(57) **ABSTRACT**

Related U.S. Application Data

(63) Continuation of application No. 16/272,075, filed on Feb. 11, 2019, now Pat. No. 10,720,735, which is a (Continued)

An interconnection system with a compliant shield between a connector and a substrate such as a PCB. The compliant shield may provide current flow paths between shields internal to the connector and ground structures of the PCB. The connector, compliant shield and PCB may be configured to provide current flow in locations relative to signal conductors that provide desirable signal integrity for signals carried by the signal conductors. In some embodiments, the current flow paths may be adjacent the signal conductors, offset in a transverse direction from an axis of a pair of conductors. Such paths may be created by tabs extending from connector shields. A compliant conductive member of the compliant shield may contact the tabs and a conductive pad on a surface of the PCB. Shadow vias, running from the surface pad to internal ground structures may be positioned adjacent the tip of the tabs.

**COMPLIANT SHIELD FOR VERY HIGH
SPEED, HIGH DENSITY ELECTRICAL
INTERCONNECTION**

CROSS REFERENCE TO RELATED
APPLICATIONS

This patent application is a continuation of U.S. patent application Ser. No. 16/272,075, now U.S. Pat. No. 10,720,735, filed on Feb. 11, 2019 and entitled “Compliant Shield for Very High Speed, High Density Electrical Interconnection,” which is hereby incorporated herein by reference in its entirety. U.S. patent application Ser. No. 16/272,075 is a continuation of U.S. patent application Ser. No. 15/788,602, now U.S. Pat. No. 10,205,286, filed on Oct. 19, 2017 and entitled “Compliant Shield for Very High Speed, High Density Electrical Interconnection,” which is hereby incorporated herein by reference in its entirety. U.S. patent application Ser. No. 15/788,602 claims priority to and the benefit of: U.S. Provisional Patent Application Ser. No. 62/410,004, filed on Oct. 19, 2016 and entitled “Compliant Shield for Very High Speed, High Density Electrical Interconnection,” which is hereby incorporated herein by reference in its entirety; U.S. Provisional Patent Application Ser. No. 62/468,251, filed on Mar. 7, 2017 and entitled “Compliant Shield for Very High Speed, High Density Electrical Interconnection,” which is hereby incorporated herein by reference in its entirety; and U.S. Provisional Patent Application Ser. No. 62/525,332, filed on Jun. 27, 2017 and entitled “Compliant Shield for Very High Speed, High Density Electrical Interconnection,” which is hereby incorporated herein by reference in its entirety.

BACKGROUND

This patent application relates generally to interconnection systems, such as those including electrical connectors, used to interconnect electronic assemblies.

Electrical connectors are used in many electronic systems. It is generally easier and more cost effective to manufacture a system as separate electronic assemblies, such as printed circuit boards (“PCBs”), which may be joined together with electrical connectors. A known arrangement for joining several printed circuit boards is to have one printed circuit board serve as a backplane. Other printed circuit boards, called “daughterboards” or “daughtercards,” may be connected through the backplane.

A known backplane is a printed circuit board onto which many connectors may be mounted. Conducting traces in the backplane may be electrically connected to signal conductors in the connectors so that signals may be routed between the connectors. Daughtercards may also have connectors mounted thereon. The connectors mounted on a daughtercard may be plugged into the connectors mounted on the backplane. In this way, signals may be routed among the daughtercards through the backplane. The daughtercards may plug into the backplane at a right angle. The connectors used for these applications may therefore include a right angle bend and are often called “right angle connectors.”

Connectors may also be used in other configurations for interconnecting printed circuit boards and for interconnecting other types of devices, such as cables, to printed circuit boards. Sometimes, one or more smaller printed circuit boards may be connected to another larger printed circuit board. In such a configuration, the larger printed circuit board may be called a “mother board” and the printed circuit boards connected to it may be called daughterboards. Also,

boards of the same size or similar sizes may sometimes be aligned in parallel. Connectors used in these applications are often called “stacking connectors” or “mezzanine connectors.”

Regardless of the exact application, electrical connector designs have been adapted to mirror trends in the electronics industry. Electronic systems generally have gotten smaller, faster, and functionally more complex. Because of these changes, the number of circuits in a given area of an electronic system, along with the frequencies at which the circuits operate, have increased significantly in recent years. Current systems pass more data between printed circuit boards and require electrical connectors that are electrically capable of handling more data at higher speeds than connectors of even a few years ago.

In a high density, high speed connector, electrical conductors may be so close to each other that there may be electrical interference between adjacent signal conductors. To reduce interference, and to otherwise provide desirable electrical properties, shield members are often placed between or around adjacent signal conductors. The shields may prevent signals carried on one conductor from creating “crosstalk” on another conductor. The shield may also impact the impedance of each conductor, which may further contribute to desirable electrical properties.

Examples of shielding can be found in U.S. Pat. Nos. 4,632,476 and 4,806,107, which show connector designs in which shields are used between columns of signal contacts. These patents describe connectors in which the shields run parallel to the signal contacts through both the daughterboard connector and the backplane connector. Cantilevered beams are used to make electrical contact between the shield and the backplane connectors. U.S. Pat. Nos. 5,433,617, 5,429,521, 5,429,520, and 5,433,618 show a similar arrangement, although the electrical connection between the backplane and shield is made with a spring type contact. Shields with torsional beam contacts are used in the connectors described in U.S. Pat. No. 6,299,438. Further shields are shown in U.S. Pre-grant Publication 2013-0109232.

Other connectors have shield plates within only the daughterboard connector. Examples of such connector designs can be found in U.S. Pat. Nos. 4,846,727, 4,975,084, 5,496,183, and 5,066,236. Another connector with shields only within the daughterboard connector is shown in U.S. Pat. No. 5,484,310, U.S. Pat. No. 7,985,097 is a further example of a shielded connector.

Other techniques may be used to control the performance of a connector. For instance, transmitting signals differentially may also reduce crosstalk. Differential signals are carried on a pair of conducting paths, called a “differential pair.” The voltage difference between the conductive paths represents the signal. In general, a differential pair is designed with preferential coupling between the conducting paths of the pair. For example, the two conducting paths of a differential pair may be arranged to run closer to each other than to adjacent signal paths in the connector. No shielding is desired between the conducting paths of the pair, but shielding may be used between differential pairs. Electrical connectors can be designed for differential signals as well as for single-ended signals. Examples of differential electrical connectors are shown in U.S. Pat. Nos. 6,293,827, 6,503,103, 6,776,659, 7,163,421, and 7,794,278.

In an interconnection system, such connectors are attached to printed circuit boards. Typically a printed circuit board is formed as a multi-layer assembly manufactured from stacks of dielectric sheets, sometimes called “prepreg”. Some or all of the dielectric sheets may have a conductive

film on one or both surfaces. Some of the conductive films may be patterned, using lithographic or laser printing techniques, to form conductive traces that are used to make interconnections between circuit boards, circuits and/or circuit elements. Others of the conductive films may be left substantially intact and may act as ground planes or power planes that supply the reference potentials. The dielectric sheets may be formed into an integral board structure such as by pressing the stacked dielectric sheets together under pressure.

To make electrical connections to the conductive traces or ground/power planes, holes may be drilled through the printed circuit board. These holes, or "vias", are filled or plated with metal such that a via is electrically connected to one or more of the conductive traces or planes through which it passes.

To attach connectors to the printed circuit board, contact "tails" from the connectors may be inserted into the vias or attached to conductive pads on a surface of the printed circuit board that are connected to a via.

SUMMARY

Embodiments of a high speed, high density interconnection system are described. Very high speed performance may be achieved in accordance with some embodiments by a compliant shield that provides shielding around contact tails extending from a connector housing. A compliant shield alternatively or additionally may provide current flow in desired locations between shielding members within the connector and ground structures within the printed circuit board.

Accordingly, some embodiments relate to a compliant shield for an electrical connector, the electrical connector comprising a plurality of contact tails for attachment to a printed circuit board. The compliant shield may comprise a conductive body portion comprising a plurality of openings sized and positioned for the contact tails from the electrical connector to pass therethrough. The conductive body provides current flow paths between shields internal to the electrical connector and ground structures of the printed circuit board.

In some embodiments, an electrical connector may have a board mounting face comprising a plurality of contact tails extending therefrom, a plurality of internal shields, and a compliant shield. The compliant shield may comprise a conductive body portion comprising a plurality of openings sized and positioned for the plurality of contact tails to pass therethrough. The conductive body may be in electrical connection with the plurality of internal shields

In some embodiments, an electronic device may be provided. The electronic device may comprise a printed circuit board comprising a surface and a connector mounted to the printed circuit board. The connector may comprise a face parallel with the surface, a plurality of conductive elements extending through the face, a plurality of internal shields, and a compliant shield providing current flow paths between the plurality of internal shields and ground structures of the printed circuit board.

The foregoing is a non-limiting summary of the invention, which is defined by the attached claims.

BRIEF DESCRIPTION OF DRAWINGS

The accompanying drawings are not intended to be drawn to scale. In the drawings, each identical or nearly identical component that is illustrated in various figures is represented

by a like numeral. For purposes of clarity, not every component may be labeled in every drawing. In the drawings:

FIG. 1 is an isometric view of an illustrative electrical interconnection system, in accordance with some embodiments;

FIG. 2 is an isometric view, partially cutaway, of the backplane connector of FIG. 1;

FIG. 3 is an isometric view of a pin assembly of the backplane connector of FIG. 2;

FIG. 4 is an exploded view of the pin assembly of FIG. 3;

FIG. 5 is an isometric view of signal conductors of the pin assembly of FIG. 3;

FIG. 6 is an isometric view, partially exploded, of the daughtercard connector of FIG. 1;

FIG. 7 is an isometric view of a wafer assembly of the daughtercard connector of FIG. 6;

FIG. 8 is an isometric view of wafer modules of the wafer assembly of FIG. 7;

FIG. 9 is an isometric view of a portion of the insulative housing of the wafer assembly of FIG. 7;

FIG. 10 is an isometric view, partially exploded, of a wafer module of the wafer assembly of FIG. 7;

FIG. 11 is an isometric view, partially exploded, of a portion of a wafer module of the wafer assembly of FIG. 7;

FIG. 12 is an isometric view, partially exploded, of a portion of a wafer module of the wafer assembly of FIG. 7;

FIG. 13 is an isometric view of a pair of conducting elements of a wafer module of the wafer assembly of FIG. 7;

FIG. 14A is a side view of the pair of conducting elements of FIG. 13;

DESCRIPTION OF PREFERRED EMBODIMENTS

The inventors have recognized and appreciated that performance of a high density interconnection system may be increased, particularly those that carry very high frequency signals that are necessary to support high data rates, with connector designs that provide for shielding in a region between an electrical connector and a substrate to which the connector is mounted. The shielding may separate contact tails of conductive elements inside the connector. The contact tails may extend from the connector and make electrical connection with a substrate, such as a printed circuit board.

