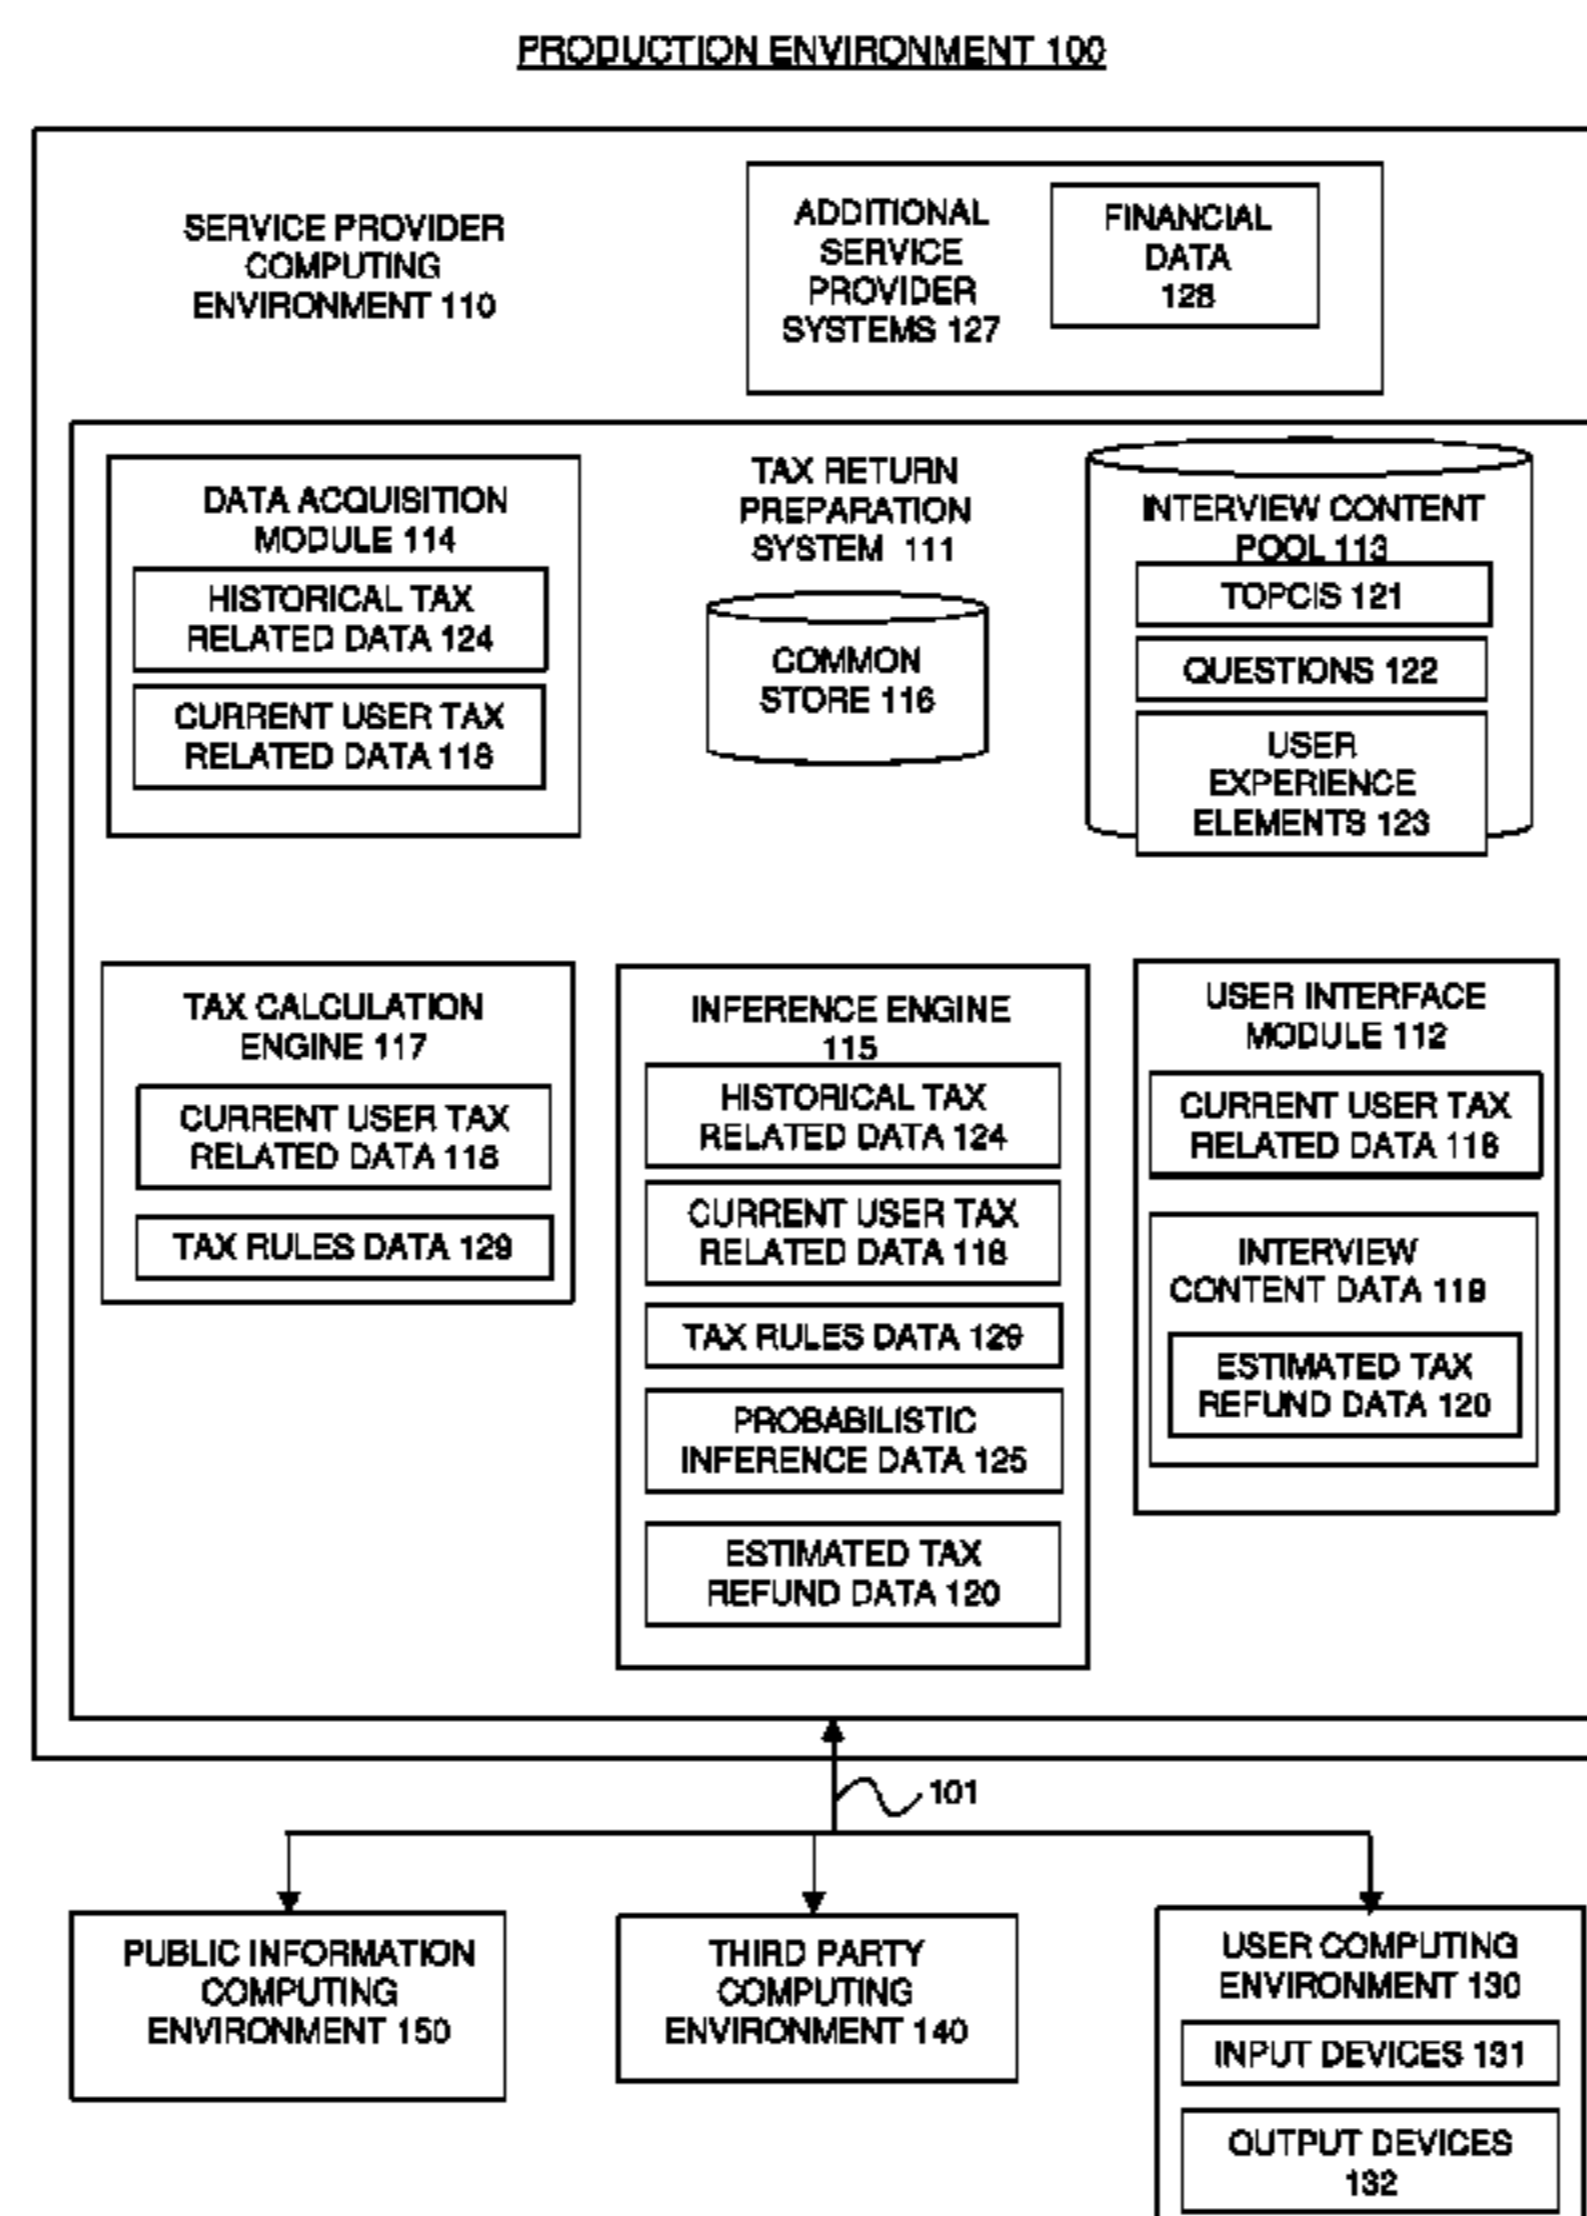

A method and system provide estimated tax refund data to a user of a tax return preparation system throughout personalized tax return preparation interview. The method and system receive current user tax related data associated with the user, retrieve tax rules data, and gather historical tax related data associated with historical users of the tax return preparation system. The method and system further generate probabilistic inference data including inferences about tax related characteristics of the user based on the historical tax related data and the tax rules data. The method and system provide estimated tax refund data to the user based on the probabilistic inference data.