Further, the compliant shield, in conjunction with the connector and printed circuit board to which the connector is mounted, may be configured to provide current paths between the shields within the connector and ground structures in the printed circuit board. These paths may run parallel to current flow paths in signal conductors passing from the connector to the printed circuit board. The inventors have found that such a configuration, though over a small distance, such as 2 mm or less, provides a desirable increase in signal integrity, particularly for high frequency signals.

Such current paths may be provided by conductive elements extending from the connector, which may be tabs. The tabs may be electrically connected to surface pads on the printed circuit board through the compliant shield. The surface pads, in turn, may be connected to inner ground layers of the printed circuit boards through vias receiving contact tails from the connector plus shadow vias. The shadow vias may be positioned adjacent ends of the tabs extending from the connector. Those tabs may be adjacent to contact tails of signal conductors also extending from the connector. Accordingly, a suitably positioned current flow path may exist through shields inside the connector, into the tabs, through the compliant shields, into the pads on the surface of the printed circuit board and to the inner ground layers of the printed circuit board through shadow vias.

Electrical connection through the shield may be facilitated by compliance of the shield such that the shield may be compressed when the connector is mounted to the printed circuit board. Compliance may enable the shield to occupy the space between the connector and the printed circuit board, regardless of variations in separation that may occur as a result of manufacturing tolerances.

Further, the shield may be made of a material that provides force in orthogonal directions when compressed, such as by responding to a force on the shield in a first direction by expanding and exerting force on any adjacent structures in a second direction, which may be orthogonal to the first direction. Suitable compliant, conductive materials

6

to make at least a portion of the shield include elastomers filled with conductive particles.

Exerting force in at least two orthogonal directions when the shield is compressed enables the shield to press against, and therefore make electrical connection to, conducting pads on a surface of the printed circuit board and to conducting elements extending from the connector. Those extending structures may have a surface that is orthogonal to the surface of the printed circuit board. By contacting the extending conducting element on a surface provides a wide area over which contact is made, improving performance of the connector relative to contacting the shield along an edge of the extending conducting element.

To provide mechanical support for the compliant conductive material, as well as other structures, the compliant shield may include an insulative member. The insulative member may have a first portion, which may be generally planar and shaped, on one surface, the fit against a mounting face of the connector. The opposing surface of the insulative member may have a plurality of raised portions, forming islands extending from the first portion. Those islands may have walls, and the compliant conductive material may occupy the space between the walls. The extending conducting elements may be disposed adjacent to the walls such that, when the compliant conductive material is compressed, it expands outwards towards the walls, pressing against the extending conducting elements. The extending conductive elements may be backed and mechanically supported by the walls.

The islands may provide insulative regions of the shield through which signal conductors may pass without being connected to ground through contact with the compliant conductive material. In some embodiments, the islands may be formed of a material that has a dielectric constant that establishes a desired impedance for the signal conductors in the mounting interface of the connector. In some embodiments, the relative dielectric constant may be 3.0 or above. In some embodiments, the relative dielectric constant may be higher, such as 3.4 or above. In some embodiments, the relative dielectric constant of at least the islands may be 3.5 or above, 3.6 or above, 3.7 or above, 3.8 or above, 3.9 or above, or 4.0 or above. Such relative dielectric constants may be achieved by selection of a binder material in combination with a filler. Known materials may be selected to provide a relative dielectric constant of up to 4.5, for example. In some embodiments, the relative dielectric constant may be up to 4.4, up to 4.3, up to 4.2, up to 4.1 or up to 4.0. Relative dielectric constants in these ranges may lead to a higher dielectric constant for the islands than for the insulative housing of the connector. The islands may have a relative dielectric constant that is, in some embodiments, at least 0.1, 0.2, 0.3, 0.4, 0.5 or 0.6 higher than the connector housing. In some embodiments the difference in relative dielectric constant will be in the range of 0.1 to 0.3, or 0.2 to 0.5, or 0.3 to 1.0.

In other embodiments, current paths between the shields within the connector and ground structures in the printed circuit board may be created by contact tails extending from the internal connector shields engaging a compliant shield that engages conductive pads on the printed circuit board. The compliant shield may include a conductive body portion and a plurality of compliant fingers attached to and extending from the conductive body portion. Such a compliant shield may be formed from a sheet of conductive material.

In accordance with some embodiments, the compliant shield may include a conductive body portion and a plurality of compliant members. The compliant members may

attached to and extend from the conductive body portion. The compliant members may be in the form of compliant fingers or any other suitable shapes. The conductive body portion may be electrically connected to surface pads on the printed circuit board. The surface pads, in turn, may be connected to inner ground layers of the printed circuit boards through vias receiving contact tails from the connector plus shadow vias.

The compliant shield may be made of a material with desired conductivity for the current paths. The material may also be suitably springy such that fingers cut out of the material generate a sufficient force to make a reliable electrical connection to the surface pads of the printed circuit board and/or to conductive structures extending from the connector. Suitable compliant, conductive materials to make at least a portion of the compliant shield include metals, metal alloys, superelastic and shape memory materials. Superelastic materials and shape memory materials are described in co-pending U.S. Pre-grant Publication 2016-0308296, which is hereby incorporated by reference in its entirety.

Electrical connection through the compliant shield may be facilitated by compliance of the shield such that the shield may be compressed when the connector is mounted to the printed circuit board. Compliance may enable the shield to generate force against the printed circuit board, regardless of variations in separation that may occur as a result of manufacturing tolerances. In embodiments in which compliance is generated by deflection of fingers cut from a sheet of metal, the fingers may be, in an uncompressed state, bent out of the plane of the sheet by an amount equal to the tolerance in positioning a mounting face of the connector against an upper surface of the printed circuit board.

The compliance of the shield may be provided by the resilient fingers, which can deform to accommodate manufacturing variations in separation between the board and the connector. The fingers may extend from a sheet of metal positioned between the connector and the printed circuit board. However, in some embodiments, the fingers may extend from internal shields or ground structures of the connector, passing through and making electrical contact with a metal component between the mounting face of the connector housing and an upper surface of the printed circuit board.

In some embodiments, the shadow vias may be positioned adjacent the distal ends of the fingers extending from the compliant shield. Those fingers may be adjacent to contact tails of signal conductors extending from the connector. In some embodiments, a proximal end of the fingers may be attached to a body of the shield. The shield may be configured to engage ground contact tails, tabs or other conductive structures extending from shields within the connector. Accordingly, a suitably positioned current flow path may exist through shields inside the connector, through the compliant shields, into the pads on the surface of the printed circuit board and to the inner ground layers of the printed circuit board through shadow vias.

FIG. 1 illustrates an electrical interconnection system of the form that may be used in an electronic system. In this example, the electrical interconnection system includes a right angle connector and may be used, for example, in electrically connecting a daughtercard to a backplane. These figures illustrate two mating connectors. In this example, connector **200** is designed to be attached to a backplane and connector **600** is designed to attach to a daughtercard. As can be seen in FIG. 1, daughtercard connector **600** includes contact tails **610** designed to attach to a daughtercard (not

shown). Backplane connector **200** includes contact tails **210**, designed to attach to a backplane (not shown). These contact tails form one end of conductive elements that pass through the interconnection system. When the connectors are mounted to printed circuit boards, these contact tails will make electrical connection to conductive structures within the printed circuit board that carry signals or are connected to a reference potential. In the example illustrated the contact tails are press fit, “eye of the needle,” contacts that are designed to be pressed into vias in a printed circuit board. However, other forms of contact tails may be used.

Each of the connectors also has a mating interface where that connector can mate—or be separated from—the other connector. Daughtercard connector **600** includes a mating interface **620**. Backplane connector **200** includes a mating interface **220**. Though not fully visible in the view shown in FIG. 1, mating contact portions of the conductive elements are exposed at the mating interface.

Each of these conductive elements includes an intermediate portion that connects a contact tail to a mating contact portion. The intermediate portions may be held within a connector housing, at least a portion of which may be dielectric so as to provide electrical isolation between conductive elements. Additionally, the connector housings may include conductive or lossy portions, which in some embodiments may provide conductive or partially conductive paths between some of the conductive elements. In some embodiments, the conductive portions may provide shielding. The lossy portions may also provide shielding in some instances and/or may provide desirable electrical properties within the connectors.

In various embodiments, dielectric members may be molded or over-molded from a dielectric material such as plastic or nylon. Examples of suitable materials include, but are not limited to, liquid crystal polymer (LCP), polyphenylene sulfide (PPS), high temperature nylon or polyphenylenoxide (PPO) or polypropylene (PP). Other suitable materials may be employed, as aspects of the present disclosure are not limited in this regard.

All of the above-described materials are suitable for use as binder material in manufacturing connectors. In accordance some embodiments, one or more fillers may be included in some or all of the binder material. As a non-limiting example, thermoplastic PPS filled to 30% by volume with glass fiber may be used to form the entire connector housing or dielectric portions of the housings.

Alternatively or additionally, portions of the housings may be formed of conductive materials, such as machined metal or pressed metal powder. In some embodiments, portions of the housing may be formed of metal or other conductive material with dielectric members spacing signal conductors from the conductive portions. In the embodiment illustrated, for example, a housing of backplane connector **200** may have regions formed of a conductive material with insulative members separating the intermediate portions of signal conductors from the conductive portions of the housing.

The housing of daughtercard connector **600** may also be formed in any suitable way. In the embodiment illustrated, daughtercard connector **600** may be formed from multiple subassemblies, referred to herein as “wafers.” Each of the wafers (**700**, FIG. 7) may include a housing portion, which may similarly include dielectric, lossy and/or conductive portions. One or more members may hold the wafers in a desired position. For example, support members **612** and **614** may hold top and rear portions, respectively, of multiple wafers in a side-by-side configuration. Support members

612 and **614** may be formed of any suitable material, such as a sheet of metal stamped with tabs, openings or other features that engage corresponding features on the individual wafers.