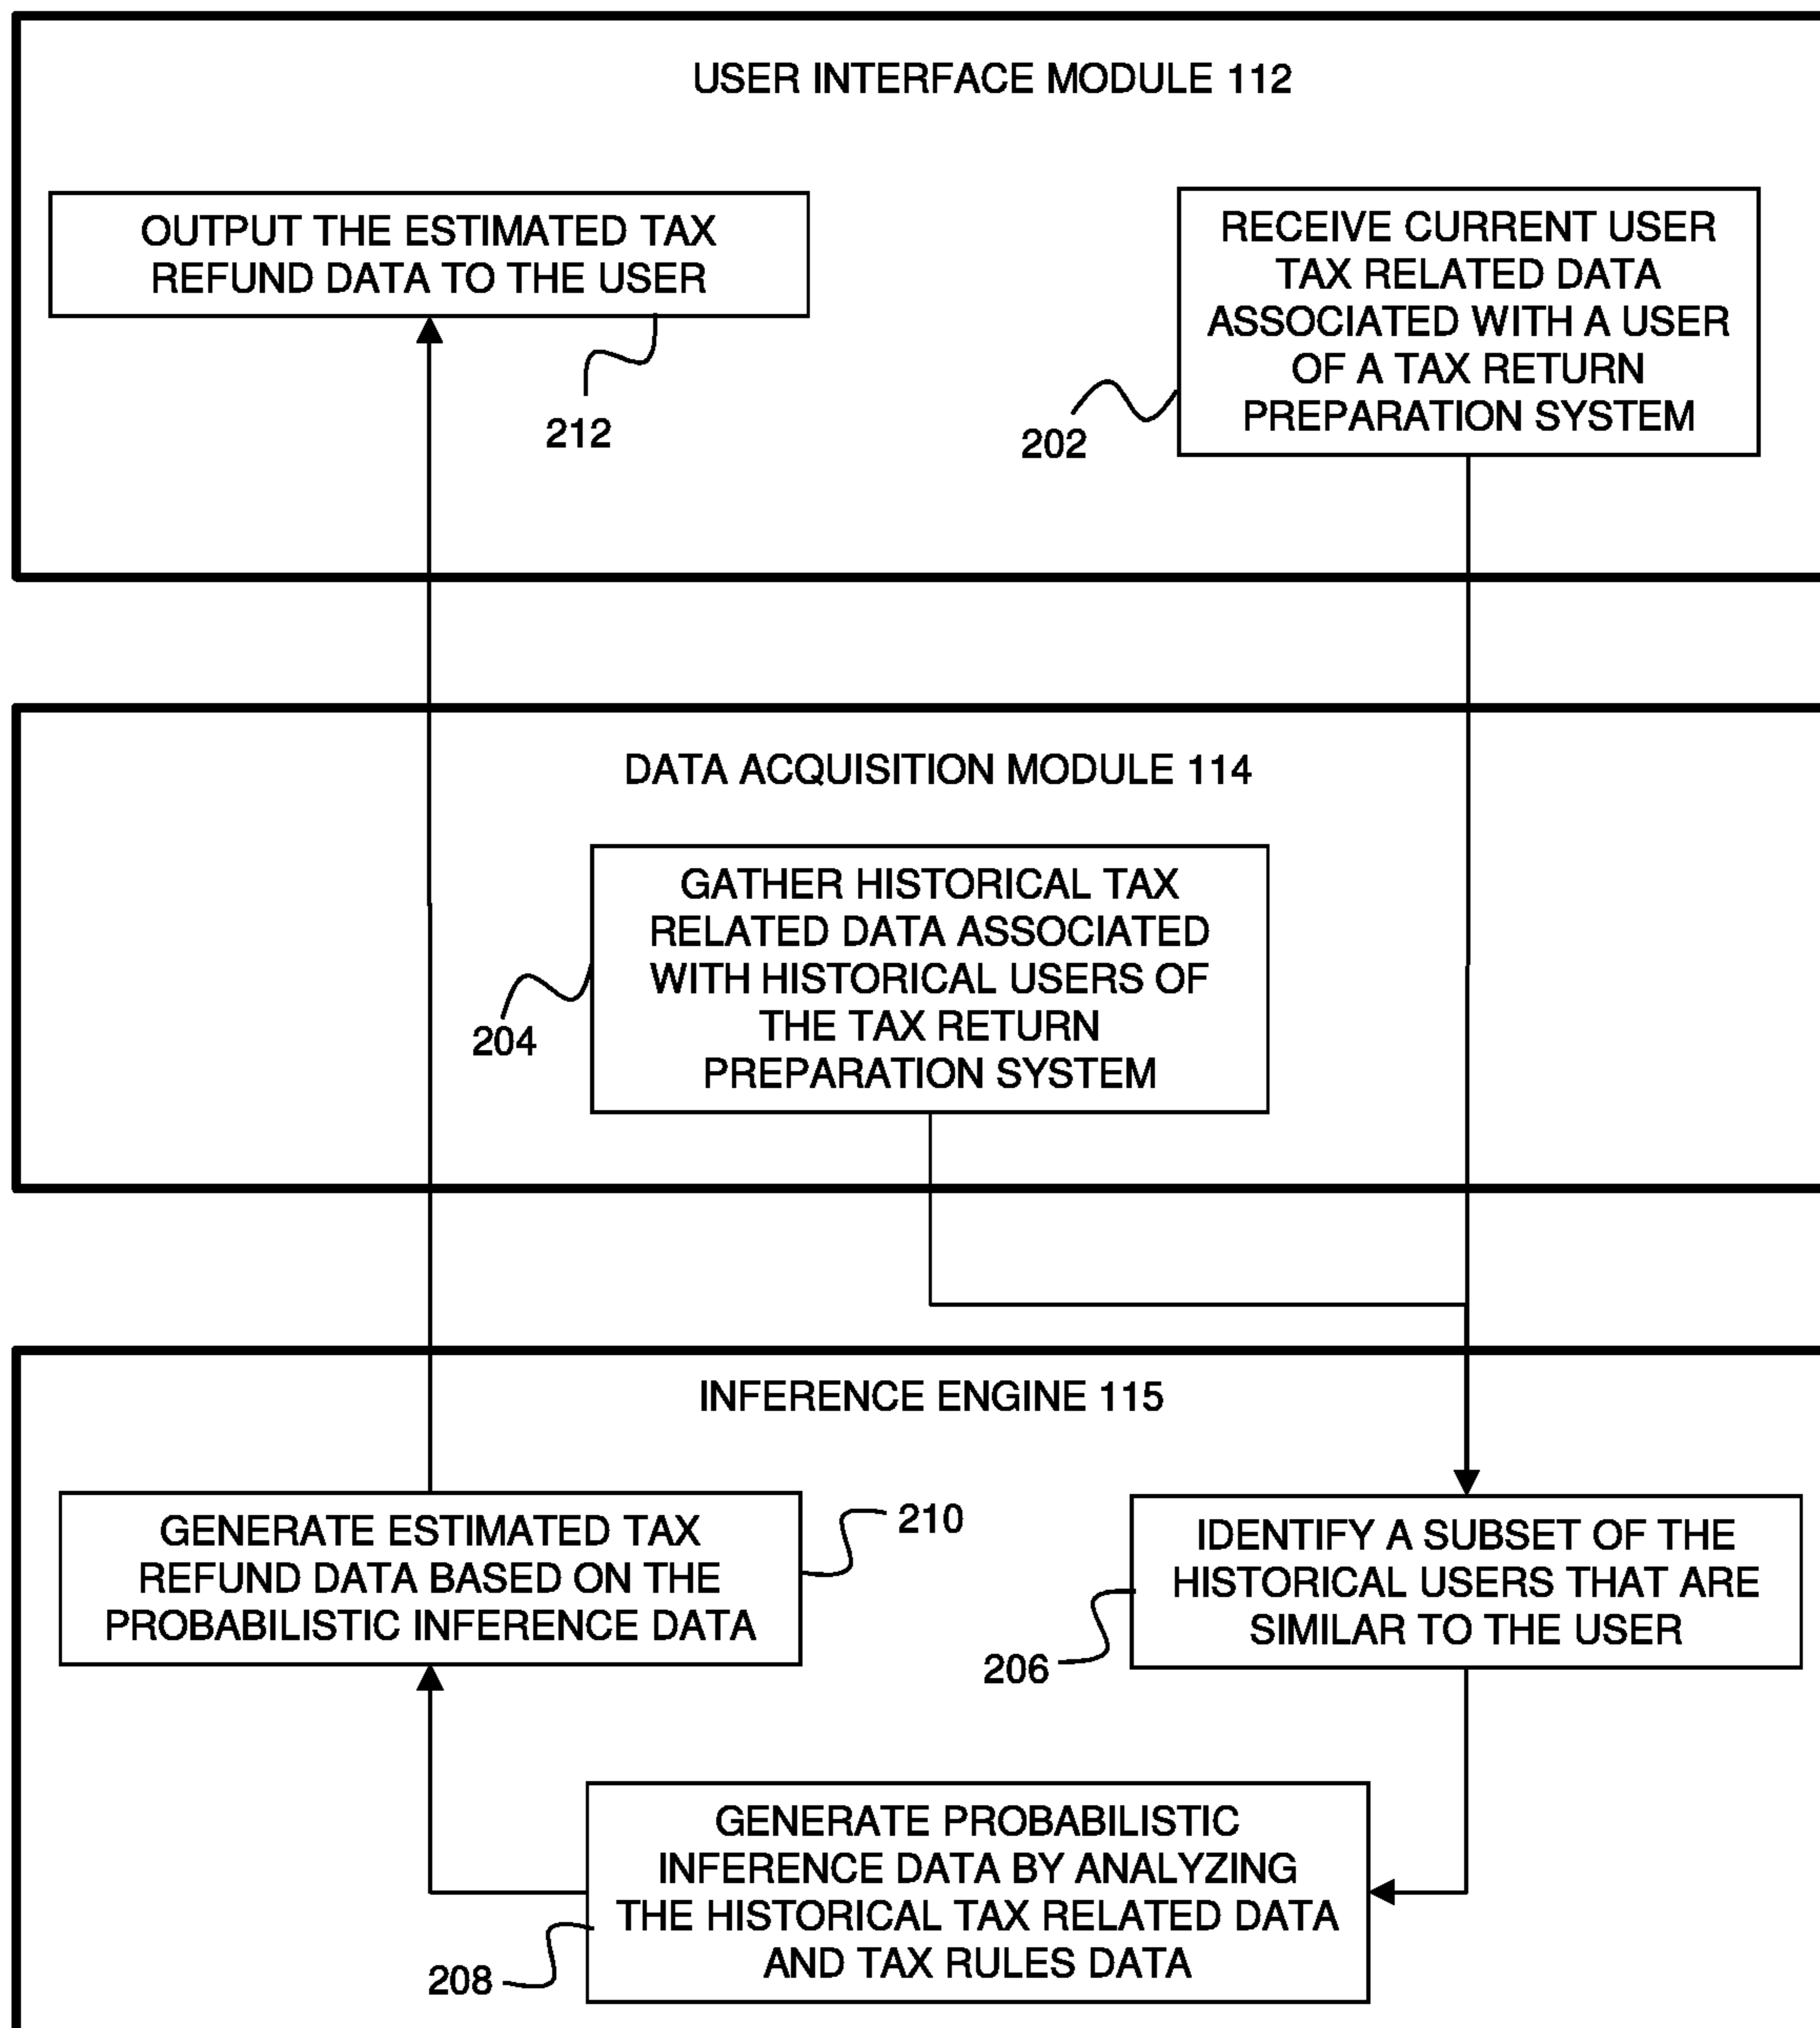

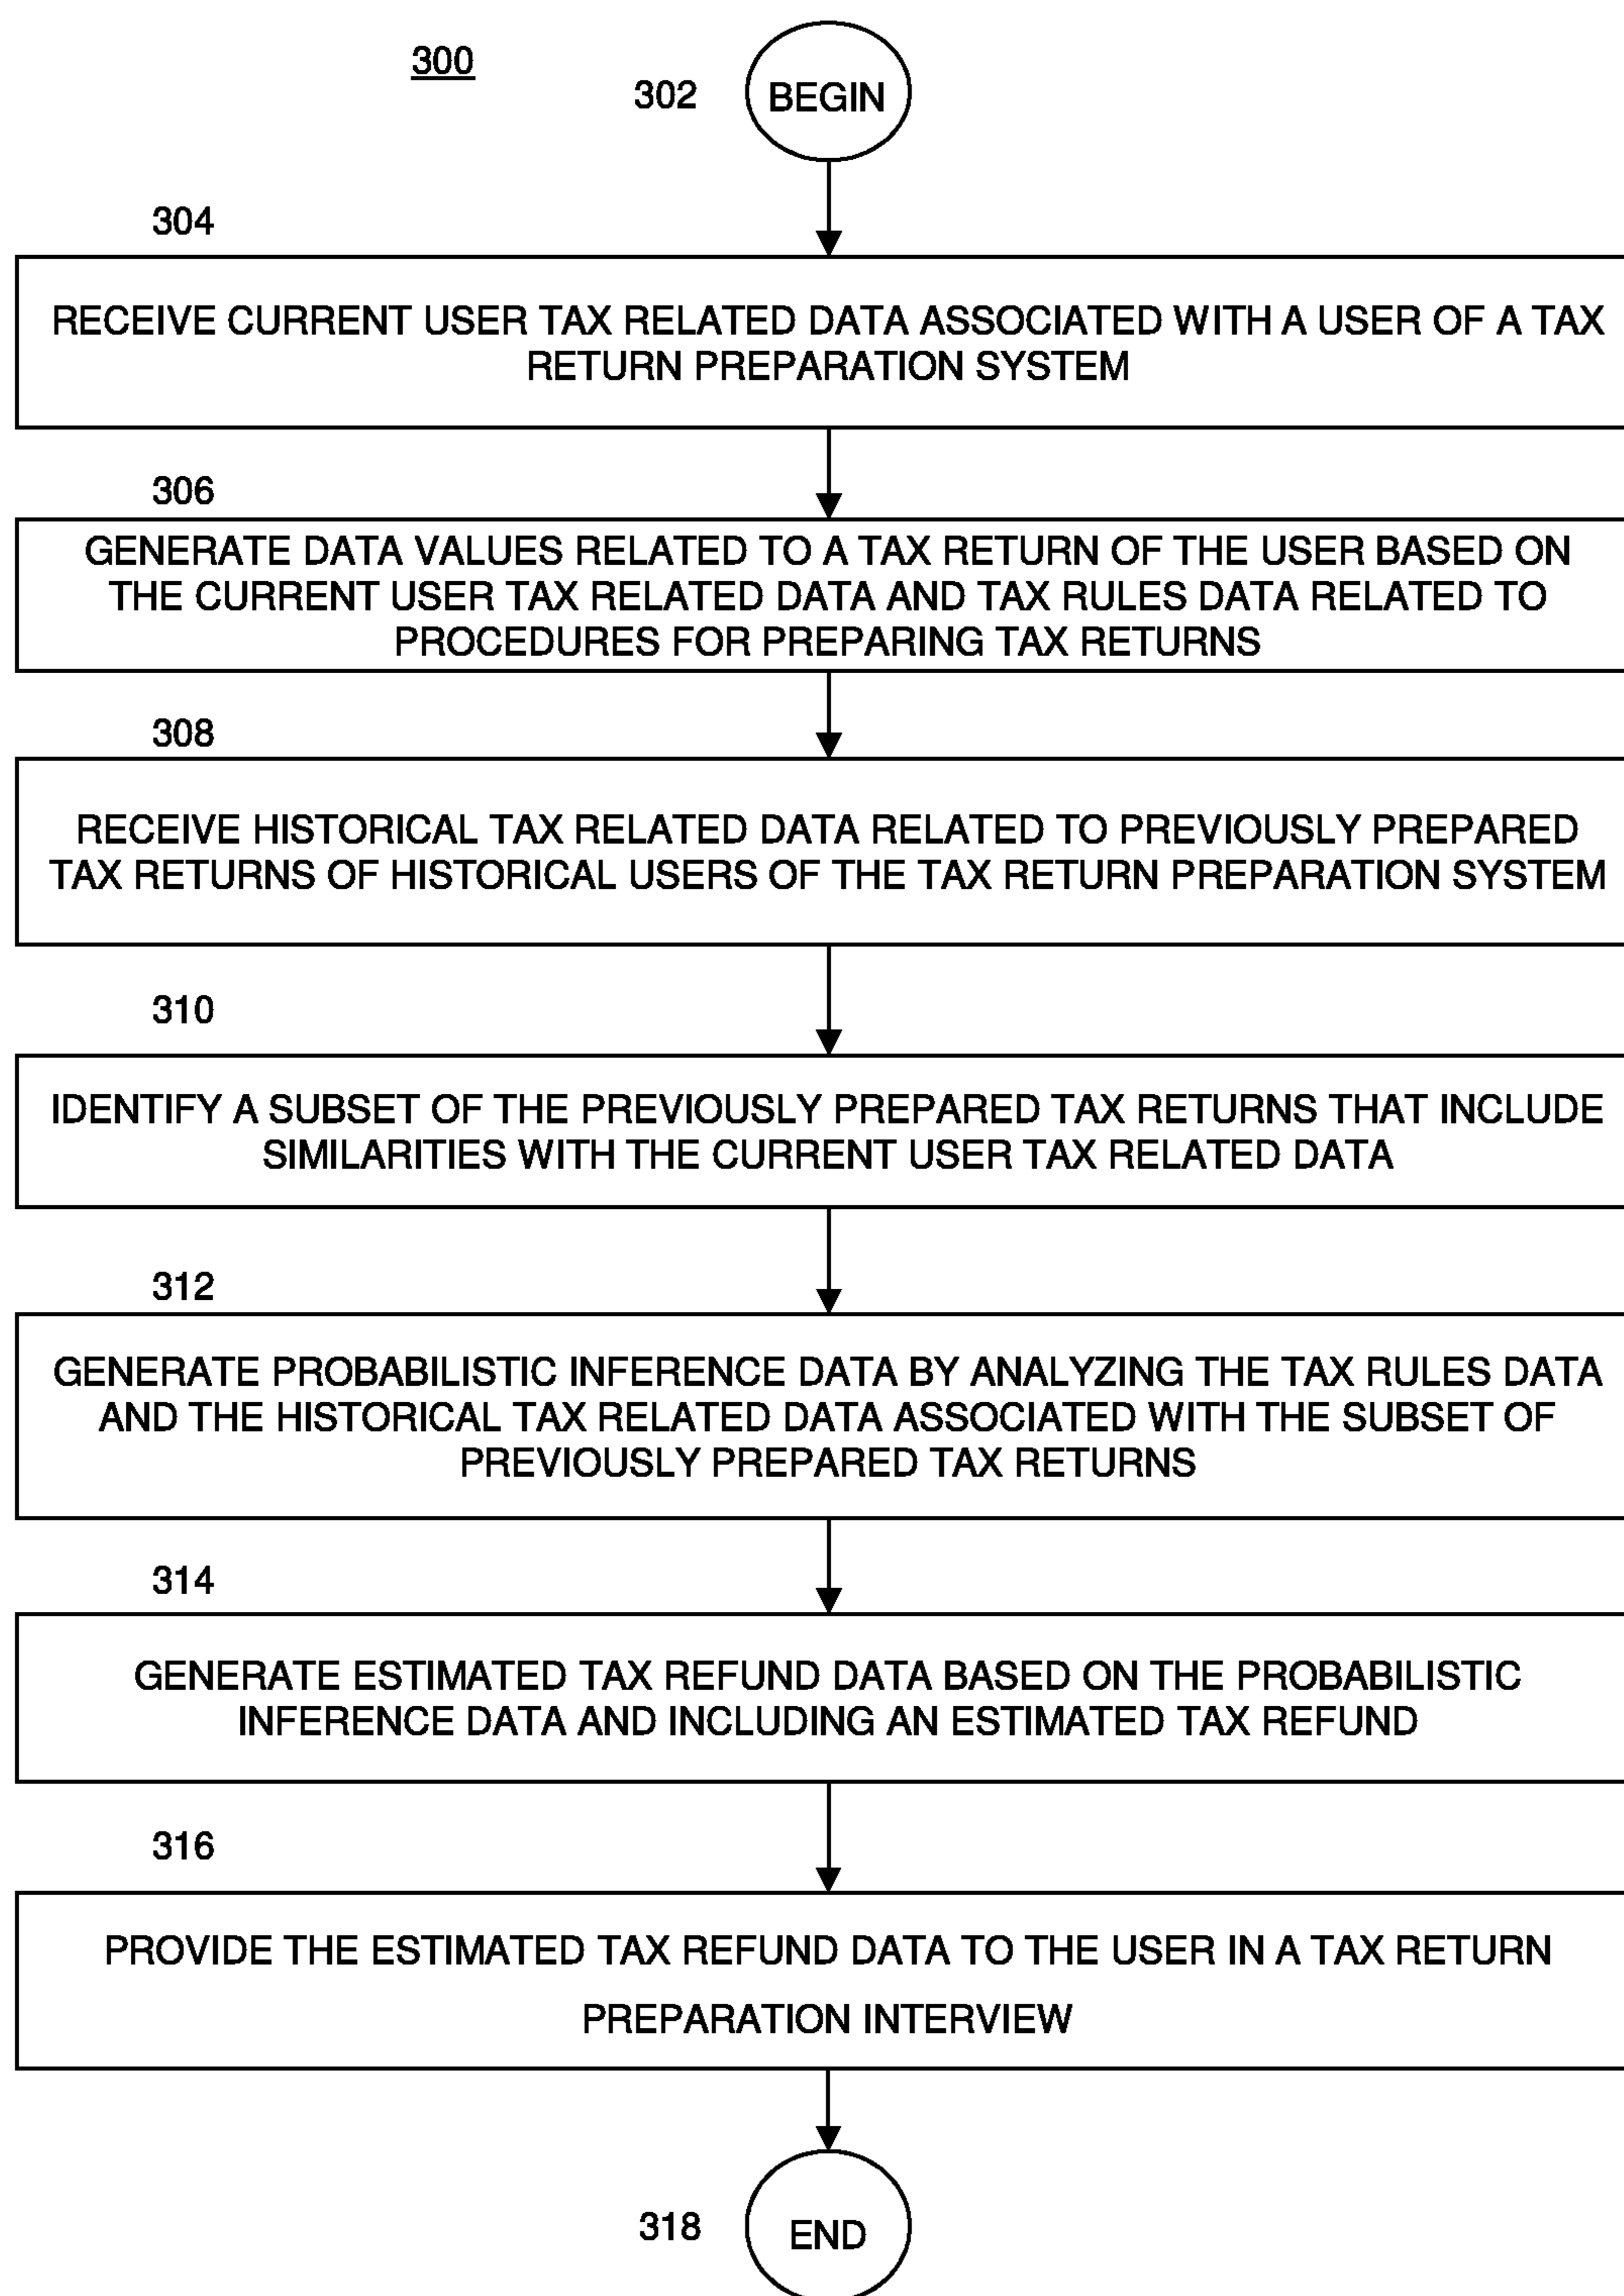

FIG. 2

**FIG. 3**

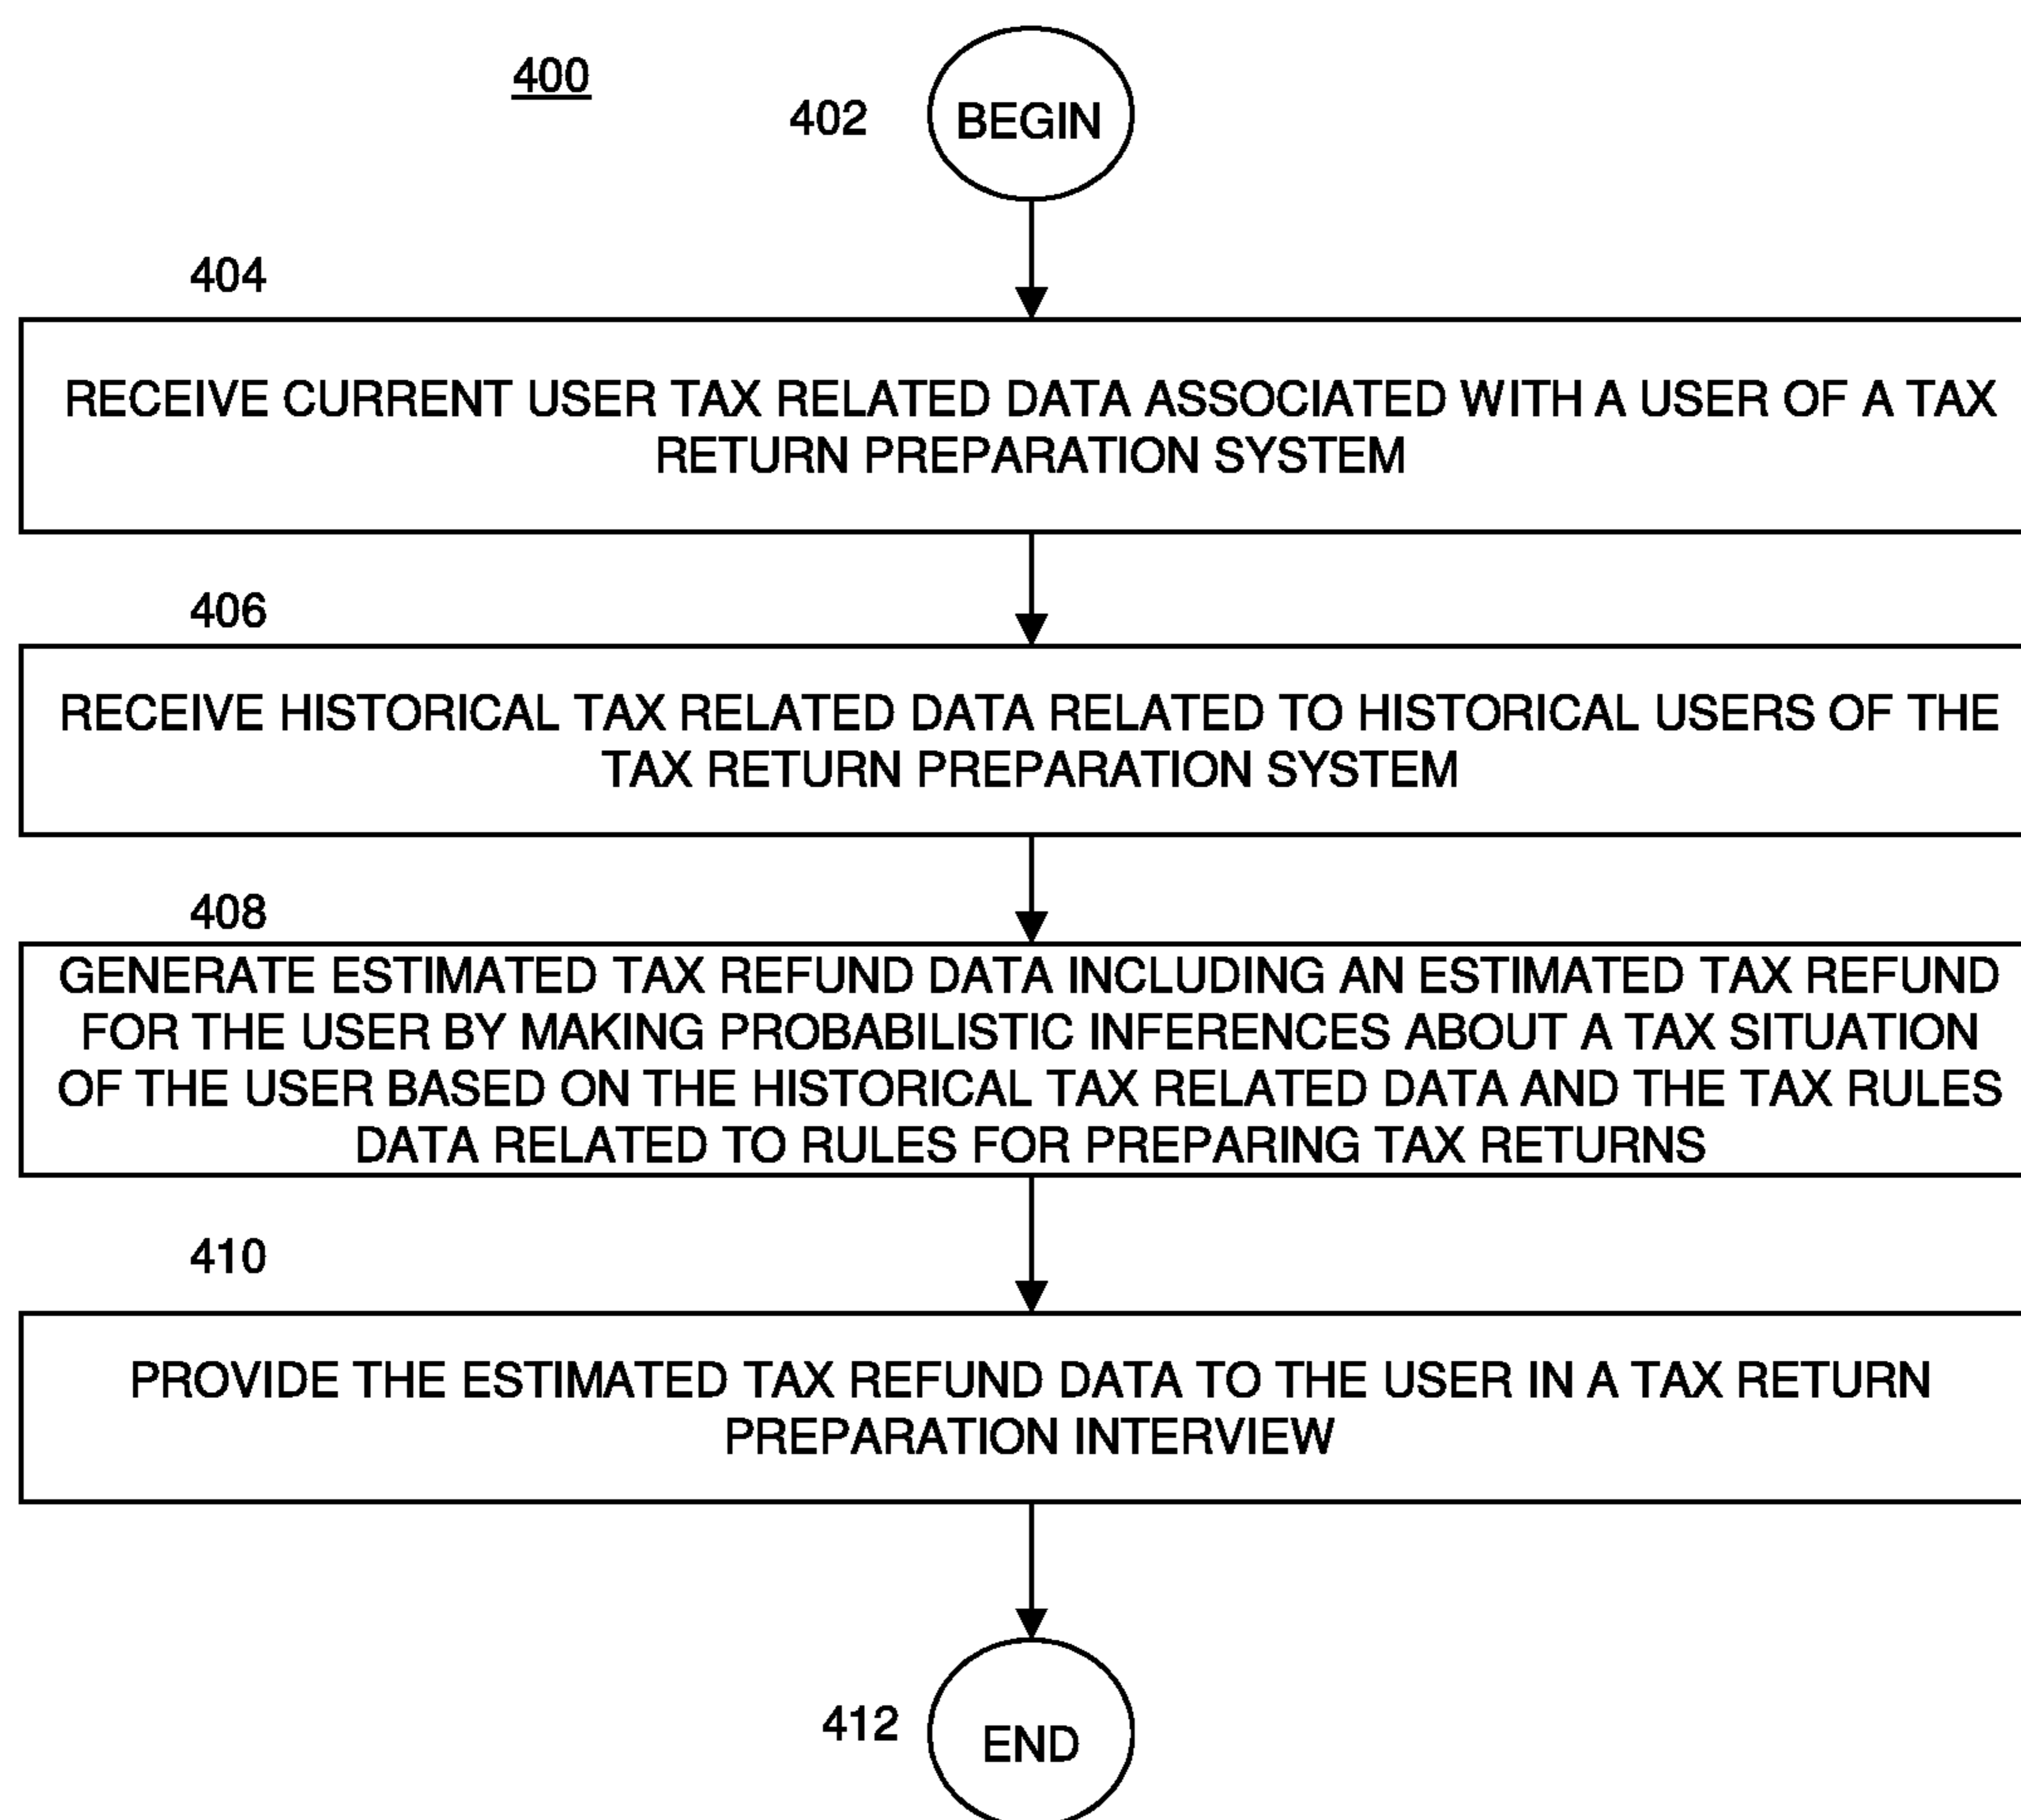

FIG. 4

**SYSTEM AND METHOD FOR PROVIDING A
PREDICTED TAX REFUND RANGE BASED
ON PROBABILISTIC CALCULATION**

BACKGROUND

Federal and State Tax law has become so complex that it is now estimated that each year Americans alone use over 6 billion person hours, and spend nearly 4 billion dollars, in an effort to comply with Federal and State Tax statutes. Given this level of complexity and cost, it is not surprising that more and more taxpayers find it necessary to obtain help, in one form or another, to prepare their taxes. Tax return preparation systems, such as tax return preparation software programs and applications, represent a highly accessible and affordable source of tax preparation assistance. However, traditional tax return preparation systems are typically static and inflexible and provide a tax return preparation process that is the same for each user.

For example, some traditional tax return preparation systems provide an estimated tax refund to the user during the tax return preparation interview. As the user enters data during the tax return preparation interview, the estimated tax refund can undergo large changes. The estimated tax refund may initially be large, before being changed to a large tax liability as further data is entered by the user. These large changes throughout the tax return preparation interview can be confusing and discouraging to the user. Additionally, if the user is expecting a large tax refund, but the initial estimated tax refund at the beginning of the tax return preparation interview indicates an expected tax liability, or a smaller than expected refund, then the user can lose confidence in the tax return preparation system at the beginning of the tax return preparation process. Such problems may cause the user to lose faith in the traditional tax return preparation system and cause the user to decide to forgo the use of the traditional tax return preparation system in favor of other tax return preparation options.

Consequently, there is a long standing technical problem in the tax return preparation system arts in the form of a need to provide personalized electronic financial management services to users.

SUMMARY

Embodiments of the present disclosure provide technical solutions to problems associated with traditional electronic tax return preparation systems by providing methods and systems for combining tax rules with probability based inferences to present an estimated tax refund to a user during a tax return preparation interview. Embodiments of the present disclosure combine rules-based tax return preparation techniques with probabilistic inferences in order to present estimated tax refund data to a user during a tax return preparation interview. Embodiments of the present disclosure can provide the estimated tax refund data to the user even at early stages of the tax return preparation interview when the user has provided only a small amount of data. Embodiments of the present disclosure leverage the fact that a large number of historical users have undergone tax return preparation interviews and that there exists a large amount of data related to these historical users. Embodiments of the present disclosure analyze tax rules data and the historical financial data related to these historical users in order to make probabilistic inferences about the current user in order to generate an estimated tax refund that is likely to be accurate even at early stages of the tax return preparation

interview. A tax return preparation system in accordance with principles of the present disclosure overcomes many of the drawbacks of previous tax return preparation systems by presenting an estimated tax refund that is unlikely to undergo large swings as the user continues to provide data during the tax return preparation interview process. Therefore, the disclosed embodiments provide one or more technical solutions to the technical problem of electronic tax return preparation systems that do not provide a stable and accurate tax refund estimate throughout a tax return preparation interview.

In one embodiment, the tax return preparation system gathers current user tax related data from a user of the tax return preparation system during a tax return preparation interview. The current user tax related data can include data such as an age of the user, a gender of the user, an address of the user, an income of the user, employment data related to the user, tax withholding data, and other tax related information associated with the user. The tax return preparation system also gathers historical tax related data associated with historical users of the tax return preparation system. The tax return preparation system analyzes the current user tax related data and the historical tax related data in order to identify subsets of the historical users that have characteristics that are similar to the characteristics of the user as represented in the current user tax related data collected so far. The tax return preparation system can then make probability based inferences about characteristics of the user that have not yet been provided by the user. Based on these probabilistic inferences, the tax return preparation system can generate estimated tax refund data that includes a range or distribution into which the user's final tax refund amount is likely to fall.

In one embodiment, the tax rules data can include tax rules data associated with rules and procedures for electronically preparing tax returns. The tax return preparation system analyzes the tax rules data, the current user tax related data, and the historical tax returns of the historical users in order to make probabilistic inferences with regards to the data points not yet provided by the user. The tax return preparation system presents an estimated tax refund range that is unlikely to change greatly even though the user is only at the beginning of the tax return preparation interview and only a small portion of the user's tax related data has been provided to the tax return preparation system.

In one embodiment, the tax rules data can include external tax rules data. The external tax rules data can include data related to tax laws, electronic versions of tax forms, electronic versions of tax worksheets, or other data. The external tax data can be obtained from government sources or other third party sources.

In one embodiment, the tax rules data can include internal tax rules data generated and used by the tax return preparation system in order to make sense of and to make use of the external tax rules data. The internal tax rules data can include internally generated forms and worksheets. The internal tax rules data can include data related to sets of procedures, steps, and calculations relevant to the preparation of tax returns for the practically innumerable different financial circumstances of individuals and organizations that prepare tax returns. The tax rules data can include internal tax preparation data utilized by the tax return preparation system in assisting users to electronically prepare their tax returns. The tax return preparation system includes a large database of knowledge for making use of the tax laws, tax forms, and tax worksheets in assisting users to electronically prepare their tax returns. For example, the internal tax rules

3

data includes data relating to the various internal procedures for making use of the government tax forms and for calculating correct data entries for the various lines in the various tax forms. The internal tax rules data includes data related to each line of each tax form and each worksheet. The internal tax rules data indicates the dependencies for calculating or otherwise providing data entries for each line of each tax form. During a tax return preparation interview, the tax return preparation system asks the user for certain kinds of data and then populates the various lines of the tax forms based on the user's data and the tax rules data.

In one embodiment, the tax return preparation interview uses the tax rules data, the current user tax related data that has been provided by or obtained from the user, and the historical tax related data related to previous users of the tax return preparation system in order to make probabilistic inferences regarding data that has not yet been provided by the user. For example, a government tax form may include text related to line 5 of the tax form stating "This value is the lesser of \$6000 and the sum of line 3 and line 4." The tax rules data includes a specific function for generating the correct value for line 5. However, during a tax return preparation interview, the user may not yet have provided the data related to line 4. The tax return preparation system can make a probabilistic inference in order to generate a likely value or range of values for line 5 for the user even though the user has not yet provided the value for line 4. In particular, the tax return preparation system analyzes the tax rules data and identifies the various dependencies for generating the correct value for line 5 and identifies that the value for line 4 is needed. The tax return preparation system accesses historical tax related data, identifies historical users that are similar to the current user, retrieves the values for line 4 related to the historical users, and makes a probabilistic inference as to the likely value of line 5 for the user based on the values for line 4 related to the historical users. The tax return preparation interview can utilize many such inferences in generating an estimated tax refund. In this way, the tax return preparation system can utilize tax rules data, historical tax related data, and current user tax related data in order to make probabilistic inferences about the user and to generate an estimated tax refund for the user.

Principles of the present disclosure can be extended to financial management systems other than tax return preparation systems. In one embodiment, principles of the present disclosure can be utilized by a financial management system that assists users in preparing or managing one or more of investments, banking, loans, retirement plans, credit cards, budgeting, or other financial matters. The financial management system can assist the user in preparing financial documents related to one or more financial matters. The financial management system can utilize financial rules data including external financial rules data such as financial laws, financial forms, financial worksheets, etc. The financial rules data can include internal financial rules data related to procedures for filling out the financial forms or worksheets. The financial management system can utilize the financial rules data in making probabilistic inferences about a current user of the financial return preparation system in order to better provide financial management services to the user.

In one embodiment, the tax return preparation system generates the estimated tax refund data based on the tax refunds of historical users as indicated by the historical tax related data. The tax return preparation engine can identify a subset of the historical users having characteristics similar to those of the current user. The tax return preparation engine can identify a range into which the tax refunds from the

4

historical tax returns fall. Tax return preparation engine can further calculate a range into which the tax refund of the user is most likely to fall. The tax return preparation engine can provide to the user estimated tax refund data that includes a range into which the tax refund of the user is likely to fall. As the user enters further data, the tax return preparation engine refines the estimated tax refund data based on the newly entered data of the user and based on a refined subset of historical users that share characteristics similar to the user.

In one embodiment, the tax return preparation engine generates the estimated tax refund data based on data values in the various data fields of the historical tax returns of those historical users who share characteristics with the current user. The tax return preparation engine can generate probabilistic estimates of data values of the various data fields of the user's tax return for which the user has not yet provided sufficient data for the calculation to be made based purely on the user's data and the tax rules data alone. The tax return preparation engine can calculate or refine the estimated tax refund based on the estimated data values in the various data fields.

In one embodiment, the tax return preparation system includes a user interface module that receives current user tax related data from the user as part of a tax return preparation interview. In one embodiment, the tax return preparation system includes a data acquisition module that gathers historical tax related data associated with historical users of the tax return preparation system. In one embodiment, the tax return preparation system also includes an inference engine that generates probabilistic inferences based on the current user tax related data and the historical tax related data and generates probabilistic inference data including one or more inferences about a financial the user. In one embodiment, the tax return preparation system generates personalized financial interview content based on the probabilistic inference data, including an estimated tax refund. The user interface module then provides an electronic personalized tax return preparation interview to the user and presents the estimated tax refund to the user. The interface module can also adjust other aspects of the tax return preparation interview based on the probabilistic inference data.

In one embodiment, the inference engine can analyze the current user tax related data and the historical tax related data according to one or more algorithms or analysis techniques. For example, in one embodiment, the inference engine can generate probabilistic inference data based on z-scores computed from the historical tax related data. The inference engine can utilize a logistic function to generate the probabilistic inference data. In one embodiment the inference engine may generate probabilistic inference data based on distribution of tax refunds associated with historical tax related data. The inference engine may generate probabilistic inference data based on Monte Carlo integration.

In one embodiment, the data acquisition module gathers historical tax related data or other financial or personal data from one or more government databases, third-party databases, social media databases, or other databases. The inference engine generates the probabilistic inference data based on the current user tax related data and the other financial or personal data.

The disclosed embodiments provide one or more technical solutions to the technical problem of deficiencies in tax return preparation systems by utilizing statistical probabilistic inferences to provide estimated tax refund data to the

user. These and other embodiments of the tax return preparation system are discussed in further detail below.

Providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data is a technical solution to a long standing technical problem and is not an abstract idea for at least a few reasons. First, providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data is not an abstract idea because it is not merely an idea itself (e.g., can be performed mentally or using pen and paper). Second, providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data is not an abstract idea because it is not a fundamental economic practice (e.g., is not merely creating a contractual relationship, hedging, mitigating a settlement risk, etc.). Third, providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data is not an abstract idea because it is not a method of organizing human activity (e.g., managing a game of bingo). Fourth, although mathematics may be used to generate an analytics model, the disclosed and claimed methods and systems of providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data are not an abstract idea because the methods and systems are not simply a mathematical relationship/formula.

Providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data is not an abstract idea because providing more reliable tax refund data allows for significant improvement to the technical fields of user experience, customer service, customer retention, and electronic financial management, according to one embodiment. The present disclosure adds significantly to the field of electronic tax return preparation because the disclosed tax return preparation system: increases the likelihood that a user will not be shown an estimated tax refund that varies wildly throughout the tax return preparation interview; increases the likelihood that inadvertent data entry errors made by the user will be immediately noticed and brought to the attention of the user, increases the likelihood of improving/maintaining a user's trust in the tax return preparation system; and reduces the amount of time users spend in a tax return preparation interview, according to one embodiment.

As a result, embodiments of the present disclosure allow for reduced use of processor cycles, memory, and power consumption, by reducing the time spent by users sifting through various tax topics, entering data, and searching for answers among help topics due to an unnecessarily confusing tax return preparation interview process. Consequently, computing and communication systems implementing or providing the embodiments of the present disclosure are transformed into more operationally efficient devices and systems.

In addition to improving overall computing performance, providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data significantly improves the field of tax return preparation systems, by reducing the amount of time it takes to progress a user through a tax return preparation interview, according to one embodiment. Therefore, both human and non-human resources are utilized more efficiently. Furthermore, by providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data, loyalty in the tax return preparation system with which the tax return preparation system is

associated, which results in repeat customers, efficient tax return preparation interviews such as tax return preparation interviews, and reduced abandonment of use of the tax return preparation system, according to one embodiment.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram of software architecture for providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data, in accordance with one embodiment.

FIG. 2 is a block diagram of a process for providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data, in accordance with one embodiment.

FIG. 3 is a flow diagram of a process for providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data, in accordance with one embodiment.

FIG. 4 is a flow diagram of a process for providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data, in accordance with one embodiment.

Common reference numerals are used throughout the FIG.s and the detailed description to indicate like elements. One skilled in the art will readily recognize that the above FIG.s are examples and that other architectures, modes of operation, orders of operation, and elements/functions can be provided and implemented without departing from the characteristics and features of the invention, as set forth in the claims.

DETAILED DESCRIPTION

Embodiments will now be discussed with reference to the accompanying FIG.s, which depict one or more exemplary embodiments. Embodiments may be implemented in many different forms and should not be construed as limited to the embodiments set forth herein, shown in the FIG.s, and/or described below. Rather, these exemplary embodiments are provided to allow a complete disclosure that conveys the principles of the invention, as set forth in the claims, to those of skill in the art.

Herein, the term "production environment" includes the various components, or assets, used to deploy, implement, access, and use, a given application as that application is intended to be used. In various embodiments, production environments include multiple assets that are combined, communicatively coupled, virtually and/or physically connected, and/or associated with one another, to provide the production environment implementing the application.