Other members that may form a portion of the connector housing may provide mechanical integrity for daughtercard connector **600** and/or hold the wafers in a desired position. For example, a front housing portion **640** (FIG. **6**) may receive portions of the wafers forming the mating interface. Any or all of these portions of the connector housing may be

dielectric, lossy and/or conductive, to achieve desired electrical properties for the interconnection system. In some embodiments, each wafer may hold a column of conductive elements forming signal conductors. These signal conductors may be shaped and spaced to form single ended signal conductors. However, in the embodiment illustrated in FIG. **1**, the signal conductors are shaped and spaced in pairs to provide differential signal conductors. Each of the columns may include or be bounded by conductive elements serving as ground conductors. It should be appreciated that ground conductors need not be connected to earth ground, but are shaped to carry reference potentials, which may include earth ground, DC voltages or other suitable reference potentials. The “ground” or “reference” conductors may have a shape different than the signal conductors, which are configured to provide suitable signal transmission properties for high frequency signals.

Conductive elements may be made of metal or any other material that is conductive and provides suitable mechanical properties for conductive elements in an electrical connector. Phosphor-bronze, beryllium copper and other copper alloys are non-limiting examples of materials that may be used. The conductive elements may be formed from such materials in any suitable way, including by stamping and/or forming.

The spacing between adjacent columns of conductors may be within a range that provides a desirable density and desirable signal integrity. As a non-limiting example, the conductors may be stamped from 0.4 mm thick copper alloy, and the conductors within each column may be spaced apart by 2.25 mm and the columns of conductors may be spaced apart by 2.4 mm. However, a higher density may be achieved by placing the conductors closer together. In other embodiments, for example, smaller dimensions may be used to provide higher density, such as a thickness between 0.2 and 0.4 mm or spacing of 0.7 to 1.85 mm between columns or between conductors within a column. Moreover, each column may include four pairs of signal conductors, such that a density of 60 or more pairs per linear inch is achieved for the interconnection system illustrated in FIG. **1**. However, it should be appreciated that more pairs per column, tighter spacing between pairs within the column and/or smaller distances between columns may be used to achieve a higher density connector.

The wafers may be formed any suitable way. In some embodiments, the wafers may be formed by stamping columns of conductive elements from a sheet of metal and over molding dielectric portions on the intermediate portions of the conductive elements. In other embodiments, wafers may be assembled from modules each of which includes a single, single-ended signal conductor, a single pair of differential signal conductors or any suitable number of single ended or differential pairs.

Assembling wafers from modules may aid in reducing “skew” in signal pairs at higher frequencies, such as between about 25 GHz and 40 GHz, or higher. Skew, in this context, refers to the difference in electrical propagation time

between signals of a pair that operates as a differential signal. Modular construction that reduces skew is designed described, for example in application 61/930,411, which is incorporated herein by reference.

In accordance with techniques described in that co-pending application, in some embodiments, connectors may be formed of modules, each carrying a signal pair. The modules may be individually shielded, such as by attaching shield members to the modules and/or inserting the modules into an organizer or other structure that may provide electrical shielding between pairs and/or ground structures around the conductive elements carrying signals.

In some embodiments, signal conductor pairs within each module may be broadside coupled over substantial portions of their lengths. Broadside coupling enables the signal conductors in a pair to have the same physical length. To facilitate routing of signal traces within the connector footprint of a printed circuit board to which a connector is attached and/or constructing of mating interfaces of the connectors, the signal conductors may be aligned with edge to edge coupling in one or both of these regions. As a result, the signal conductors may include transition regions in which coupling changes from edge-to-edge to broadside or vice versa. As described below, these transition regions may be designed to prevent mode conversion or suppress undesired propagation modes that can interfere with signal integrity of the interconnection system.

The modules may be assembled into wafers or other connector structures. In some embodiments, a different module may be formed for each row position at which a pair is to be assembled into a right angle connector. These modules may be made to be used together to build up a connector with as many rows as desired. For example, a module of one shape may be formed for a pair to be positioned at the shortest rows of the connector, sometimes called the a-b rows. A separate module may be formed for conductive elements in the next longest rows, sometimes called the c-d rows. The inner portion of the module with the c-d rows may be designed to conform to the outer portion of the module with the a-b rows.

This pattern may be repeated for any number of pairs. Each module may be shaped to be used with modules that carry pairs for shorter and/or longer rows. To make a connector of any suitable size, a connector manufacturer may assemble into a wafer a number of modules to provide a desired number of pairs in the wafer. In this way, a connector manufacturer may introduce a connector family for a widely used connector size—such as 2 pairs. As customer requirements change, the connector manufacturer may procure tools for each additional pair, or, for modules that contain multiple pairs, group of pairs to produce connectors of larger sizes. The tooling used to produce modules for smaller connectors can be used to produce modules for the shorter rows even of the larger connectors. Such a modular connector is illustrated in FIG. **8**.

Further details of the construction of the interconnection system of FIG. **1** are provided in FIG. **2**, which shows backplane connector **200** partially cutaway. In the embodiment illustrated in FIG. **2**, a forward wall of housing **222** is cut away to reveal the interior portions of mating interface **220**.

In the embodiment illustrated, backplane connector **200** also has a modular construction. Multiple pin modules **300** are organized to form an array of conductive elements. Each of the pin modules **300** may be designed to mate with a module of daughtercard connector **600**.

11

In the embodiment illustrated, four rows and eight columns of pin modules **300** are shown. With each pin module having two signal conductors, the four rows **230A**, **230B**, **230C** and **230D** of pin modules create columns with four pairs or eight signal conductors, in total. It should be appreciated, however, that the number of signal conductors per row or column is not a limitation of the invention. A greater or lesser number of rows of pin modules may be included within housing **222**. Likewise, a greater or lesser number of columns may be included within housing **222**. Alternatively or additionally, housing **222** may be regarded as a module of a backplane connector, and multiple such modules may be aligned side to side to extend the length of a backplane connector.

In the embodiment illustrated in FIG. 2, each of the pin modules **300** contains conductive elements serving as signal conductors. Those signal conductors are held within insulative members, which may serve as a portion of the housing of backplane connector **200**. The insulative portions of the pin modules **300** may be positioned to separate the signal conductors from other portions of housing **222**. In this configuration, other portions of housing **222** may be conductive or partially conductive, such as may result from the use of lossy materials.

In some embodiments, housing **222** may contain both conductive and lossy portions. For example, a shroud including walls **226** and a floor **228** may be pressed from a powdered metal or formed from conductive material in any other suitable way. Pin modules **300** may be inserted into openings within floor **228**.

Lossy or conductive members may be positioned adjacent rows **230A**, **230B**, **230C** and **230D** of pin modules **300**. In the embodiment of FIG. 2, separators **224A**, **224B** and **224C** are shown between adjacent rows of pin modules. Separators **224A**, **224B** and **224C** may be conductive or lossy, and may be formed as part of the same operation or from the same member that forms walls **226** and floor **228**. Alternatively, separators **224A**, **224B** and **224C** may be inserted separately into housing **222** after walls **226** and floor **228** are formed. In embodiments in which separators **224A**, **224B** and **224C** formed separately from walls **226** and floor **228** and subsequently inserted into housing **222**, separators **224A**, **224B** and **224C** may be formed of a different material than walls **226** and/or floor **228**. For example, in some embodiments, walls **226** and floor **228** may be conductive while separators **224A**, **224B** and **224C** may be lossy or partially lossy and partially conductive.

In some embodiments, other lossy or conductive members may extend into mating interface **220**, perpendicular to floor **228**. Members **240** are shown adjacent to end-most rows **230A** and **230D**. In contrast to separators **224A**, **224B** and **224C**, which extend across the mating interface **220**, separator members **240**, approximately the same width as one column, are positioned in rows adjacent row **230A** and row **230D**. Daughtercard connector **600** may include, in its mating interface **620**, slots to receive, separators **224A**, **224B** and **224C**. Daughtercard connector **600** may include openings that similarly receive members **240**. Members **240** may have a similar electrical effect to separators **224A**, **224B** and **224C**, in that both may suppress resonances, crosstalk or other undesired electrical effects. Members **240**, because they fit into smaller openings within daughtercard connector **600** than separators **224A**, **224B** and **224C**, may enable greater mechanical integrity of housing portions of daughtercard connector **600** at the sides where members **240** are received.

12

FIG. 3 illustrates a pin module **300** in greater detail. In this embodiment, each pin module includes a pair of conductive elements acting as signal conductors **314A** and **314B**. Each of the signal conductors has a mating interface portion shaped as a pin. Opposing ends of the signal conductors have contact tails **316A** and **316B**. In this embodiment, the contact tails are shaped as press fit compliant sections. Intermediate portions of the signal conductors, connecting the contact tails to the mating contact portions, pass through pin module **300**.

Conductive elements serving as reference conductors **320A** and **320B** are attached at opposing exterior surfaces of pin module **300**. Each of the reference conductors has contact tails **328**, shaped for making electrical connections to vias within a printed circuit board. The reference conductors also have mating contact portions. In the embodiment illustrated, two types of mating contact portions are illustrated. Compliant member **322** may serve as a mating contact portion, pressing against a reference conductor in daughtercard connector **600**. In some embodiments, surfaces **324** and **326** alternatively or additionally may serve as mating contact portions, where reference conductors from the mating conductor may press against reference conductors **320A** or **320B**. However, in the embodiment illustrated, the reference conductors may be shaped such that electrical contact is made only at compliant member **322**.

FIG. 4 shows an exploded view of pin module **300**. Intermediate portions of the signal conductors **314A** and **314B** are held within an insulative member **410**, which may form a portion of the housing of backplane connector **200**. Insulative member **410** may be insert molded around signal conductors **314A** and **314B**. A surface **412** against which reference conductor **320B** presses is visible in the exploded view of FIG. 4. Likewise, the surface **428** of reference conductor **320A**, which presses against a surface of member **410** not visible in FIG. 4, can also be seen in this view.

As can be seen, the surface **428** is substantially unbroken. Attachment features, such as tab **432** may be formed in the surface **428**. Such a tab may engage an opening (not visible in the view shown in FIG. 4) in insulative member **410** to hold reference conductor **320A** to insulative member **410**. A similar tab (not numbered) may be formed in reference conductor **320B**. As shown, these tabs, which serve as attachment mechanisms, are centered between signal conductors **314A** and **314B** where radiation from or affecting the pair is relatively low. Additionally, tabs, such as **436**, may be formed in reference conductors **320A** and **320B**. Tabs **436** may engage insulative member **410** to hold pin module **300** in an opening in floor **228**.

In the embodiment illustrated, compliant member **322** is not cut from the planar portion of the reference conductor **320B** that presses against the surface **412** of the insulative member **410**. Rather, compliant member **322** is formed from a different portion of a sheet of metal and folded over to be parallel with the planar portion of the reference conductor **320B**. In this way, no opening is left in the planar portion of the reference conductor **320B** from forming compliant member **322**. Moreover, as shown, compliant member **322** has two compliant portions **424A** and **424B**, which are joined together at their distal ends but separated by an opening **426**. This configuration may provide mating contact portions with a suitable mating force in desired locations without leaving an opening in the shielding around pin module **300**. However, a similar effect may be achieved in some embodiments by attaching separate compliant members to reference conductors **320A** and **320B**.

The reference conductors **320A** and **320B** may be held to pin module **300** in any suitable way. As noted above, tabs **432** may engage an opening **434** in the housing portion. Additionally or alternatively, straps or other features may be used to hold other portions of the reference conductors. As shown each reference conductor includes straps **430A** and **430B**. Straps **430A** include tabs while straps **430B** include openings adapted to receive those tabs. Here reference conductors **320A** and **320B** have the same shape, and may be made with the same tooling, but are mounted on opposite surfaces of the pin module **300**. As a result, a tab **430A** of one reference conductor aligns with a tab **430B** of the opposing reference conductor such that the tab **430A** and the tab **430B** interlock and hold the reference conductors in place. These tabs may engage in an opening **448** in the insulative member, which may further aid in holding the reference conductors in a desired orientation relative to signal conductors **314A** and **314B** in pin module **300**.

FIG. **4** further reveals a tapered surface **450** of the insulative member **410**. In this embodiment surface **450** is tapered with respect to the axis of the signal conductor pair formed by signal conductors **314A** and **314B**. Surface **450** is tapered in the sense that it is closer to the axis of the signal conductor pair closer to the distal ends of the mating contact portions and further from the axis further from the distal ends. In the embodiment illustrated, pin module **300** is symmetrical with respect to the axis of the signal conductor pair and a tapered surface **450** is formed adjacent each of the signal conductors **314A** and **314B**.

In accordance with some embodiments, some or all of the adjacent surfaces in mating connectors may be tapered. Accordingly, though not shown in FIG. **4**, surfaces of the insulative portions of daughtercard connector **600** that are adjacent to tapered surfaces **450** may be tapered in a complementary fashion such that the surfaces from the mating connectors conform to one another when the connectors are in the designed mating positions.

Tapered surfaces in the mating interfaces may avoid abrupt changes in impedance as a function of connector separation. Accordingly, other surfaces designed to be adjacent a mating connector may be similarly tapered. FIG. **4** shows such tapered surfaces **452**. As shown, tapered surfaces **452** are between signal conductors **314A** and **314B**. Surfaces **450** and **452** cooperate to provide a taper on the insulative portions on both sides of the signal conductors.

FIG. **5** shows further detail of pin module **300**. Here, the signal conductors are shown separated from the pin module. FIG. **5** illustrates the signal conductors before being overmolded by insulative portions or otherwise being incorporated into a pin module **300**. However, in some embodiments, the signal conductors may be held together by a carrier strip or other suitable support mechanism, not shown in FIG. **5**, before being assembled into a module.

In the illustrated embodiment, the signal conductors **314A** and **314B** are symmetrical with respect to an axis **500** of the signal conductor pair. Each has a mating contact portion, **510A** or **510B** shaped as a pin. Each also has an intermediate portion **512A** or **512B**, and **514A** or **514B**. Here, different widths are provided to provide for matching impedance to a mating connector and a printed circuit board, despite different materials or construction techniques in each. A transition region may be included, as illustrated, to provide a gradual transition between regions of different width. Contact tails **516A** or **516B** may also be included.

In the embodiment illustrated, intermediate portions **512A**, **512B**, **514A** and **514B** may be flat, with broadsides and narrower edges. The signal conductors of the pairs are,

in the embodiment illustrated, aligned edge-to-edge and are thus configured for edge coupling. In other embodiments, some or all of the signal conductor pairs may alternatively be broadside coupled.

Mating contact portions may be of any suitable shape, but in the embodiment illustrated, they are cylindrical. The cylindrical portions may be formed by rolling portions of a sheet of metal into a tube or in any other suitable way. Such a shape may be created, for example, by stamping a shape from a sheet of metal that includes the intermediate portions. A portion of that material may be rolled into a tube to provide the mating contact portion. Alternatively or additionally, a wire or other cylindrical element may be flattened to form the intermediate portions, leaving the mating contact portions cylindrical. One or more openings (not numbered) may be formed in the signal conductors. Such openings may ensure that the signal conductors are securely engaged with the insulative member **410**.

Turning to FIG. **6**, further details of daughtercard connector **600** are shown in a partially exploded view. As shown, connector **600** includes multiple wafers **700A** held together in a side-by-side configuration. Here, eight wafers, corresponding to the eight columns of pin modules in backplane connector **200**, are shown. However, as with backplane connector **200**, the size of the connector assembly may be configured by incorporating more rows per wafer, more wafers per connector or more connectors per interconnection system.

Conductive elements within the wafers **700A** may include mating contact portions and contact tails. Contact tails **610** are shown extending from a surface of connector **600** adapted for mounting against a printed circuit board. In some embodiments, contact tails **610** may pass through a member **630**. Member **630** may include insulative, lossy or conductive portions. In some embodiments, contact tails associated with signal conductors may pass through insulative portions of member **630**. Contact tails associated with reference conductors may pass through lossy or conductive portions of member **630**.

Mating contact portions of the wafers **700A** are held in a front housing portion **640**. The front housing portion may be made of any suitable material, which may be insulative, lossy or conductive or may include any suitable combination or such materials. For example the front housing portion may be molded from a filled, lossy material or may be formed from a conductive material, using materials and techniques similar to those described above for the housing walls **226**. As shown, the wafers are assembled from modules **810A**, **810B**, **810C** and **810D** (FIG. **8**), each with a pair of signal conductors surrounded by reference conductors. In the embodiment illustrated, front housing portion **640** has multiple passages, each positioned to receive one such pair of signal conductors and associated reference conductors. However, it should be appreciated that each module might contain a single signal conductor or more than two signal conductors.

FIG. **7** illustrates a wafer **700**. Multiple such wafers may be aligned side-by-side and held together with one or more support members, or in any other suitable way, to form a daughtercard connector. In the embodiment illustrated, wafer **700** is formed from multiple modules **810A**, **810B**, **810C** and **810D**. The modules are aligned to form a column of mating contact portions along one edge of wafer **700** and a column of contact tails along another edge of wafer **700**. In the embodiment in which the wafer is designed for use in a right angle connector, as illustrated, those edges are perpendicular.

In the embodiment illustrated, each of the modules includes reference conductors that at least partially enclose the signal conductors. The reference conductors may similarly have mating contact portions and contact tails.

The modules may be held together in any suitable way. For example, the modules may be held within a housing, which in the embodiment illustrated is formed with members **900A** and **900B**. Members **900A** and **900B** may be formed separately and then secured together, capturing modules **810A** . . . **810D** between them. Members **900A** and **900B** may be held together in any suitable way, such as by attachment members that form an interference fit or a snap fit. Alternatively or additionally, adhesive, welding or other attachment techniques may be used.

Members **900A** and **900B** may be formed of any suitable material. That material may be an insulative material. Alternatively or additionally, that material may be or may include portions that are lossy or conductive. Members **900A** and **900B** may be formed, for example, by molding such materials into a desired shape. Alternatively, members **900A** and **900B** may be formed in place around modules **810A** . . . **810D**, such as via an insert molding operation. In such an embodiment, it is not necessary that members **900A** and **900B** be formed separately. Rather, a housing portion to hold modules **810A** . . . **810D** may be formed in one operation.

FIG. **8** shows modules **810A** . . . **810D** without members **900A** and **900B**. In this view, the reference conductors are visible. Signal conductors (not visible in FIG. **8**) are enclosed within the reference conductors, forming a waveguide structure. Each waveguide structure includes a contact tail region **820**, an intermediate region **830** and a mating contact region **840**. Within the mating contact region **840** and the contact tail region **820**, the signal conductors are positioned edge to edge. Within the intermediate region **830**, the signal conductors are positioned for broadside coupling. Transition regions **822** and **842** are provided to transition between the edge coupled orientation and the broadside coupled orientation.

The transition regions **822** and **842** in the reference conductors may correspond to transition regions in signal conductors, as described below. In the illustrated embodiment, reference conductors form an enclosure around the signal conductors. A transition region in the reference conductors, in some embodiments, may keep the spacing between the signal conductors and reference conductors generally uniform over the length of the signal conductors. Thus, the enclosure formed by the reference conductors may have different widths in different regions.

The reference conductors provide shielding coverage along the length of the signal conductors. As shown, coverage is provided over substantially all of the length of the signal conductors, with coverage in the mating contact portion and the intermediate portions of the signal conductors. The contact tails are shown exposed so that they can make contact with the printed circuit board. However, in use, these mating contact portions will be adjacent ground structures within a printed circuit board such that being exposed as shown in FIG. **8** does not detract from shielding coverage along substantially all of the length of the signal conductor. In some embodiments, mating contact portions might also be exposed for mating to another connector. Accordingly, in some embodiments, shielding coverage may be provided over more than 80%, 85%, 90% or 95% of the intermediate portion of the signal conductors. Similarly shielding coverage may also be provided in the transition regions, such that shielding coverage may be provided over more than 80%, 85%, 90% or 95% of the combined length of the interme-

mediate portion and transition regions of the signal conductors. In some embodiments, as illustrated, the mating contact regions and some or all of the contact tails may also be shielded, such that shielding coverage may be, in various embodiments, over more than 80%, 85%, 90% or 95% of the length of the signal conductors.