As specific illustrative examples, the assets making up a given production environment can include, but are not limited to, one or more computing environments used to implement the application in the production environment such as a data center, a cloud computing environment, a dedicated hosting environment, and/or one or more other computing environments in which one or more assets used by the application in the production environment are implemented; one or more computing systems or computing entities used to implement the application in the production environment; one or more virtual assets used to implement the application in the production environment; one or more supervisory or control systems, such as hypervisors, or other monitoring and management systems, used to monitor and control assets and/or components of the production environment; one or more communications channels for sending

and receiving data used to implement the application in the production environment; one or more access control systems for limiting access to various components of the production environment, such as firewalls and gateways; one or more traffic and/or routing systems used to direct, control, and/or buffer, data traffic to components of the production environment, such as routers and switches; one or more communications endpoint proxy systems used to buffer, process, and/or direct data traffic, such as load balancers or buffers; one or more secure communication protocols and/or endpoints used to encrypt/decrypt data, such as Secure Sockets Layer (SSL) protocols, used to implement the application in the production environment; one or more databases used to store data in the production environment; one or more internal or external services used to implement the application in the production environment; one or more backend systems, such as backend servers or other hardware used to process data and implement the application in the production environment; one or more software systems used to implement the application in the production environment; and/or any other assets/components making up an actual production environment in which an application is deployed, implemented, accessed, and run, e.g., operated, as discussed herein, and/or as known in the art at the time of filing, and/or as developed after the time of filing.

As used herein, the terms “computing system”, “computing device”, and “computing entity”, include, but are not limited to, a virtual asset; a server computing system; a workstation; a desktop computing system; a mobile computing system, including, but not limited to, smart phones, portable devices, and/or devices worn or carried by a user; a database system or storage cluster; a switching system; a router; any hardware system; any communications system; any form of proxy system; a gateway system; a firewall system; a load balancing system; or any device, subsystem, or mechanism that includes components that can execute all, or part, of any one of the processes and/or operations as described herein.

In addition, as used herein, the terms computing system and computing entity, can denote, but are not limited to, systems made up of multiple: virtual assets; server computing systems; workstations; desktop computing systems; mobile computing systems; database systems or storage clusters; switching systems; routers; hardware systems; communications systems; proxy systems; gateway systems; firewall systems; load balancing systems; or any devices that can be used to perform the processes and/or operations as described herein.

As used herein, the term “computing environment” includes, but is not limited to, a logical or physical grouping of connected or networked computing systems and/or virtual assets using the same infrastructure and systems such as, but not limited to, hardware systems, software systems, and networking/communications systems. Typically, computing environments are either known environments, e.g., “trusted” environments, or unknown, e.g., “untrusted” environments. Typically, trusted computing environments are those where the assets, infrastructure, communication and networking systems, and security systems associated with the computing systems and/or virtual assets making up the trusted computing environment, are either under the control of, or known to, a party.

In various embodiments, each computing environment includes allocated assets and virtual assets associated with, and controlled or used to create, and/or deploy, and/or operate an application.

In various embodiments, one or more cloud computing environments are used to create, and/or deploy, and/or operate an application that can be any form of cloud computing environment, such as, but not limited to, a public cloud; a private cloud; a virtual private network (VPN); a subnet; a Virtual Private Cloud (VPC); a sub-net or any security/communications grouping; or any other cloud-based infrastructure, sub-structure, or architecture, as discussed herein, and/or as known in the art at the time of filing, and/or as developed after the time of filing.

In many cases, a given application or service may utilize, and interface with, multiple cloud computing environments, such as multiple VPCs, in the course of being created, and/or deployed, and/or operated.

As used herein, the term “virtual asset” includes any virtualized entity or resource, and/or virtualized part of an actual, or “bare metal” entity. In various embodiments, the virtual assets can be, but are not limited to, virtual machines, virtual servers, and instances implemented in a cloud computing environment; databases associated with a cloud computing environment, and/or implemented in a cloud computing environment; services associated with, and/or delivered through, a cloud computing environment; communications systems used with, part of, or provided through, a cloud computing environment; and/or any other virtualized assets and/or sub-systems of “bare metal” physical devices such as mobile devices, remote sensors, laptops, desktops, point-of-sale devices, etc., located within a data center, within a cloud computing environment, and/or any other physical or logical location, as discussed herein, and/or as known/available in the art at the time of filing, and/or as developed/made available after the time of filing.

In various embodiments, any, or all, of the assets making up a given production environment discussed herein, and/or as known in the art at the time of filing, and/or as developed after the time of filing, can be implemented as one or more virtual assets.

In one embodiment, two or more assets, such as computing systems and/or virtual assets, and/or two or more computing environments, are connected by one or more communications channels including but not limited to, Secure Sockets Layer communications channels and various other secure communications channels, and/or distributed computing system networks, such as, but not limited to: a public cloud; a private cloud; a virtual private network (VPN); a subnet; any general network, communications network, or general network/communications network system; a combination of different network types; a public network; a private network; a satellite network; a cable network; or any other network capable of allowing communication between two or more assets, computing systems, and/or virtual assets, as discussed herein, and/or available or known at the time of filing, and/or as developed after the time of filing.

As used herein, the term “network” includes, but is not limited to, any network or network system such as, but not limited to, a peer-to-peer network, a hybrid peer-to-peer network, a Local Area Network (LAN), a Wide Area Network (WAN), a public network, such as the Internet, a private network, a cellular network, any general network, communications network, or general network/communications network system; a wireless network; a wired network; a wireless and wired combination network; a satellite network; a cable network; any combination of different network types; or any other system capable of allowing communication between two or more assets, virtual assets, and/or computing systems, whether available or known at the time of filing or as later developed.

As used herein, the term “user” includes, but is not limited to, any party, parties, entity, and/or entities using, or otherwise interacting with any of the methods or systems discussed herein. For instance, in various embodiments, a user can be, but is not limited to, a person, a commercial entity, an application, a service, and/or a computing system.

As used herein, the term “relationship(s)” includes, but is not limited to, a logical, mathematical, statistical, or other association between one set or group of information, data, and/or users and another set or group of information, data, and/or users, according to one embodiment. The logical, mathematical, statistical, or other association (i.e., relationship) between the sets or groups can have various ratios or correlation, such as, but not limited to, one-to-one, multiple-to-one, one-to-multiple, multiple-to-multiple, and the like, according to one embodiment. As a non-limiting example, if the disclosed tax return preparation system determines a relationship between a first group of data and a second group of data, then a characteristic or subset of a first group of data can be related to, associated with, and/or correspond to one or more characteristics or subsets of the second group of data, or vice-versa, according to one embodiment. Therefore, relationships may represent one or more subsets of the second group of data that are associated with one or more subsets of the first group of data, according to one embodiment. In one embodiment, the relationship between two sets or groups of data includes, but is not limited to similarities, differences, and correlations between the sets or groups of data.

As used herein, the terms “interview” and “interview process” include, but are not limited to, an electronic, software-based, and/or automated delivery of multiple questions to a user and an electronic, software-based, and/or automated receipt of responses from the user to the questions, according to various embodiments.

Hardware Architecture

FIG. 1 illustrates a block diagram of a production environment **100** for providing estimated tax refund data to a user of a tax return preparation system, according to one embodiment. Embodiments of the present disclosure provide methods and systems for providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data, according to one embodiment. Embodiments of the present disclosure receive current user tax related data associated with the user in connection with a tax return preparation interview. Embodiments of the present disclosure gather, generate, or retrieve tax rules data related to rules and procedures for providing tax return preparation services to the user. Embodiments of the present disclosure also gather historical tax related data associated with previous users of the tax return preparation system. Embodiments of the present disclosure utilize the current user tax related data and the historical tax related data to generate statistical inferences about data that has not yet been provided by the user during the tax return preparation interview. Embodiments of the present disclosure combine these statistical inferences about the user with the tax rules data to generate estimated tax refund data corresponding to an estimated tax refund of the user. In particular, embodiments of the present disclosure generate the estimated tax refund data by identifying, from the historical tax related data, one or more subsets of historical users that share characteristics with the user based on the current user tax related data. Embodiments of the present disclosure utilize statistical analysis of the tax rules data and the historical tax related data associated with the one or more subsets of historical users in order to generate

probabilistic inference data including inferences related to current user tax related data that the user has not yet provided to the tax return preparation system. Embodiments of the present disclosure use these statistical inferences to generate estimated tax refund that is likely to be relatively accurate even at early stages of the tax return preparation interview when the user has not yet provided much of the expected current user tax related data. Embodiments of the present disclosure can initially provide the estimated tax refund data as a likely range into which the user’s tax refund will fall. As the tax return preparation interview continues and the user provides additional current user tax related data, the tax return preparation system continues to refine the estimated tax refund data by generating statistical inferences that are based on the additional current user tax related data and on a refined subset of historical users that share characteristics with the current user. Eventually, when the user has provided all of the expected current user tax related data, the tax return preparation system can provide a final tax refund estimate.

Embodiments of the present disclosure can also utilize probabilistic inferences to personalize the tax return preparation interview for the user in other ways. In particular, embodiments of the present disclosure can utilize the probabilistic inference data to transform, rearrange, create, or adjust various portions of the tax return preparation interview to be tailored to the likely characteristics of the user. The personalized tax return preparation interview can include a particular arrangement of tax related topics, selected financial questions, preselected answers to tax related questions, and omission of topics that are likely irrelevant. In this way, embodiments of the present disclosure dynamically personalize a tax return preparation interview to the user based on probabilistic inference data.

In addition, the disclosed method and system for providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data provides for significant improvements to the technical fields of electronic financial management, electronic transaction data processing, data processing, data management, and user experience.

In addition, as discussed above, the disclosed method and system for providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data provides for the processing and storing of smaller amounts of data, i.e., more efficiently collect financial data from the user and providing a tax return preparation interview to the user; thereby eliminating unnecessary data analysis and storage. Consequently, using the disclosed method and system for providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data results in more efficient use of human and non-human resources, fewer processor cycles being utilized, reduced memory utilization, and less communications bandwidth being utilized to relay data to, and from, backend systems and client systems, and various investigative systems and parties. As a result, computing systems are transformed into faster, more efficient, and more effective computing systems by implementing the method and system for providing estimated tax refund data generated from a statistical analysis of historical tax related data and current user tax related data.

The production environment **100** includes a service provider computing environment **110**, a user computing environment **130**, a third-party computing environment **140**, and a public information computing environment **150** for providing estimated tax refund data generated from a statistical

11

analysis of historical tax related data and current user tax related data, according to one embodiment. The computing environments **110**, **130**, **140**, and **150** are communicatively coupled to each other with one or more communication channels **101**, according to one embodiment.

The service provider computing environment **110** represents one or more computing systems such as a server or a distribution center that is configured to receive, execute, and host one or more tax return preparation systems (e.g., applications) for access by one or more users, for providing a personalized tax return preparation interview to a user, according to one embodiment. The service provider computing environment **110** represents a traditional data center computing environment, a virtual asset computing environment (e.g., a cloud computing environment), or a hybrid between a traditional data center computing environment and a virtual asset computing environment, according to one embodiment.

The service provider computing environment **110** includes a tax return preparation system **111**, which is configured to provide estimated tax refund data content to a user.

The tax return preparation system **111** receives current user tax related data from a user, retrieves tax rules data, gathers historical tax related data related to previous users of the tax return preparation system **111**, generates probabilistic inference data based on the historical tax related data and the tax rules data, and provides estimated tax refund data to the user based on the probabilistic inference data, according to one embodiment. The tax return preparation system **111** includes various components, databases, engines, modules, and/or data to support providing dynamic estimated tax refund data to a user, according to one embodiment.

The tax return preparation system **111** includes a user interface module **112**, an interview content pool **113**, a data acquisition module **114**, an inference engine **115**, a common store **116**, and a tax calculation engine **117**, according to one embodiment.

According to an embodiment, the user interface module **112** presents a tax return preparation interview to the user by providing interview content data **119** to the user. The interview content data **119** guides a user through a series of tax topics, asks questions, and invites the user to provide data related to tax topics and questions. The user interface module **112** receives current user tax related data **118** in response to providing interview content data **119**, according to one embodiment. The interview content data **119** includes estimated tax refund data **120** based, at least in part, on the current user tax related data **118**.

According to an embodiment, the user interface module **112** is configured to receive the current user tax related data **118** from the user or from other sources. The current user tax related data **118** includes information, such as, but not limited to, a name of the user, a name of the user's employer, an employer identification number (EID), a job title, annual income, salary and wages, bonuses, a Social Security number, a government identification, a driver's license number, a date of birth, an address, a zip code, home ownership status, marital status, W-2 income, an employer's address, spousal information, children's information, asset information, medical history, occupational information, information regarding dependents, salary and wages, interest income, dividend income, business income, farm income, capital gain income, pension income, IRA distributions, education expenses, health savings account deductions, moving expenses, IRA deductions, student loan interest, tuition and fees, medical and dental expenses, state and local taxes, real

12

estate taxes, personal property tax, mortgage interest, charitable contributions, casualty and theft losses, unreimbursed employee expenses, alternative minimum tax, foreign tax credit, education tax credits, retirement savings contribution, child tax credits, residential energy credits, and any other information that is currently used, that can be used, or that may be used in the future, in a tax return preparation system or in the preparation of financial documents such as a user's tax return, according to various embodiments.

According to an embodiment, the user interface module **112** populates interview content **119** from a content pool **113**. The content pool **113** includes topics **121**, questions **122**, and user experience elements **123**. Each topic **121** can be presented to the user with one or more questions **122** and user experience elements **123**, according to one embodiment. The user experience elements include, but are not limited to, buttons, slides, dialog boxes, text boxes, drop-down menus, banners, tabs, directory trees, links, audio content, video content, and/or other multimedia content for presenting topics and questions to the user and for receiving current user tax related data **118** from the user computing environment **130**.

The user computing environment **130** includes input devices **131** and output devices **132** for communicating with the user, according to one embodiment. The input devices **131** include, but are not limited to, keyboards, mice, microphones, touchpads, touchscreens, digital pens, and the like. The output devices **132** include, but are not limited to, speakers, monitors, touchscreens, and the like.

Returning to the tax return preparation system **111**, the data acquisition module **114** is configured to acquire additional information from various sources to merge with or supplement the current user tax related data **118**, according to one embodiment. For example, while the user interface module **112** may receive current user tax related data **118** from the user in response to questions or prompts, the data acquisition module **114** is configured to gather additional current user tax related data **118** from sources other than the user. For example, the data acquisition module **114** can retrieve previously collected current user tax related data **118** from one or more databases of the tax return preparation system **111**, such as the common store **116**. The data acquisition module **114** can also gather current user tax related data **118** from third-party computing environment **140** or from the public information computing environment **150**. The data acquisition module **114** can also gather current user tax related data **118** from additional service provider systems **127** associated with the tax return preparation system **111**.

In one embodiment, the data acquisition module **114** is configured to gather historical tax related data **124** related to historical users of the tax return preparation system **111**. The historical tax related data **124** can include the same types of data as the current user tax related data **118**, except that the historical tax related data **124** is associated with historical users of the tax return preparation system **111**. According to an embodiment, the historical tax related data **124** can include, for each of a plurality of historical users of the tax return preparation system **111**, some or all of the types of data that might typically be collected from the user as part of a tax return preparation interview. The historical tax related data **124** can include additional types of data that would not normally be collected from the user in a tax return preparation interview.

In one embodiment, the data acquisition module **114** is configured to communicate with additional service provider systems **127** to access financial data **128**. The data acquisi-

tion module **114** imports relevant portions of the financial data **128** into the tax return preparation system **111** and, for example, saves local copies into one or more databases, according to one embodiment.