In the embodiment illustrated, a waveguide-like structure formed by the reference conductors has a wider dimension in the column direction of the connector in the contact tail regions **820** and the mating contact region **840** to accommodate for the wider dimension of the signal conductors being side-by-side in the column direction in these regions. In the embodiment illustrated, contact tail regions **820** and the mating contact region **840** of the signal conductors are separated by a distance that aligns them with the mating contacts of a mating connector or contact structures on a printed circuit board to which the connector is to be attached.

These spacing requirements mean that the waveguide will be wider in the column dimension than it is in the transverse direction, providing an aspect ratio of the waveguide in these regions that may be at least 2:1, and in some embodiments may be on the order of at least 3:1. Conversely, in the intermediate region **830**, the signal conductors are oriented with the wide dimension of the signal conductors overlaid in the column dimension, leading to an aspect ratio of the waveguide that may be less than 2:1, and in some embodiments may be less than 1.5:1 or on the order of 1:1.

With this smaller aspect ratio, the largest dimension of the waveguide in the intermediate region **830** will be smaller than the largest dimension of the waveguide in regions **830** and **840**. Because that the lowest frequency propagated by a waveguide is inversely proportional to the length of its shortest dimension, the lowest frequency mode of propagation that can be excited in intermediate region **830** is higher than can be excited in contact tail regions **820** and the mating contact region **840**. The lowest frequency mode that can be excited in the transition regions will be intermediate between the two. Because the transition from edge coupled to broadside coupling has the potential to excite undesired modes in the waveguides, signal integrity may be improved if these modes are at higher frequencies than the intended operating range of the connector, or at least are as high as possible.

These regions may be configured to avoid mode conversion upon transition between coupling orientations, which would excite propagation of undesired signals through the waveguides. For example, as shown below, the signal conductors may be shaped such that the transition occurs in the intermediate region **830** or the transition regions **822** and **842**, or partially within both. Additionally or alternatively, the modules may be structured to suppress undesired modes excited in the waveguide formed by the reference conductors, as described in greater detail below.

Though the reference conductors may substantially enclose each pair, it is not a requirement that the enclosure be without openings. Accordingly, in embodiments shaped to provide rectangular shielding, the reference conductors in the intermediate regions may be aligned with at least portions of all four sides of the signal conductors. The reference conductors may combine for example to provide 360 degree coverage around the pair of signal conductors. Such coverage may be provided, for example, by overlapping or physically contact reference conductors. In the illustrated embodiment, the reference conductors are U-shaped shells and come together to form an enclosure.

Three hundred sixty degree coverage may be provided regardless of the shape of the reference conductors. For example, such coverage may be provided with circular, elliptical or reference conductors of any other suitable shape. However, it is not a requirement that the coverage be complete. The coverage, for example, may have an angular extent in the range between about 270 and 365 degrees. In some embodiments, the coverage may be in the range of about 340 to 360 degrees. Such coverage may be achieved for example, by slots or other openings in the reference conductors.

In some embodiments, the shielding coverage may be different in different regions. In the transition regions, the shielding coverage may be greater than in the intermediate regions. In some embodiments, the shielding coverage may have an angular extent of greater than 355 degrees, or even in some embodiments 360 degrees, resulting from direct contact, or even overlap, in reference conductors in the transition regions even if less shielding coverage is provided in the transition regions.

The inventors have recognized and appreciated that, in some sense, fully enclosing a signal pair in reference conductors in the intermediate regions may create effects that undesirably impact signal integrity, particularly when used in connection with a transition between edge coupling and broadside coupling within a module. The reference conductors surrounding the signal pair may form a waveguide. Signals on the pair, and particularly within a transition region between edge coupling and broadside coupling, may cause energy from the differential mode of propagation between the edges to excite signals that can propagate within the waveguide. In accordance with some embodiments, one or more techniques to avoid exciting these undesired modes, or to suppress them if they are excited, may be used.

Some techniques that may be used to increase the frequency that will excite the undesired modes. In the embodiment illustrated, the reference conductors may be shaped to leave openings **832**. These openings may be in the narrower wall of the enclosure. However, in embodiments in which there is a wider wall, the openings may be in the wider wall. In the embodiment illustrated, openings **832** run parallel to the intermediate portions of the signal conductors and are between the signal conductors that form a pair. These slots lower the angular extent of the shielding, such that, adjacent the broadside coupled intermediate portions of the signal conductors, the angular extent of the shielding may be less than 360 degrees. It may, for example, be in the range of 355 of less. In embodiments in which members **900A** and **900B** are formed by over molding lossy material on the modules, lossy material may be allowed to fill openings **832**, with or without extending into the inside of the waveguide, which may suppress propagation of undesired modes of signal propagation, that can decrease signal integrity.

In the embodiment illustrated in FIG. **8**, openings **832** are slot shaped, effectively dividing the shielding in half in intermediate region **830**. The lowest frequency that can be excited in a structure serving as a waveguide, as is the effect of the reference conductors that substantially surround the signal conductors as illustrated in FIG. **8**, is inversely proportional to the dimensions of the sides. In some embodiments, the lowest frequency waveguide mode that can be excited is a TEM mode. Effectively shortening a side by incorporating slot-shaped opening **832**, raises the frequency of the TEM mode that can be excited. A higher resonant frequency can mean that less energy within the operating frequency range of the connector is coupled into undesired

propagation within the waveguide formed by the reference conductors, which improves signal integrity.

In region **830**, the signal conductors of a pair are broadside coupled and the openings **832**, with or without lossy material in them, may suppress TEM common modes of propagation. While not being bound by any particular theory of operation, the inventors theorize that openings **832**, in combination with an edge coupled to broadside coupled transition, aids in providing a balanced connector suitable for high frequency operation.

FIG. **9** illustrates a member **900**, which may be a representation of member **900A** or **900B**. As can be seen, member **900** is formed with channels **910A** . . . **910D** shaped to receive modules **810A** . . . **810D** shown in FIG. **8**. With the modules in the channels, member **900A** may be secured to member **900B**. In the illustrated embodiment, attachment of members **900A** and **900B** may be achieved by posts, such as post **920**, in one member, passing through a hole, such as hole **930**, in the other member. The post may be welded or otherwise secured in the hole. However, any suitable attachment mechanism may be used.

Members **900A** and **900B** may be molded from or include a lossy material. Any suitable lossy material may be used for these and other structures that are “lossy.” Materials that conduct, but with some loss, or material which by another physical mechanism absorbs electromagnetic energy over the frequency range of interest are referred to herein generally as “lossy” materials. Electrically lossy materials can be formed from lossy dielectric and/or poorly conductive and/or lossy magnetic materials. Magnetically lossy material can be formed, for example, from materials traditionally regarded as ferromagnetic materials, such as those that have a magnetic loss tangent greater than approximately 0.05 in the frequency range of interest. The “magnetic loss tangent” is the ratio of the imaginary part to the real part of the complex electrical permeability of the material. Practical lossy magnetic materials or mixtures containing lossy magnetic materials may also exhibit useful amounts of dielectric loss or conductive loss effects over portions of the frequency range of interest. Electrically lossy material can be formed from material traditionally regarded as dielectric materials, such as those that have an electric loss tangent greater than approximately 0.05 in the frequency range of interest. The “electric loss tangent” is the ratio of the imaginary part to the real part of the complex electrical permittivity of the material. Electrically lossy materials can also be formed from materials that are generally thought of as conductors, but are either relatively poor conductors over the frequency range of interest, contain conductive particles or regions that are sufficiently dispersed that they do not provide high conductivity or otherwise are prepared with properties that lead to a relatively weak bulk conductivity compared to a good conductor such as copper over the frequency range of interest.

Electrically lossy materials typically have a bulk conductivity of about 1 Siemen/meter to about 10,000 Siemens/meter and preferably about 1 siemen/meter to about 5,000 Siemens/meter. In some embodiments material with a bulk conductivity of between about 10 Siemens/meter and about 200 Siemens/meter may be used. As a specific example, material with a conductivity of about 50 Siemens/meter may be used. However, it should be appreciated that the conductivity of the material may be selected empirically or through electrical simulation using known simulation tools to determine a suitable conductivity that provides a suitably low crosstalk with a suitably low signal path attenuation or insertion loss.

Electrically lossy materials may be partially conductive materials, such as those that have a surface resistivity between 1 Ω /square and 100,000 Ω /square. In some embodiments, the electrically lossy material has a surface resistivity between 10 Ω /square and 1000 Ω /square. As a specific example, the material may have a surface resistivity of between about 20 Ω /square and 80 Ω /square.

In some embodiments, electrically lossy material is formed by adding to a binder a filler that contains conductive particles. In such an embodiment, a lossy member may be formed by molding or otherwise shaping the binder with filler into a desired form. Examples of conductive particles that may be used as a filler to form an electrically lossy material include carbon or graphite formed as fibers, flakes, nanoparticles, or other types of particles. Metal in the form of powder, flakes, fibers or other particles may also be used to provide suitable electrically lossy properties. Alternatively, combinations of fillers may be used. For example, metal plated carbon particles may be used. Silver and nickel are suitable metal plating for fibers. Coated particles may be used alone or in combination with other fillers, such as carbon flake. The binder or matrix may be any material that will set, cure, or can otherwise be used to position the filler material. In some embodiments, the binder may be a thermoplastic material traditionally used in the manufacture of electrical connectors to facilitate the molding of the electrically lossy material into the desired shapes and locations as part of the manufacture of the electrical connector. Examples of such materials include liquid crystal polymer (LCP) and nylon. However, many alternative forms of binder materials may be used. Curable materials, such as epoxies, may serve as a binder. Alternatively, materials such as thermosetting resins or adhesives may be used.

Also, while the above described binder materials may be used to create an electrically lossy material by forming a binder around conducting particle fillers, the invention is not so limited. For example, conducting particles may be impregnated into a formed matrix material or may be coated onto a formed matrix material, such as by applying a conductive coating to a plastic component or a metal component. As used herein, the term "binder" encompasses a material that encapsulates the filler, is impregnated with the filler or otherwise serves as a substrate to hold the filler.

Preferably, the fillers will be present in a sufficient volume percentage to allow conducting paths to be created from particle to particle. For example, when metal fiber is used, the fiber may be present in about 3% to 40% by volume. The amount of filler may impact the conducting properties of the material.