In one embodiment, the additional service provider systems **127** include a payroll system that manages the payroll of a large number of employers. The data acquisition module **114** is configured to acquire information from the financial data **128**, for use by the tax return preparation system **111** in providing estimated tax refund data to the user, according to one embodiment. Since the financial services provider provides both the tax return preparation system **111** and the payroll system, the service provider computing environment **110** can be configured to share financial data **128** between the various systems. By interfacing with the additional service provider systems **127**, the data acquisition module **114** acquires historical tax related data **124**. The information can include income data, salary data, geographic location data, numbers of exemptions claimed, length of tenure with the employer, banking data, withholding data, investment data, and other types of data that indicate financial and personal characteristics of the employees of the employer.

The additional service provider systems **127** can include financial services other than payroll and tax return preparation systems. For example, the additional service provider systems can include personal tax return preparation systems that manage one or more of banking, investments, credit cards, loans, retirement accounts, budgeting, or financial interests. The data acquisition module **114** can gather financial data from databases associated with the additional service provider systems **127**.

The data acquisition module **114** is configured to acquire data from third parties, according to one embodiment. For example, the data acquisition module **114** requests and receives data from the third-party computing environment **140** to supply or supplement the historical tax related data **124**, according to one embodiment. In one embodiment, the third-party computing environment **140** is configured to automatically transmit financial data to the tax return preparation system **111** (e.g., to the data acquisition module **114**), to be merged into historical tax related data **124**. The third-party computing environment **140** can include, but is not limited to, financial service providers, state institutions, federal institutions, private employers, financial institutions, and any other business, organization, or association that has maintained financial data, that currently maintains financial data, or which may in the future maintain financial data, according to one embodiment. The data acquisition module **114** can also acquire data from sources such as social media sources, such as Twitter, Facebook, LinkedIn, and the like.

In one embodiment, the data acquisition module **114** is configured to acquire additional financial data from the public information computing environment **150**, according to one embodiment. The historical tax related data **124** can be gathered from public record searches of tax records, public information databases, property ownership records, and other public sources of information.

In one embodiment, the tax calculation engine **117** calculates or otherwise generates data values for the various data fields of the user's tax return based on the current user tax related data **118** and tax rules data **129**. As the user provides current user tax related data **118**, the tax calculation engine calculates data values for the tax return of the user based on the user tax related data **118** and the tax rules data **129**. Some data values for the various data fields of the tax returns, or the various data fields of the other tax documents and worksheets associated with the tax return, are numerical

values calculated by the tax calculation engine **117**. Other data values for the various data fields include text strings or numerical values provided directly by the user. The tax calculation engine **117** populates the data fields of the tax return, or other forms or worksheets associated with the tax return, based on the current user tax related data **118** and the tax rules data **129**.

In one embodiment, the tax rules data **129** includes externally generated tax rules data related to tax laws, tax regulations, electronic versions of tax forms, electronic versions of financial worksheets, etc. The tax return preparation system **111** can gather or receive the tax rules data **129** from sources external to the tax return preparation system **111**. The externally generated tax rules data can be received from government sources, from third party sources, or from other sources.

In one embodiment, the tax rules data **129** also includes internal tax rules data. The internal tax rules data includes internally generated data used by the tax return preparation system **111** in order to fill out the various tax forms and worksheets associated with preparation of a tax return and to otherwise comply with tax regulations and rules. The internal tax rules data can include procedures for generating data values for the various lines of financial forms based on current user tax related data **118**. For example, the internal tax rules data can include data that indicates, for each line of the various financial forms and worksheets, what data points or dependencies go into calculating a data value for the line. These data points or dependencies can include lines from the same tax form or worksheet, lines from other tax forms or worksheets, constants, or other data points that may be utilized in generating or calculating a data value for a given line of the tax form or worksheet. The internal tax rules data can include specific mathematical operations, calculations, or relations for generating correct data values for various lines of the financial form or worksheet.

Traditional tax return preparation systems typically generate data values for the tax return based purely on the data that has been provided so far by the user in accordance with the tax rules data utilized by the traditional tax return preparation system. In one example, a traditional tax return preparation system may utilize a particular function in order to calculate the data value for a particular data field of a tax related form. The function may require three input values in order to generate the proper data value. If the user has only supplied data sufficient to provide two of the three input values, then the traditional tax return preparation will simply provide no data value, or worse, an incomplete data value. In the case of a tax refund value, the tax refund value may be based on hundreds of data values provided by the user. During the tax return preparation process, the traditional tax return preparation system may provide an estimated tax refund that is based only on the incomplete data provided by the user up to that point. As the user provides additional data, the estimated tax refund provided by the traditional tax return preparation system can undergo wild swings. For example, after the user of a traditional tax return preparation system enters a gross income, and before the user has entered any data related to taxes withheld or deductions, the traditional tax return preparation system may display an estimated large tax liability to the user because mitigating data has not yet been entered. This can dismay the user and can cause him to abandon the traditional tax return preparation system, even though if the user had continued to input data to the traditional tax return preparation system, the traditional tax return preparation system may have eventually indicated that the user is due a large tax refund.

In one embodiment, the tax return preparation system **111**, in accordance with principles of the present disclosure, utilizes the inference engine **115** to supplement the calculations made by the tax calculation engine **117** at stages of the tax return preparation process in which the user has not yet provided all of the current user tax related data **118** that will be required for a complete tax return. In particular, the tax return preparation system **111** uses the inference engine **115** to analyze the current user tax related data **118**, the tax rules data **129**, and the historical tax related data **124** in order to generate probabilistic inference data **125** that includes probabilistic inferences related to data values not yet provided by the user, but that would be necessary for the tax calculation engine **117** to calculate final data values for the tax return. In particular, the inference engine **115** can compare the current user tax related data **118** to the historical tax related data **124** in order to identify one or more subsets of historical users of the tax return preparation system **111** that have characteristics similar to those included in the current user tax related data **118**. The inference engine **115** analyzes the historical tax related data **124** related to the one or more subsets of historical users that share similarities with the user. The inference engine **115** generates probabilistic inference data **125** based on the current user tax related data **118**, the historical tax related data **124**, and the tax rules data **129**. The inference engine **115** can determine what data types or data values from the historical tax related data **124** should be analyzed based at least in part on the tax rules data **129**. The probabilistic inference data **125** includes inferences related to current user tax related data related to the user that has not yet been obtained by the tax return preparation system **111**. The inference engine **115** uses statistical analysis for each of a selected number of data types or values that have not yet been collected from the user in order to infer what the data is likely to be, based on the one or more subsets of historical users. The inference engine **115** can generate the estimated tax refund data **120** based on the probabilistic inference data **125**.

In one embodiment, the inference engine **115** can generate the estimated tax refund data **120** even early stages of a tax return preparation interview in which the user has only provided a little of the current user tax related data **118** that will be necessary to fully complete the tax return preparation process. The inference engine **115** generates estimated tax refund data **120** based on the limited current user tax related data **118**, the tax rules data **129**, and the historical tax related data **124**. Because the estimated tax refund data **120** is generated based on probabilistic inferences, the estimated tax refund data **120** is likely to be relatively accurate even at the early stages of the tax return preparation interview.

In one embodiment, the inference engine **115** generates estimated tax refund data **120** in the form of a probable tax refund range or distribution. For example, the inference engine **115** can provide an estimated tax refund range that includes the range of tax refunds that fall within a standard deviation of the median tax refund of historical users that share characteristics with the current user based on the current user tax related data **118** supplied by the current user so far. The inference engine **115** can provide an estimated tax refund range based on other statistical or probabilistic considerations.

In one embodiment, the tax return preparation system **111** provides the estimated tax refund data **120** via the user interface module **112** at an early stage of the tax return preparation interview. As the tax return preparation interview continues, the user continues to provide additional current user tax related data **118**. As the user continues to

provide current user tax related data **118**, the inference engine **115** continues to refine the estimated tax refund data **120** based on the additional current user tax related data **118** and on a refined subset of the historical tax related data **124**, as well as in conjunction with the tax rules data **129**. The user interface module **112** provides the refined estimated tax refund data **120** throughout the interview process. Though the estimated tax refund data **120** gradually becomes more accurate throughout the tax return preparation process, the estimated tax refund data **120** does not undergo wild swings or changes that can surprise, confuse, and discourage the user. Instead, the user is encouraged by the stability and accuracy of the estimated tax refund data **120**.

According to one embodiment, as an illustrative example, during the early stages of the tax return preparation interview the user provides current user tax related data **118** indicating that the user has a gross income of \$100,000, is 35 years old, lives in a particular area of Phoenix Ariz., and is employed as a software engineer by a particular employer. The inference engine **115** analyzes the historical tax related data **124** and identifies a subset of historical users that share similar characteristics as those provided by the user. A statistical analysis of the historical tax related data **124** associated with the subset of historical users indicates that 98% of historical users in the subset received tax refunds between \$2500 and \$3500. The inference engine **115** generates estimated tax refund data **120** including the display of an estimated refund of between \$2500 and \$3500. The tax return preparation system presents this estimated refund range to the user even though the user has not yet entered tax withholding data or deduction data. Because the estimated tax refund is generated from the probabilistic inference data **125** that includes an analysis of a large number of historical tax returns, as the user continues to provide current user tax related data **118** throughout the tax return preparation interview, the estimated tax refund is unlikely to vary from the estimated range. As the user continues to enter current user tax related data **118** throughout the tax return preparation process, the inference engine **115** can update the estimated tax refund. At the end of the tax return preparation process the user is pleased to see that the final tax refund value is \$3300, within the estimated range displayed near the beginning of the tax return preparation interview.

In one embodiment, the tax return preparation system **111** can utilize the probabilistic inference data **125** to personalize and enhance the tax return preparation interview in ways other than in providing an estimated tax refund. If the inference engine **115** finds that some inferences can be made with a high probability of being correct, for example beyond a threshold probability, then the inference engine **115** generates probabilistic inference data **125** that includes these inferences that have a high probability of being correct. The inference engine **115** can then generate personalized tax return preparation data based on the probabilistic inference data **125**. The personalized tax return preparation data can include topics that are very likely to be relevant to the user. The personalized tax return preparation data can omit topics that are very likely to be irrelevant to the user. The personalized tax return preparation data can include questions with preselected answers. The estimated tax refund data **120** can include prompts for the user to review or confirm the preselected answers. The personalized tax return preparation data can include estimations of amounts of money owed to or owed by user. All these items can serve to speed up the tax return preparation interview and to improve the user's experience.

In one embodiment, at the beginning of the tax return preparation interview, or even before the tax return preparation interview begins, the user provides current user tax related data. For example, at the beginning of the tax return preparation interview, the user may be prompted to provide basic tax related data such as the age of the user, the address of the user, the gender of the user, a marital status of the user, information relating to children or other dependents of the user, or many other kinds of basic information. Additionally, the user may be prompted to provide data related to a W-2 form such as gross income, tax withholdings, an employer identification number, etc. At this early stage of the tax return preparation interview, the user has only entered a fraction of the total data that may typically be required to complete the full tax return preparation process. Advantageously, the tax return preparation system in accordance with embodiments of the present disclosure, can already begin to personalize the tax return preparation process in a way that enhances and speeds up the tax return preparation interview process for the user. In particular, the inference engine **115** analyzes the current user tax related data **118** and the historical tax related data **124** in order to identify from the historical tax related data one or more subsets of historical users that share characteristics of the user. For example, the inference engine **115** may identify users that reside in a same area as the user, that are a similar age as the user, that share the same employer or a similar employer as the user, that have the same job title as the user, that have a similar income as the user, that have similar tax withholding as the user, that had a similar family situation, etc. The inference engine **115** can then analyze the historical tax related data related to these subsets of users in order to make inferences about the user with regards to data that has not yet been collected from the user. The inference engine **115** can identify data points for which a statistical analysis indicates that there is a high probability of the user having a particular data value. The inference engine **115** can then generate estimated tax refund data **120** or personalized tax return preparation data that takes into account the probabilistic inference data **125**.

In one example, a user is preparing a tax return. In beginning of the tax return preparation interview, the user provides data indicating the user's age, the user's address, the user's occupation, and the user's income. The inference engine **115** analyzes the historical tax related data **124** and finds one or more subsets of historical users that share one or more of these characteristics of the user. The inference engine **115** further analyzes the historical tax related data related to those subsets of historical users in order to make inferences about the user. A statistical analysis of the historical tax related data **124** related to those subsets of historical users indicates that historical users that live in the same or similar areas as the user, that have an income in a similar range as the user, and that have a same marital status as the user are highly likely to be homeowners. The inference engine **115** generates probabilistic inference data **125** indicating that the user is highly likely to be a homeowner. The inference engine **115** generates personalized tax return preparation data based on the probabilistic inference that the user is a homeowner. The personalized tax return preparation data includes providing a question to the user as to whether or not the user is a homeowner and pre-filling an option for "yes". Additionally, the personalized tax return preparation data can include presenting to the user a topic related to mortgage interest deductions based on the inference that the user is a homeowner. The personalized tax return preparation data can also omit topics related to

deductions for those that rented a home. In this way, the tax return preparation system **111** streamlines a tax return preparation interview for the user by inferring answers to some questions on behalf of the user and by presenting some topics and omitting other topics based on this inference. This speeds up the tax return preparation interview process and delivers a more pleasing experience to the user. The tax return preparation system can utilize the tax rules data in order to determine what types of data from the historical tax related data **124** should be analyzed in order to generate probabilistic inference data **125**.

In one embodiment, the tax return preparation system uses the tax rules data, the current user tax related data that has been provided by or obtained from the user, and the historical tax related data related to previous users of the tax return preparation system in order to make probabilistic inferences regarding data that has not yet been provided by the user. For example, a government tax form may include text related to line **5** that says "This value is the lesser of \$6000 and the sum of line **3** and line **4**." The tax rules data includes a specific function for generating the correct value for line **5**. However, during a tax return preparation interview, the user may not yet have provided the data related to line **4**. The tax return preparation system can make a probabilistic inference in order to generate a likely value for line **5** for the user even though the user has not yet provided the value for line **4**. In particular, the tax return preparation system analyzes the tax rules data and identifies the various dependencies for generating the correct value for line **5** and identifies that the value for line **4** is needed. The tax return preparation system accesses historical user related data, identifies historical users that are similar to the current user, retrieves the values for line **4** related to the historical users, and makes a probabilistic inference as to the likely value of line **5** for the user based on the values for line **4** related to the historical users. In this way, the tax return preparation system can utilize tax rules data, historical tax related data, and current user tax related data in order to make probabilistic inferences about the user.