Filled materials may be purchased commercially, such as materials sold under the trade name Celestran® by Celanese Corporation which can be filled with carbon fibers or stainless steel filaments. A lossy material, such as lossy conductive carbon filled adhesive preform, such as those sold by Techfilm of Billerica, Mass., US may also be used. This preform can include an epoxy binder filled with carbon fibers and/or other carbon particles. The binder surrounds carbon particles, which act as a reinforcement for the preform. Such a preform may be inserted in a connector wafer to form all or part of the housing. In some embodiments, the preform may adhere through the adhesive in the preform, which may be cured in a heat treating process. In some embodiments, the adhesive may take the form of a separate conductive or non-conductive adhesive layer. In some embodiments, the adhesive in the preform alterna-

tively or additionally may be used to secure one or more conductive elements, such as foil strips, to the lossy material.

Various forms of reinforcing fiber, in woven or non-woven form, coated or non-coated may be used. Non-woven carbon fiber is one suitable material. Other suitable materials, such as custom blends as sold by RTP Company, can be employed, as the present invention is not limited in this respect.

In some embodiments, a lossy member may be manufactured by stamping a preform or sheet of lossy material. For example, an insert may be formed by stamping a preform as described above with an appropriate pattern of openings. However, other materials may be used instead of or in addition to such a preform. A sheet of ferromagnetic material, for example, may be used.

However, lossy members also may be formed in other ways. In some embodiments, a lossy member may be formed by interleaving layers of lossy and conductive material such as metal foil. These layers may be rigidly attached to one another, such as through the use of epoxy or other adhesive, or may be held together in any other suitable way. The layers may be of the desired shape before being secured to one another or may be stamped or otherwise shaped after they are held together.

FIG. 10 shows further details of construction of a wafer module 1000. Module 1000 may be representative of any of the modules in a connector, such as any of the modules 810A . . . 810D shown in FIGS. 7-8. Each of the modules 810A . . . 810D may have the same general construction, and some portions may be the same for all modules. For example, the contact tail regions 820 and mating contact regions 840 may be the same for all modules. Each module may include an intermediate portion region 830, but the length and shape of the intermediate portion region 830 may vary depending on the location of the module within the wafer.

In the embodiment illustrated, module 1000 includes a pair of signal conductors 1310A and 1310B (FIG. 13) held within an insulative housing portion 1100. Insulative housing portion 1100 is enclosed, at least partially, by reference conductors 1010A and 1010B. This subassembly may be held together in any suitable way. For example, reference conductors 1010A and 1010B may have features that engage one another. Alternatively or additionally, reference conductors 1010A and 1010B may have features that engage insulative housing portion 1100. As yet another example, the reference conductors may be held in place once members 900A and 900B are secured together as shown in FIG. 7.

The exploded view of FIG. 10 reveals that mating contact region 840 includes subregions 1040 and 1042. Subregion 1040 includes mating contact portions of module 1000. When mated with a pin module 300, mating contact portions from the pin module will enter subregion 1040 and engage the mating contact portions of module 1000. These components may be dimensioned to support a "functional mating range," such that, if the module 300 and module 1000 are fully pressed together, the mating contact portions of module 1000 will slide along the pins from pin module 300 by the "functional mating range" distance during mating.

The impedance of the signal conductors in subregion 1040 will be largely defined by the structure of module 1000. The separation of signal conductors of the pair as well as the separation of the signal conductors from reference conductors 1010A and 1010B will set the impedance. The dielectric constant of the material surrounding the signal conductors, which in this embodiment is air, will also impact the impedance. In accordance with some embodiments, design

parameters of module **1000** may be selected to provide a nominal impedance within region **1040**. That impedance may be designed to match the impedance of other portions of module **1000**, which in turn may be selected to match the impedance of a printed circuit board or other portions of the interconnection system such that the connector does not create impedance discontinuities.

If the modules **300** and **1000** are in their nominal mating position, which in this embodiment is fully pressed together, the pins will be within mating contact portions of the signal conductors of module **1000**. The impedance of the signal conductors in subregion **1040** will still be driven largely by the configuration of subregion **1040**, providing a matched impedance to the rest of module **1000**.

A subregion **340** (FIG. 3) may exist within pin module **300**. In subregion **340**, the impedance of the signal conductors will be dictated by the construction of pin module **300**. The impedance will be determined by the separation of signal conductors **314A** and **314B** as well as their separation from reference conductors **320A** and **320B**. The dielectric constant of insulative portion **410** may also impact the impedance. Accordingly, these parameters may be selected to provide, within subregion **340**, an impedance, which may be designed to match the nominal impedance in subregion **1040**.

The impedance in subregions **340** and **1040**, being dictated by construction of the modules, is largely independent of any separation between the modules during mating. However, modules **300** and **1000** have, respectively, subregions **342** and **1042** that interact with components from the mating module that could influence impedance. Because the positioning of these components could influence impedance, the impedance could vary as a function of separation of the mating modules. In some embodiments, these components are positioned to reduce changes of impedance, regardless of separation distance, or to reduce the impact of changes of impedance by distributing the change across the mating region.

When pin module **300** is pressed fully against module **1000**, the components in subregions **342** and **1042** may combine to provide the nominal mating impedance. Because the modules are designed to provide functional mating range, signal conductors within pin module **300** and module **1000** may mate, even if those modules are separated by an amount that equals the functional mating range, such that separation between the modules can lead to changes in impedance, relative to the nominal value, at one or more places along the signal conductors in the mating region. Appropriate shape and positioning of these members can reduce that change or reduce the effect of the change by distributing it over portions of the mating region.

In the embodiments illustrated in FIG. 3 and FIG. 10, subregion **1042** is designed to overlap pin module **300** when module **1000** is pressed fully against pin module **300**. Projecting insulative members **1042A** and **1042B** are sized to fit within spaces **342A** and **342B**, respectively. With the modules pressed together, the distal ends of insulative members **1042A** and **1042B** press against surfaces **450** (FIG. 4). Those distal ends may have a shape complementary to the taper of surfaces **450** such that insulative members **1042A** and **1042B** fill spaces **342A** and **342B**, respectively. That overlap creates a relative position of signal conductors, dielectric, and reference conductors that may approximate the structure within subregion **340**. These components may be sized to provide the same impedance as in subregion **340** when modules **300** and **1000** are fully pressed together. When the modules are fully pressed together, which in this

example is the nominal mating position, the signal conductors will have the same impedance across the mating region made up by subregions **340**, **1040** and where subregions **342** and **1042** overlap.

These components also may be sized and may have material properties that provide impedance control as a function of separation of modules **300** and **1000**. Impedance control may be achieved by providing approximately the same impedance through subregions **342** and **1042**, even if those subregions do not fully overlap, or by providing gradual impedance transitions, regardless of separation of the modules.

In the illustrated embodiment, this impedance control is provided in part by projecting insulative members **1042A** and **1042B**, which fully or partially overlap module **300**, depending on separation between modules **300** and **1000**. These projecting insulative members can reduce the magnitude of changes in relative dielectric constant of material surrounding pins from pin module **300**. Impedance control is also provided by projections **1020A** and **1022A** and **1020B** and **1022B** in the reference conductors **1010A** and **1010B**. These projections impact the separation, in a direction perpendicular to the axis of the signal conductor pair, between portions of the signal conductor pair and the reference conductors **1010A** and **1010B**. This separation, in combination with other characteristics, such as the width of the signal conductors in those portions, may control the impedance in those portions such that it approximates the nominal impedance of the connector or does not change abruptly in a way that may cause signal reflections. Other parameters of either or both mating modules may be configured for such impedance control.

Turning to FIG. 11, further details of exemplary components of a module **1000** are illustrated. FIG. 11 is an exploded view of module **1000**, without reference conductors **1010A** and **1010B** shown. Insulative housing portion **1100** is, in the illustrated embodiment, made of multiple components. Central member **1110** may be molded from insulative material. Central member **1110** includes two grooves **1212A** and **1212B** into which conductive elements **1310A** and **1310B**, which in the illustrated embodiment form a pair of signal conductors, may be inserted.

Covers **1112** and **1114** may be attached to opposing sides of central member **1110**. Covers **1112** and **1114** may aid in holding conductive elements **1310A** and **1310B** within grooves **1212A** and **1212B** and with a controlled separation from reference conductors **1010A** and **1010B**. In the embodiment illustrated, covers **1112** and **1114** may be formed of the same material as central member **1110**. However, it is not a requirement that the materials be the same, and in some embodiments, different materials may be used, such as to provide different relative dielectric constants in different regions to provide a desired impedance of the signal conductors.

In the embodiment illustrated, grooves **1212A** and **1212B** are configured to hold a pair of signal conductors for edge coupling at the contact tails and mating contact portions. Over a substantial portion of the intermediate portions of the signal conductors, the pair is held for broadside coupling. To transition between edge coupling at the ends of the signal conductors to broadside coupling in the intermediate portions, a transition region may be included in the signal conductors. Grooves in central member **1110** may be shaped to provide the transition region in the signal conductors. Projections **1122**, **1124**, **1126** and **1128** on covers **1112** and **1114** may press the conductive elements against central portion **1110** in these transition regions.

In the embodiment illustrated in FIG. 11, it can be seen that the transition between broadside and edge coupling occurs over a region 1150. At one end of this region, the signal conductors are aligned edge-to-edge in the column direction in a plane parallel to the column direction. Traversing region 1150 in towards the intermediate portion, the signal conductors jog in opposition direction perpendicular to that plane and jog towards each other. As a result, at the end of region 1150, the signal conductors are in separate planes parallel to the column direction. The intermediate portions of the signal conductors are aligned in a direction perpendicular to those planes.

Region 1150 includes the transition region, such as 822 or 842 where the waveguide formed by the reference conductor transitions from its widest dimension to the narrower dimension of the intermediate portion, plus a portion of the narrower intermediate region 830. As a result, at least a portion of the waveguide formed by the reference conductors in this region 1150 has a widest dimension of W, the same as in the intermediate region 830. Having at least a portion of the physical transition in a narrower part of the waveguide reduces undesired coupling of energy into waveguide modes of propagation.

Having full 360 degree shielding of the signal conductors in region 1150 may also reduce coupling of energy into undesired waveguide modes of propagation. Accordingly, openings 832 do not extend into region 1150 in the embodiment illustrated.

FIG. 12 shows further detail of a module 1000. In this view, conductive elements 1310A and 1310B are shown separated from central member 1110. For clarity, covers 1112 and 1114 are not shown. Transition region 1312A between contact tail 1330A and intermediate portion 1314A is visible in this view. Similarly, transition region 1316A between intermediate portion 1314A and mating contact portion 1318A is also visible. Similar transition regions 1312 B and 1316B are visible for conductive element 1310B, allowing for edge coupling at contact tails 1330B and mating contact portions 1318B and broadside coupling at intermediate portion 1314B.

The mating contact portions 1318A and 1318B may be formed from the same sheet of metal as the conductive elements. However, it should be appreciated that, in some embodiments, conductive elements may be formed by attaching separate mating contact portions to other conductors to form the intermediate portions. For example, in some embodiments, intermediate portions may be cables such that the conductive elements are formed by terminating the cables with mating contact portions.

In the embodiment illustrated, the mating contact portions are tubular. Such a shape may be formed by stamping the conductive element from a sheet of metal and then rolling the mating contact portions into a tubular shape. The circumference of the tube may be large enough to accommodate a pin from a mating pin module, but may conform to the pin. The tube may be split into two or more segments, forming compliant beams. Two such beams are shown in FIG. 12. Bumps or other projections may be formed in distal portions of the beams, creating contact surfaces. Those contact surfaces may be coated with gold or other conductive, ductile material to enhance reliability of an electrical contact.

When conductive elements 1310A and 1310B are mounted in central member 1110, mating contact portions 1318A and 1318B fit within openings 1220A 1220B. The mating contact portions are separated by wall 1230. The distal ends 1320A and 1320B of mating contact portions

1318A and 1318 B may be aligned with openings, such as opening 1222B, in platform 1232. These openings may be positioned to receive pins from the mating pin module 300. Wall 1230, platform 1232 and insulative projecting members 1042A and 1042B may be formed as part of portion 1110, such as in one molding operation. However, any suitable technique may be used to form these members.

FIG. 12 shows a further technique that may be used, instead of or in addition to techniques described above, for reducing energy in undesired modes of propagation within the waveguides formed by the reference conductors in transition regions 1150. Conductive or lossy material may be integrated into each module so as to reduce excitation of undesired modes or to damp undesired modes. FIG. 12, for example, shows lossy region 1215. Lossy region 1215 may be configured to fall along the center line between signal conductors 1310A and 1310B in some or all of region 1150. Because signal conductors 1310A and 1310B jog in different directions through that region to implement the edge to broadside transition, lossy region 1215 may not be bounded by surfaces that are parallel or perpendicular to the walls of the waveguide formed by the reference conductors. Rather, it may be contoured to provide surfaces equidistant from the edges of the signal conductors 1310A and 1310B as they twist through region 1150. Lossy region 1215 may be electrically connected to the reference conductors in some embodiments. However, in other embodiments, the lossy region 1215 may be floating.

Though illustrated as a lossy region 1215, a similarly positioned conductive region may also reduce coupling of energy into undesired waveguide modes that reduce signal integrity. Such a conductive region, with surfaces that twist through region 1150, may be connected to the reference conductors in some embodiments. While not being bound by any particular theory of operation, a conductor, acting as a wall separating the signal conductors and as such twists to follow the twists of the signal conductors in the transition region, may couple ground current to the waveguide in such a way as to reduce undesired modes. For example, the current may be coupled to flow in a differential mode through the walls of the reference conductors parallel to the broadside coupled signal conductors, rather than excite common modes.

FIG. 13 shows in greater detail the positioning of conductive members 1310A and 1310B, forming a pair 1300 of signal conductors. In the embodiment illustrated, conductive members 1310A and 1310B each have edges and broader sides between those edges. Contact tails 1330A and 1330B are aligned in a column 1340. With this alignment, edges of conductive elements 1310A and 1310B face each other at the contact tails 1330A and 1330B. Other modules in the same wafer will similarly have contact tails aligned along column 1340. Contact tails from adjacent wafers will be aligned in parallel columns. The space between the parallel columns creates routing channels on the printed circuit board to which the connector is attached. Mating contact portions 1318A and 1318B are aligned along column 1344. Though the mating contact portions are tubular, the portions of conductive elements 1310A and 1310B to which mating contact portions 1318A and 1318B are attached are edge coupled. Accordingly, mating contact portions 1318A and 1318B may similarly be said to be edge coupled.

In contrast, intermediate portions 1314A and 1314B are aligned with their broader sides facing each other. The intermediate portions are aligned in the direction of row 1342. In the example of FIG. 13, conductive elements for a right angle connector are illustrated, as reflected by the right

angle between column **1340**, representing points of attachment to a daughtercard, and column **1344**, representing locations for mating pins attached to a backplane connector.

In a conventional right angle connector in which edge coupled pairs are used within a wafer, within each pair the conductive element in the outer row at the daughtercard is longer. In FIG. **13**, conductive element **1310B** is attached at the outer row at the daughtercard. However, because the intermediate portions are broadside coupled, intermediate portions **1314A** and **1314B** are parallel throughout the portions of the connector that traverse a right angle, such that neither conductive element is in an outer row. Thus, no skew is introduced as a result of different electrical path lengths.

Moreover, in FIG. **13**, a further technique for avoiding skew is introduced. While the contact tail **1330B** for conductive element **1310B** is in the outer row along column **1340**, the mating contact portion of conductive element **1310B** (mating contact portion **1318 B**) is at the shorter, inner row along column **1344**. Conversely, contact tail **1330A** conductive element **1310A** is at the inner row along column **1340** but mating contact portion **1318A** of conductive element **1310A** is in the outer row along column **1344**. As a result, longer path lengths for signals traveling near contact tails **1330B** relative to **1330A** may be offset by shorter path lengths for signals traveling near mating contact portions **1318B** relative to mating contact portion **1318A**. Thus, the technique illustrated may further reduce skew.

FIGS. **14A** and **14B** illustrate the edge and broadside coupling within the same pair of signal conductors. FIG. **14A** is a side view, looking in the direction of row **1342**. FIG. **14B** is an end view, looking in the direction of column **1344**. FIGS. **14A** and **14B** illustrate the transition between edge coupled mating contact portions and contact tails and broadside coupled intermediate portions.

Additional details of mating contact portions such as **1318A** and **1318B** are also visible. The tubular portion of mating contact portion **1318A** is visible in the view shown in FIG. **14A** and of mating contact portion **1318B** in the view shown in FIG. **14B**. Beams, of which beams **1420** and **1422** of mating contact portion **1318B** are numbered, are also visible.

The inventors have recognized and appreciated that the member **630** in FIG. **6** is suitable for many applications, but when used over large areas is susceptible to small gaps opening between portions of conductive shielding. For example, small gaps may open in different locations between a conductive portion on member **630** and a surface ground pad on a PCB and/or between a conductive portion on member **630** and reference conductors **1010** on the wafer modules **810**. Small gaps can undesirably impact signal integrity and introduce signal crosstalk, particularly when used in a very high-density interconnection system that carries very high-frequency signals. The small gaps can allow energy from the differential mode supported by the differential conductors to leak out of the waveguide formed by the reference conductor and contribute to signal loss. The small gaps may also contribute to unwanted mode conversion at the connector interface with the PCB. A compliant shield that can mitigate signal loss and mode conversion is described in connection with FIG. **15** through FIG. **17B** and FIGS. **22A-B**.

FIG. **15** illustrates an embodiment of a two piece compliant shield **1500** that may be used with a plurality of wafer modules. To simplify the drawings, the compliant shield is shown for use with six differential pairs of conductors, though the invention is not limited to only six. A compliant

shield may be used with, for example, 12, 16, 32, 64, 128 differential pairs of conductors or any other suitable number of differential pairs of conductors.

According to some embodiments, a compliant shield **1500** may include an insulative portion **1504** and a compliant conductive member **1506**. The insulative portion may be formed from a hard or firm polymer, and the compliant conductive member may be formed from a conductive elastomer. The insulative portion **1504** may be configured to receive contact tails from the wafer modules **1310**. The compliant conductive member may be configured to abut the insulative portion, and to provide electrical connectivity between the reference conductors **1010** on the wafer modules **1310** and a reference pad (not shown) on a PCB. In some cases, an insulative portion **1504** may not be used, and the compliant conductive member **1506** may abut the ends of the wafer modules.

The insulative portion **1504** may be a molded or cast component, and may be planar in some embodiments. In some implementations, the insulative portion may include surface structure as depicted in FIG. **15**, and have a first level **1508**, which may be generally planar. In some cases, the first level may have openings **1512** that receive ends of the wafer modules **130**, as depicted in FIG. **16**. The openings **1512** may be sized and shaped to receive tabs **1502** that extend from the wafer modules and connect to reference conductors **1010** of the wafer modules. As shown, tabs **1502** extend above the reference conductor **1010**. Tabs may be electrically connected to surface pads **1910** on printed circuit boards through compliant shield **1500**. In some embodiments, tabs may be adjacent to contact tails of signal conductors also extending from the connector. In the illustrated embodiment, two tabs are aligned parallel to column **1340** at one edge of the contact tail region **820** and two tabs are at the opposing edge of the contact tail region **820**. One or more tabs may be formed and arranged in any suitable way.

The insulative portion may include a plurality of raised islands **1510** extending from the first level by a distance d_1 . The islands may have walls **1516** extending from the first level **1508** and supporting the islands above the first level. There may be channels or notches **1518** formed on the edges of the islands **1510** that are sized and shaped to receive the tabs **1502** from the wafer modules. The island edges at the notches **1518** may provide a backing for the ends of the tabs **1502**, so that lateral force can be applied against the tabs. When the insulative portion is installed over the ends of the wafer modules, the ends of the tabs **1502** may be below or approximately flush with a surface of the islands that is toward a PCB (not shown) to which the connector connects.

The insulative portion **1504** may include contact slots **1514A**, **1514B** and **1515** that are formed in and extend through the islands. The contact slots may be sized and positioned to receive the contact tails **610** and to allow the contact tails to pass therethrough. In some embodiments, a plurality of contact slots may have two closed ends. In some embodiments, a plurality of contact slots may have one closed end and one open end. For example, each island **1510** has four contact slots with one open end that accommodate four contact tails from a wafer module. In some embodiments, contact slots may have an aspect ratio between 1.5:1 and 4:1. The contact slots **1514A**, **1514B** may be arranged in a repeating pattern of subpatterns. For example, each island **1510** may have a copy of the subpattern.