According to an embodiment, the probabilistic inference data **125** can include an inference that the user has made an error in providing the current user tax related data **118**. For example, as the user begins to provide user related financial data at the beginning of the tax return preparation interview, the inference engine **115** can analyze the historical tax related data **124** in order to identify one or more subsets of historical users with similar characteristics as those provided by the user. As the user continues to enter current user tax related data **118**, the inference engine **115** can continue to analyze the additional data entries and can compare them to the statistical distribution of corresponding data entries in the historical tax related data **124** associated with the one or more subsets of the historical users. The inference engine **115** may determine that a data entry made by the user is highly improbable based on the statistical distribution associated with the one or more subsets of historical users. The inference engine **115** may then generate probabilistic inference data **125** that includes an inference that the user has made an error in a particular data entry. The inference engine **115** also generates personalized tax return preparation data that can be provided to the user indicating to the user that the user has possibly made an error. The personalized tax return preparation data provided to the user can highlight the possible error and can prompt the user to review the possibly erroneous data input and make a correction if an error has indeed been made.

As a specific illustrative example in which the tax return preparation system **111** is a tax return preparation system, a user begins a tax return preparation interview and enters data indicating that the user is 25 years old, lives in Denver Colo., has no dependents, and is a high school teacher. The inference engine **115** analyzes the historical tax related data **124** to identify one or more subsets of historical users with characteristics similar to those of the user. As the user continues to enter data, the user makes a data entry indicating that the user has a gross income of \$510,000. The inference engine **115** analyzes the historical tax related data **124** related to the subset of historical users similar to the user. The inference engine **115** performs a statistical analysis of the income reported by the subset of historical users and determines that 99% of them had an income between \$40,000 and \$60,000. The inference engine **115** generates probabilistic inference data **125** including an inference that the user has made an error in entering his gross income because it is highly improbable that the user has an income of \$510,000 when there are no historical users in the subset that have an income in a similar range. The probabilistic inference data **125** infers that the user has made an error, possibly by typing an extra zero. The inference engine **115** generates personalized tax return preparation data that includes a personalized prompt to the user to review the gross income number as entered by the user. The user reviews the gross income amount as prompted by the personalized tax return preparation data and sees that he has indeed entered an extra zero by mistake. The user corrects this error and enters a gross income of \$51,000. The inference engine **115** compares this new income value to the subset of similar users and determines that the new income value is not likely to be an error. The user is grateful that the tax return preparation system found this error in real time so that the error could be corrected with little inconvenience to the user.

In one embodiment, the inference engine **115** can identify the one or more subsets of similar historical users by matching the user to one or more profiles, according to one embodiment. The inference engine **115** identifies one or more profiles with which the user shares financial or personal characteristics and can match the user to one or more of the profiles that share a comparatively large number of characteristics or certain heavily weighted characteristics.

Process

FIG. 2 illustrates a functional flow diagram of a process **200** for providing estimated tax refund data to a user of a tax return preparation system, in accordance with one embodiment.

Referring to FIGS. 1 and 2 together, at block **202**, the user interface module **112** receives current user tax related data associated with a user of a tax return preparation system, according to one embodiment.

At block **204**, the data acquisition module **114** gathers historical tax related data associated with historical users of the tax return preparation system. From block **204**, the process proceeds to block **206**.

At block **206**, the inference engine **115** identifies a subset of the historical users that are similar to the user, according to one embodiment. From block **206**, the process proceeds to block **208**.

At block **208**, the inference engine **115** generates probabilistic inference data by analyzing the historical tax related data and tax rules data, according to one embodiment. From block **208**, the process proceeds to block **210**.

At block **210**, the inference engine **115** generates estimated tax refund data based on the probabilistic inference

data, according to one embodiment. From block **210**, the process proceeds to block **212**.

At block **212**, the user interface module **112** outputs the estimated tax refund data to the user in a tax return preparation interview, according to one embodiment.

Although a particular sequence is described herein for the execution of the process **200**, other sequences can also be implemented.

FIG. 3 illustrates a flow diagram of a process **300** for providing estimated tax refund data to a user of a tax return preparation system, according to various embodiments.

In one embodiment, process **300** for providing estimated tax refund data to a user of a tax return preparation system begins at BEGIN **302** and process flow proceeds to RECEIVE CURRENT USER TAX RELATED DATA ASSOCIATED WITH A USER OF A TAX RETURN PREPARATION SYSTEM **304**.

In one embodiment, at RECEIVE CURRENT USER TAX RELATED DATA ASSOCIATED WITH A USER OF A TAX RETURN PREPARATION SYSTEM **304** process **300** for providing estimated tax refund data to a user of a tax return preparation system receives current user tax related data associated with a user of a tax return preparation system.

In one embodiment, once process **300** for providing estimated tax refund data to a user of a tax return preparation system receives current user tax related data associated with a user of a tax return preparation system at RECEIVE CURRENT USER TAX RELATED DATA ASSOCIATED WITH A USER OF A TAX RETURN PREPARATION SYSTEM **304** process flow proceeds to GENERATE DATA VALUES RELATED TO A TAX RETURN OF THE USER BASED ON THE CURRENT USER TAX RELATED DATA AND TAX RULES DATA RELATED TO PROCEDURES FOR PREPARING TAX RETURNS **306**.

In one embodiment, at GENERATE DATA VALUES RELATED TO A TAX RETURN OF THE USER BASED ON THE CURRENT USER TAX RELATED DATA AND TAX RULES DATA RELATED TO PROCEDURES FOR PREPARING TAX RETURNS **306**, process **300** for providing estimated tax refund data to a user of a tax return preparation system generates data values related to a tax return of the user based on the current user tax related data and tax rules data related to procedures for preparing tax returns.

In one embodiment, once process **300** for providing estimated tax refund data to a user of a tax return preparation system generates data values related to a tax return of the user based on the current user tax related data and tax rules data related to procedures for preparing tax returns at GENERATE DATA VALUES RELATED TO A TAX RETURN OF THE USER BASED ON THE CURRENT USER TAX RELATED DATA AND TAX RULES DATA RELATED TO PROCEDURES FOR PREPARING TAX RETURNS **306**, process flow proceeds to RECEIVE HISTORICAL TAX RELATED DATA RELATED TO PREVIOUSLY PREPARED TAX RETURNS OF HISTORICAL USERS OF THE TAX RETURN PREPARATION SYSTEM **308**.

In one embodiment, at RECEIVE HISTORICAL TAX RELATED DATA RELATED TO PREVIOUSLY PREPARED TAX RETURNS OF HISTORICAL USERS OF THE TAX RETURN PREPARATION SYSTEM **308**, process **300** for providing estimated tax refund data to a user of a tax return preparation system receives historical tax related data related to previously prepared tax returns of historical users of the tax return preparation system.

In one embodiment, once process **300** for providing estimated tax refund data to a user of a tax return preparation system receives historical tax related data related to previously prepared tax returns of historical users of the tax return preparation system at RECEIVE HISTORICAL TAX RELATED DATA RELATED TO PREVIOUSLY PREPARED TAX RETURNS OF HISTORICAL USERS OF THE TAX RETURN PREPARATION SYSTEM **308**, process flow proceeds to IDENTIFY A SUBSET OF THE PREVIOUSLY PREPARED TAX RETURNS THAT INCLUDE SIMILARITIES WITH THE CURRENT USER TAX RELATED DATA **310**.

In one embodiment, at IDENTIFY A SUBSET OF THE PREVIOUSLY PREPARED TAX RETURNS THAT INCLUDE SIMILARITIES WITH THE CURRENT USER TAX RELATED DATA **310** the process **300** for providing estimated tax refund data to a user of a tax return preparation system identifies a subset of the previously prepared tax returns that include similarities with the current user tax related data.

In one embodiment, once process **300** for providing estimated tax refund data to a user of a tax return preparation system identifies a subset of the previously prepared tax returns that include similarities with the current user tax related data at IDENTIFY A SUBSET OF THE PREVIOUSLY PREPARED TAX RETURNS THAT INCLUDE SIMILARITIES WITH THE CURRENT USER TAX RELATED DATA **310** process flow proceeds to GENERATE PROBABILISTIC INFERENCE DATA BY ANALYZING THE TAX RULES DATA AND THE HISTORICAL TAX RELATED DATA ASSOCIATED WITH THE SUBSET OF PREVIOUSLY PREPARED TAX RETURNS **312**.

In one embodiment, at GENERATE PROBABILISTIC INFERENCE DATA BY ANALYZING THE TAX RULES DATA AND THE HISTORICAL TAX RELATED DATA ASSOCIATED WITH THE SUBSET OF PREVIOUSLY PREPARED TAX RETURNS **312** the process **300** for providing estimated tax refund data to a user of a tax return preparation system generates probabilistic inference data by analyzing the tax rules data and the historical tax related data associated with the subset of previously prepared tax returns.

In one embodiment, once process **300** for providing estimated tax refund data to a user of a tax return preparation system generates probabilistic inference data by analyzing the tax rules data and the historical tax related data associated with the subset of previously prepared tax returns at GENERATE PROBABILISTIC INFERENCE DATA BY ANALYZING THE TAX RULES DATA AND THE HISTORICAL TAX RELATED DATA ASSOCIATED WITH THE SUBSET OF PREVIOUSLY PREPARED TAX RETURNS **312**, process flow proceeds to GENERATE ESTIMATED TAX REFUND DATA BASED ON THE PROBABILISTIC INFERENCE DATA AND INCLUDING AN ESTIMATED TAX REFUND **314**.

In one embodiment, at GENERATE ESTIMATED TAX REFUND DATA BASED ON THE PROBABILISTIC INFERENCE DATA AND INCLUDING AN ESTIMATED TAX REFUND **314** the process **300** for providing estimated tax refund data to a user of a tax return preparation system generates estimated tax refund data based on the probabilistic inference data and including an estimated tax refund.

In one embodiment, once the process **300** for providing estimated tax refund data to a user of a tax return preparation system generates estimated tax refund data based on the probabilistic inference data and including an estimated tax refund at GENERATE ESTIMATED TAX REFUND DATA

BASED ON THE PROBABILISTIC INFERENCE DATA AND INCLUDING AN ESTIMATED TAX REFUND **314**, process flow proceeds to PROVIDE THE ESTIMATED TAX REFUND DATA TO THE USER IN A TAX RETURN PREPARATION INTERVIEW **316**.

In one embodiment, at PROVIDE THE ESTIMATED TAX REFUND DATA TO THE USER IN A TAX RETURN PREPARATION INTERVIEW **316** the process **300** for providing estimated tax refund data to a user of a tax return preparation system provides the estimated tax refund data to the user in a tax return preparation interview.

In one embodiment, once the process **300** for providing estimated tax refund data to a user of a tax return preparation system provides the estimated tax refund data to the user in a tax return preparation interview at PROVIDE THE ESTIMATED TAX REFUND DATA TO THE USER IN A TAX RETURN PREPARATION INTERVIEW **316**, process flow proceeds to END **318**.

In one embodiment, at END **318** the process for providing estimated tax refund data to a user of a tax return preparation system is exited to await new data and/or instructions.

FIG. 4 illustrates a flow diagram of a process **400** for providing estimated tax refund data to a user of a tax return preparation system, according to various embodiments.

In one embodiment, process **400** for providing estimated tax refund data to a user of a tax return preparation system begins at BEGIN **402** and process flow proceeds to RECEIVE CURRENT USER TAX RELATED DATA ASSOCIATED WITH A USER OF A TAX RETURN PREPARATION SYSTEM **404**.

In one embodiment, at RECEIVE CURRENT USER TAX RELATED DATA ASSOCIATED WITH A USER OF A TAX RETURN PREPARATION SYSTEM **404** process **400** for providing estimated tax refund data to a user of a tax return preparation system receives current user tax related data associated with a user of a tax return preparation system.

In one embodiment, once process **400** for providing estimated tax refund data to a user of a tax return preparation system receives current user tax related data associated with a user of a tax return preparation system at RECEIVE CURRENT USER TAX RELATED DATA ASSOCIATED WITH A USER OF A TAX RETURN PREPARATION SYSTEM **404** process flow proceeds to RECEIVE HISTORICAL TAX RELATED DATA RELATED TO HISTORICAL USERS OF THE TAX RETURN PREPARATION SYSTEM **406**.

In one embodiment, at RECEIVE HISTORICAL TAX RELATED DATA RELATED TO HISTORICAL USERS OF THE TAX RETURN PREPARATION SYSTEM **406**, process **400** for providing estimated tax refund data to a user of a tax return preparation system receives historical tax related data related to historical users of the tax return preparation system.

In one embodiment, once process **400** for providing estimated tax refund data to a user of a tax return preparation system receives historical tax related data related to historical users of the tax return preparation system at RECEIVE HISTORICAL TAX RELATED DATA RELATED TO HISTORICAL USERS OF THE TAX RETURN PREPARATION SYSTEM **406**, process flow proceeds to GENERATE ESTIMATED TAX REFUND DATA INCLUDING AN ESTIMATED TAX REFUND FOR THE USER BY MAKING PROBABILISTIC INFERENCES ABOUT A TAX SITUATION OF THE USER BASED ON THE HISTORI-

CAL TAX RELATED DATA AND THE TAX RULES DATA RELATED TO RULES FOR PREPARING TAX RETURNS **408**.

In one embodiment, at GENERATE ESTIMATED TAX REFUND DATA INCLUDING AN ESTIMATED TAX REFUND FOR THE USER BY MAKING PROBABILISTIC INFERENCES ABOUT A TAX SITUATION OF THE USER BASED ON THE HISTORICAL TAX RELATED DATA AND THE TAX RULES DATA RELATED TO RULES FOR PREPARING TAX RETURNS **408**, process **400** for providing estimated tax refund data to a user of a tax return preparation system generates estimated tax refund data including an estimated tax refund for the user by making probabilistic inferences about a tax situation of the user based on the historical tax related data and the tax rules data related to rules for preparing tax returns.

In one embodiment, once process **400** for providing estimated tax refund data to a user of a tax return preparation system generates estimated tax refund data including an estimated tax refund for the user by making probabilistic inferences about a tax situation of the user based on the historical tax related data and the tax rules data related to rules for preparing tax returns at GENERATE ESTIMATED TAX REFUND DATA INCLUDING AN ESTIMATED TAX REFUND FOR THE USER BY MAKING PROBABILISTIC INFERENCES ABOUT A TAX SITUATION OF THE USER BASED ON THE HISTORICAL TAX RELATED DATA AND THE TAX RULES DATA RELATED TO RULES FOR PREPARING TAX RETURNS **408**, process flow proceeds to PROVIDE THE ESTIMATED TAX REFUND DATA TO THE USER IN A TAX RETURN PREPARATION INTERVIEW **410**.

In one embodiment, at PROVIDE THE ESTIMATED TAX REFUND DATA TO THE USER IN A TAX RETURN PREPARATION INTERVIEW **410** the process **400** for providing estimated tax refund data to a user of a tax return preparation system provides the estimated tax refund data to the user in a tax return preparation interview.

In one embodiment, once process **400** for providing estimated tax refund data to a user of a tax return preparation system provides the estimated tax refund data to the user in a tax return preparation interview at PROVIDE THE ESTIMATED TAX REFUND DATA TO THE USER IN A TAX RETURN PREPARATION INTERVIEW **410** process flow proceeds to END **412**.

As noted above, the specific illustrative examples discussed above are but illustrative examples of implementations of embodiments of the method or process for providing a tax refund confidence indicator to a user. Those of skill in the art will readily recognize that other implementations and embodiments are possible. Therefore, the discussion above should not be construed as a limitation on the claims provided below.

In one embodiment, a computing system implemented method provides estimated tax refund data to a user of a tax return preparation system. The method includes receiving current user tax related data associated with a user of a tax return preparation system, receiving historical tax related data related to historical users of the tax return preparation system, and generating estimated tax refund data including an estimated tax refund for the user by making probabilistic inferences about a tax situation of the user based on the historical tax related data and the tax rules data related to rules for preparing tax returns. The method also includes providing the estimated tax refund data to the user in a tax return preparation interview.

In one embodiment, a system provides estimated tax refund data to a user of a tax return preparation system. The system includes at least one processor and at least one memory coupled to the at least one processor, the at least one memory having stored therein instructions which, when executed by any set of the one or more processors, perform a process. The process includes receiving current user tax related data associated with a user of a tax return preparation system, generating data values related to a tax return of the user based on the current user tax related data and tax rules data related to procedures for preparing tax returns, and receiving historical tax related data related to previously prepared tax returns of historical users of the tax return preparation system. The process includes identifying a subset of the previously prepared tax returns that include similarities with the current user tax related data, generating probabilistic inference data by analyzing the tax rules data and the historical tax related data associated with the subset of previously prepared tax returns, and generating estimated tax refund data based on the probabilistic inference data and including an estimated tax refund. The process also includes providing the estimated tax refund data to the user in a tax return preparation interview.

In one embodiment, a non-transitory computer-readable medium has a plurality of computer-executable instructions which, when executed by a processor, performs a method for providing estimated tax refund data to a user of a tax return preparation system. The instructions include a user interface module configured to receive current user tax related data associated with a user of a tax return preparation system during a tax return preparation interview. The instructions include an information acquisition module configured to gather historical tax related data related to previously prepared tax returns of historical users of the tax return preparation system. The instructions include an inference engine configured to identify a subset of the previously prepared tax returns that include similarities with the current user tax related data and to generate estimated tax refund data including an estimated tax refund of the user by analyzing tax rules data and the historical tax related data associated with the subset of previously prepared tax returns by generating probabilistic inference data related to one or more probabilistic inferences about the user based on the previously prepared tax returns and the tax rules data. The user interface module is configured to output the estimated tax refund data to the user.

In the discussion above, certain aspects of one embodiment include process steps and/or operations and/or instructions described herein for illustrative purposes in a particular order and/or grouping. However, the particular order and/or grouping shown and discussed herein are illustrative only and not limiting. Those of skill in the art will recognize that other orders and/or grouping of the process steps and/or operations and/or instructions are possible and, in some embodiments, one or more of the process steps and/or operations and/or instructions discussed above can be combined and/or deleted. In addition, portions of one or more of the process steps and/or operations and/or instructions can be re-grouped as portions of one or more other of the process steps and/or operations and/or instructions discussed herein. Consequently, the particular order and/or grouping of the process steps and/or operations and/or instructions discussed herein do not limit the scope of the invention as claimed below.

As discussed in more detail above, using the above embodiments, with little or no modification and/or input, there is considerable flexibility, adaptability, and opportu-

nity for customization to meet the specific needs of various parties under numerous circumstances.

In the discussion above, certain aspects of one embodiment include process steps and/or operations and/or instructions described herein for illustrative purposes in a particular order and/or grouping. However, the particular order and/or grouping shown and discussed herein are illustrative only and not limiting. Those of skill in the art will recognize that other orders and/or grouping of the process steps and/or operations and/or instructions are possible and, in some embodiments, one or more of the process steps and/or operations and/or instructions discussed above can be combined and/or deleted. In addition, portions of one or more of the process steps and/or operations and/or instructions can be re-grouped as portions of one or more other of the process steps and/or operations and/or instructions discussed herein. Consequently, the particular order and/or grouping of the process steps and/or operations and/or instructions discussed herein do not limit the scope of the invention as claimed below.

The present invention has been described in particular detail with respect to specific possible embodiments. Those of skill in the art will appreciate that the invention may be practiced in other embodiments. For example, the nomenclature used for components, capitalization of component designations and terms, the attributes, data structures, or any other programming or structural aspect is not significant, mandatory, or limiting, and the mechanisms that implement the invention or its features can have various different names, formats, or protocols. Further, the system or functionality of the invention may be implemented via various combinations of software and hardware, as described, or entirely in hardware elements. Also, particular divisions of functionality between the various components described herein are merely exemplary, and not mandatory or significant. Consequently, functions performed by a single component may, in other embodiments, be performed by multiple components, and functions performed by multiple components may, in other embodiments, be performed by a single component.

Some portions of the above description present the features of the present invention in terms of algorithms and symbolic representations of operations, or algorithm-like representations, of operations on information/data. These algorithmic or algorithm-like descriptions and representations are the means used by those of skill in the art to most effectively and efficiently convey the substance of their work to others of skill in the art. These operations, while described functionally or logically, are understood to be implemented by computer programs or computing systems. Furthermore, it has also proven convenient at times to refer to these arrangements of operations as steps or modules or by functional names, without loss of generality.

Unless specifically stated otherwise, as would be apparent from the above discussion, it is appreciated that throughout the above description, discussions utilizing terms such as, but not limited to, “activating”, “accessing”, “adding”, “aggregating”, “alerting”, “applying”, “analyzing”, “associating”, “calculating”, “capturing”, “categorizing”, “classifying”, “comparing”, “creating”, “defining”, “detecting”, “determining”, “distributing”, “eliminating”, “encrypting”, “extracting”, “filtering”, “forwarding”, “generating”, “identifying”, “implementing”, “informing”, “monitoring”, “obtaining”, “posting”, “processing”, “providing”, “receiving”, “requesting”, “saving”, “sending”, “storing”, “substituting”, “transferring”, “transforming”, “transmitting”, “using”, etc., refer to the action and process of a computing

system or similar electronic device that manipulates and operates on data represented as physical (electronic) quantities within the computing system memories, registers, caches or other information storage, transmission or display devices.

The present invention also relates to an apparatus or system for performing the operations described herein. This apparatus or system may be specifically constructed for the required purposes, or the apparatus or system can comprise a general purpose system selectively activated or configured/reconfigured by a computer program stored on a computer program product as discussed herein that can be accessed by a computing system or other device.

Those of skill in the art will readily recognize that the algorithms and operations presented herein are not inherently related to any particular computing system, computer architecture, computer or industry standard, or any other specific apparatus. Various general purpose systems may also be used with programs in accordance with the teaching herein, or it may prove more convenient/efficient to construct more specialized apparatuses to perform the required operations described herein. The required structure for a variety of these systems will be apparent to those of skill in the art, along with equivalent variations. In addition, the present invention is not described with reference to any particular programming language and it is appreciated that a variety of programming languages may be used to implement the teachings of the present invention as described herein, and any references to a specific language or languages are provided for illustrative purposes only and for enablement of the contemplated best mode of the invention at the time of filing.

The present invention is well suited to a wide variety of computer network systems operating over numerous topologies. Within this field, the configuration and management of large networks comprise storage devices and computers that are communicatively coupled to similar or dissimilar computers and storage devices over a private network, a LAN, a WAN, a private network, or a public network, such as the Internet.

It should also be noted that the language used in the specification has been principally selected for readability, clarity and instructional purposes, and may not have been selected to delineate or circumscribe the inventive subject matter. Accordingly, the disclosure of the present invention is intended to be illustrative, but not limiting, of the scope of the invention, which is set forth in the claims below.

In addition, the operations shown in the FIG.s, or as discussed herein, are identified using a particular nomenclature for ease of description and understanding, but other nomenclature is often used in the art to identify equivalent operations.

Therefore, numerous variations, whether explicitly provided for by the specification or implied by the specification or not, may be implemented by one of skill in the art in view of this disclosure.

What is claimed is:

1. A system for probabilistically predicting a tax refund range for a user, the system located in a service provider computing environment and comprising:
 - one or more processors; and
 - at least one memory coupled to the one or more processors and storing instructions that, when executed by the one or more processors, causes the system to perform operations including:

27

receiving, via a user interface module in connection with a user device located in a user computing environment, user data associated with a system user;

transforming the user data into a prediction of the system user's tax refund range by:

accessing a set of tax rules retrieved from at least one of a public information computing environment or a third party computing environment;

generating, from the user data, tax return data for the system user based on the set of tax rules;

retrieving, from a system database, a set of prior tax returns related to prior users of the system;

identifying a subset of the prior users that share a characteristic with the system user based on the set of prior tax returns and the tax return data;

generating at least one statistical inference about characteristics of the system user that have not yet been collected from the system user based on the prior tax returns related to the subset of prior users;

determining, for each respective inference of the at least one statistical inference, a probability that the respective inference is correct based on a probabilistic analysis of the tax return data; and

in response to at least one of the determined probabilities being greater than a value, generating the prediction of the system user's tax refund range;

providing, via the user interface module, the system user with the generated prediction;

continuously refining the generated prediction by:

receiving, via the user interface module, additional user data associated with the system user;

identifying additional subsets of the prior users that share characteristics with the system user based on the additional user data;

generating additional inferences about characteristics of the system user that have not yet been collected from the system user based on the additional subsets of prior users;

determining additional probabilities that the additional inferences are correct based on additional probabilistic analyses; and

refining the generated prediction based on the additional probabilities; and

providing, via the user interface module, the system user with the refined prediction.

2. The system of claim 1, wherein execution of the instructions causes the system to perform operations further including:

generating an estimated tax liability for the system user.

3. The system of claim 1, wherein execution of the instructions causes the system to perform operations further including:

identifying a data entry made by the system user that is highly improbable to be correct; and

indicating, to the system user, that the system user has possibly made an error related to the data entry.

4. The system of claim 1, wherein the set of tax rules are related to current tax laws.

5. The system of claim 1, wherein generating the statistical inferences is based on at least one of a z-score, a logistic function, or a Monte Carlo integration.

6. The system of claim 1, wherein the set of tax rules relate to at least one of a tax form or a tax worksheet.

7. The system of claim 1, wherein generating the prediction includes:

28

identifying an incomplete field among the system user's tax return;

identifying one or more prior fields among the prior tax returns corresponding to the incomplete field; and

determining a statistical distribution of values for the incomplete field based on the one or more prior fields.

8. The system of claim 7, wherein generating the prediction further includes:

inferring a value for the incomplete field from the statistical distribution of values.

9. The system of claim 8, wherein the inferred value is used to generate the prediction of the system user's tax refund range.

10. The system of claim 9, wherein the generated tax refund range falls within a standard deviation of a median tax refund of the subset of prior users.

11. A non-transitory computer-readable medium storing instructions that, when executed by one or more processors of a system, causes the system to perform operations comprising:

receiving, via a user interface module in connection with a user device located in a user computing environment, user data associated with a system user;

transforming the user data into a prediction of the system user's tax refund range by:

accessing a set of tax rules retrieved from at least one of a public information computing environment or a third party computing environment;

generating, from the user data, tax return data for the system user based on the set of tax rules;

retrieving, from a system database, a set of prior tax returns related to prior users of the system;

identifying a subset of the prior users that share a characteristic with the system user based on the set of prior tax returns and the tax return data;

generating at least one statistical inference about characteristics of the system user that have not yet been collected from the system user based on the prior tax returns related to the subset of prior users;

determining, for each respective inference of the at least one statistical inference, a probability that the respective inference is correct based on a probabilistic analysis of the tax return data; and

in response to at least one of the determined probabilities being greater than a value, generating the prediction of the system user's tax refund range;

providing, via the user interface module, the system user with the generated prediction;

continuously refining the generated prediction by:

receiving, via the user interface module, additional user data associated with the system user;

identifying additional subsets of the prior users that share characteristics with the system user based on the additional user data;

generating additional inferences about characteristics of the system user that have not yet been collected from the system user based on the additional subsets of prior users;

determining additional probabilities that the additional inferences are correct based on additional probabilistic analyses; and

refining the generated prediction based on the additional probabilities; and

providing, via the user interface module, the system user with the refined prediction.

12. The non-transitory computer-readable medium of claim 11, wherein execution of the instructions causes the system to perform operations further including:

identifying an incomplete field among the system user's tax return;

identifying one or more prior fields among the prior tax returns corresponding to the incomplete field; and

determining a statistical distribution of values for the incomplete field based on the one or more prior fields.

13. The non-transitory computer-readable medium of claim 12, wherein generating the prediction further includes: inferring a value for the incomplete field from the statistical distribution of values.

14. The non-transitory computer-readable medium of claim 13, wherein the inferred value is used to generate the prediction of the system user's tax refund range and wherein the generated tax refund range falls within a standard deviation of a median tax refund of the subset of prior users.

15. A method for probabilistically predicting a tax refund range for a user, the method performed by one or more processors of a system and comprising:

receiving, via a user interface module in connection with a user device located in a user computing environment, user data associated with a system user;

transforming the user data into a prediction of the system user's tax refund range by:

accessing a set of tax rules retrieved from at least one of a public information computing environment or a third party computing environment;

generating, from the user data, tax return data for the system user based on the set of tax rules;

retrieving, from a system database, a set of prior tax returns related to prior users of the system;

identifying a subset of the prior users that share a characteristic with the system user based on the set of prior tax returns and the tax return data;

generating at least one statistical inference about characteristics of the system user that have not yet been collected from the system user based on the prior tax returns related to the subset of prior users;

determining, for each respective inference of the at least one statistical inference, a probability that the respective inference is correct based on a probabilistic analysis of the tax return data; and

in response to at least one of the determined probabilities being greater than a value, generating the prediction of the system user's tax refund range;

providing, via the user interface module, the system user with the generated prediction continuously refining the generated prediction by:

receiving, via the user interface module, additional user data associated with the system user;

identifying additional subsets of the prior users that share characteristics with the system user based on the additional user data;

generating additional inferences about characteristics of the system user that have not yet been collected from the system user based on the additional subsets of prior users;

determining additional probabilities that the additional inferences are correct based on additional probabilistic analyses; and

refining the generated prediction based on the additional probabilities; and

providing, via the user interface module, the system user with the refined prediction.

16. The method of claim 15, further comprising:

generating an estimated tax liability for the system user.

17. The method of claim 15, wherein the set of tax rules are related to current tax laws.

18. The method of claim 15, wherein generating the statistical inferences is based on at least one of a z-score, a logistic function, or a Monte Carlo integration.

19. The method of claim 15, wherein the set of tax rules relate to at least one of a tax form or a tax worksheet.

20. The method of claim 15, wherein generating the prediction includes:

identifying an incomplete field among the system user's tax return;

identifying one or more prior fields among the prior tax returns corresponding to the incomplete field; and determining a statistical distribution of values for the incomplete field based on the one or more prior fields.

21. The method of claim 20, wherein generating the prediction further includes:

inferring a value for the incomplete field from the statistical distribution of values.

22. The method of claim 21, wherein the inferred value is used to generate the prediction of the system user's tax refund range.

23. The method of claim 22, wherein the generated tax refund range falls within a standard deviation of a median tax refund of the subset of prior users.

24. The method of claim 15, further comprising:

identifying a data entry made by the system user that is highly improbable to be correct; and

indicating, to the system user, that the system user has possibly made an error related to the data entry.