In some embodiments, at least the islands **1510** of the insulative portion **1504** may be formed of a material that has a dielectric constant that establishes a desired impedance for

the signal conductors in the mounting interface of the connector. In some embodiments, the relative dielectric constant may be in the range of 3.0 to 4.5. In some embodiments, the relative dielectric constant may be higher, such as in the range of 3.4 to 4.5. In some embodiments, the relative dielectric constant of the island may be in one of the following ranges: 3.5 to 4.5, 3.6 to 4.5, 3.7 to 4.5, 3.8 to 4.5, 3.9 to 4.5, or 4.0 to 4.5. Such relative dielectric constants may be achieved by selection of a binder material in combination with a filler. Known materials may be selected to provide a relative dielectric constant of up to 4.5, for example. Relative dielectric constants in these ranges may lead to a higher dielectric constant for the islands than for the insulative housing of the connector. The islands may have a relative dielectric constant that is, in some embodiments, at least 0.1, 0.2, 0.3, 0.4, 0.5 or 0.6 higher than the connector housing. In some embodiments the difference in relative dielectric constant will be in the range of 0.1 to 0.3, or 0.2 to 0.5, or 0.3 to 1.0.

The compliant conductive member **1506** may include a plurality of openings **1520** sized and shaped to receive the islands **1510** when mounted to the insulative portion **1504**, as illustrated in FIG. 17A and FIG. 17B. In some embodiments, the openings **1520** are sized and shaped so that interior walls of the compliant conductive member **1506** contact reference tabs **1502** and reference contact tails extending through the islands **1510** when installed over the insulative portion **1504**.

In an uncompressed state, the compliant conductive member **1506** has a thickness **d2**. In some embodiments, the thickness **d2** may be about 20 mil, or in other embodiments between 10 and 30 mils. In some embodiments, **d2** may be greater than **d1**. Because the thickness **d2** of the compliant conductive member is greater than the height **d1** of the islands **1510**, when the connector is pressed onto a PCB engaging the contact tails, the compliant conductive member is compressed by a normal force (a force normal to the plane of the PCB). As used herein, "compression" means that the material is reduced in size in one or more directions in response to application of a force. In some embodiments, the compression may be in the range of 3% to 40%, or any value or subrange within the range, including for example, between 5% and 30% or between 5% and 20% or between 10% and 30%, for example. Compression may result in a change in height of the compliant conductive member in a direction normal to the surface of a printed circuit board (e.g., **d2**). A reduction in size may result from a decrease in volume of the compliant member, such as when the compliant member is made from an open-cell foam material from which air is expelled from the cells when a force is applied to the material. Alternatively or additionally, the change in height in one dimension may result from displacement of the material. In some embodiments, the material forming the compliant conductive member, when pressed in a direction normal to the surface of a printed circuit board, may expand laterally, parallel to the surface of the board.

The compliant conductive member may have different feature sizes at different areas as a result of the positions of the openings **1520**. In some embodiments, the thickness **d2** may not be uniform across the whole member but rather may depend on the feature sizes of the member. For example, area **1524** may have bigger dimensions and/or larger area than area **1522**. As a result, when the connector is pressed onto a PCB, the normal force may cause less compression at area **1524** than area **1522**. In order to achieve similar amount of lateral expansion and thus consistent contact with the

reference tabs and reference contact tails, **d2** around area **1524** may be thicker than **d2** around area **1522**.

The compression of the compliant conductive member can accommodate a non-flat reference pad on the PCB surface and cause lateral forces within the compliant conductive member that laterally expand the compliant conductive member to press against the reference tabs **1502** and reference contact tails. In this manner, gaps between the compliant conductive member and reference tabs and reference contact tails and between the compliant conductive member and reference pad on the PCB can be avoided.

A suitable compliant conductive member **1506** may have a volume resistivity between 0.001 and 0.020 Ohm-cm. Such a material may have a hardness on the Shore A scale in the range of 35 to 90. Such a material may be a conductive elastomer, such as a silicone elastomer filled with conductive particles such as particles of silver, gold, copper, nickel, aluminum, nickel coated graphite, or combinations or alloys thereof. Non-conductive fillers, such as glass fibers, may also be present. Alternatively or additionally, the conductive complaint material may be partially conductive or exhibit resistive loss such that it would be considered a lossy material as described above. Such a result may be achieved by filling all or portions of an elastomer or other binder with different types or different amounts of conductive particles so as to provide a volume resistivity associated with the materials described above as "lossy." In some embodiments, the conductive compliant member may have an adhesive backing such that it may stick to the insulative portion **1504**. In some embodiments a compliant conductive member **1506** may be die cut from a sheet of conductive elastomer having a suitable thickness, electrical, and other mechanical properties. In some implementations, a compliant conductive member may be cast in a mold. In some embodiments, the compliant conductive member **1506** of the compliant shield **1500** may be formed from a conductive elastomer and comprise a single layer of material.

FIG. 16 shows an insulative portion **1504** attached to two wafer modules **1310** of a connector, according to some embodiments. Contact tails **610** from the wafer modules pass through contact slots **1514A** and **1514B** and are electrically isolated from each other by dielectric material of islands **1510** within the insulative portion. Tabs **1502** pass through openings **1512** and abut notches **1518** in walls **1516** on the islands. The tabs are electrically isolated from the differential pair of contact tails by dielectric material of the insulative portion.

FIG. 17A and FIG. 17B show the conductive compliant member **1506** mounted around the islands **1510**, according to some embodiments. Tabs **1502** may electrically connect to surface pads on a printed circuit board through the conductive compliant member, when the connector is pressed onto a PCB. As described above, the compliant conductive member may be compressed in a direction perpendicular to the surface of a PCB when the connector is pressed onto the PCB, and expand laterally towards the island walls **1516**, pressing against the tabs **1502** and reference contact tails. The view in 17B shows a board-facing surface of the compliant shield **1500**, and shows four reference contact tails and differential contact tails extending through contact slots **1514A** and **1514B** for two wafer modules. The regions between islands **1510** are filled with conductive compliant material.

In the embodiment illustrated, each subpattern includes a pair of contact slots **1514A**, **1514B** aligned with longer dimensions disposed in a line and at least two additional contact slots **1515**. The longer dimensions of contact slots

1515 disposed in parallel lines that are perpendicular to the line of the pair of contact slots **1514A**, **1514B**. In some embodiments, the contact tails **610** of each module are arranged in a pattern with the contact tails of the signal conductors in the center and contact tails of the shield at the periphery. In some embodiments, contact slots **1514A**, **1514B** are positioned to receive contact tails **610** that carry signal conductors and contact slots **1515** are positioned to receive contact tails that carry reference conductors.

FIG. **18** illustrates a connector footprint **1800** on a printed circuit board **1802** to which a connector as described herein might be mounted, according to some embodiments. FIG. **18** illustrates a pattern of vias **1805**, **1815** in the printed circuit board to which contact tails of a connector **600**, as described above, may be mounted. The pattern of vias shown in FIG. **18** may correspond to the pattern of contact tails for wafer modules **1310** as illustrated, for example, in FIG. **15**. A module footprint **1820** for one wafer module may include a pattern of vias that is repeated across a surface of a PCB **1802** to form a connector footprint. As was the case for the connector illustrated in FIG. **15**, there may be more than six module footprints for larger connectors.

Module footprint **1820** may include a pair of signal vias **1805A** and **1805B** positioned to receive contact tails from a differential pair of signal conductors. One or more reference or ground vias **1815** may be arranged around the pair of signal vias. For the illustrated embodiment, pairs of reference vias are located at opposing ends of the pair of signal vias. The illustrated pattern arranges the reference vias in columns, aligned with the column direction of the connector, with routing channel regions **1830** between columns. This configuration provides relatively wide routing channel regions within a printed circuit board that are easily accessed by the differential signal pairs, so that a high-density interconnectivity may be achieved with desirable high-frequency performance.

FIG. **19** illustrates a connector footprint **1900** on a printed circuit board **1902** configured for use with a compliant shield **1500**, according to some embodiments. The embodiment of FIG. **19** differs from the embodiment of FIG. **18** in that each module footprint **1920** includes a conductive surface pad **1910**. According to some embodiments, the surface pads **1910** may electrically connect to the reference vias **1815** (e.g., at the vias' peripheries), and thereby connect to one or more internal reference layers (e.g., ground planes) of the printed circuit board. Holes **1912** may be formed in the surface pads, such that vias that receive contact tails from differential signal conductors are electrically isolated from the surface pads. In the embodiment illustrated, holes are in the shape of an oval. However, it is not a requirement that the holes are oval-shaped, and in some embodiments, different shapes may be used, such as rectangular, circular, hexagonal, or any other suitable opening shape. In some implementations, the surface pads **1910** may be formed from a single continuous layer of conductive material (e.g., copper or a copper alloy).

The inventors have recognized and appreciated that in embodiments in which a printed circuit board includes a conductive surface layer, such as surface pads **1910**, that is contacted by a conductive structure connecting ground structures within a connector or other component to grounds within the printed circuit board, shadow vias may be positioned to shape the current flow through the conductive surface layer. Conductive shadow vias may be placed near contact points on the conductive surface layer of members that connect to the ground structure of the connector. This positioning of shadow vias limits the lengths of a primary

conductive path from that contact point to a via that couples that current flow into the inner ground layers of the printed circuit board. Limiting current flow in the ground conductors in a direction parallel to the surface of the board, which is perpendicular to the direction of signal current flow, may improve signal integrity.

FIG. **20** illustrates a connector footprint **2000** on a printed circuit board **2002** configured for use with a compliant shield, according to a further embodiment. The embodiment of FIG. **20** differs from the embodiment of FIG. **19** in that a pair of shadow vias **2010** are incorporated into the module footprint **2020** adjacent to vias for differential signal conductors **1805A**, **1805B**. The shadow vias **2010** may be electrically connected to the surface pads **1910**. The shadow vias may also electrically connect to one or more internal reference layers (e.g., ground planes) of the printed circuit board such that surface pads are also electrically connected to the ground plane through the shadow vias. When a connector is installed, the conductive compliant material **1506** may press against the reference tabs **1502** and the surface pads **1910** above the shadow vias **2010**, and thereby create an essentially direct electrically conductive path from the reference tabs, through the compliant shield, to the surface pads, shadow vias, and to the one or more reference layers of the printed circuit board.

The shadow vias **2010** may be located adjacent to signal vias **1805A**, **1805B**. In the illustrated example, a pair of shadow vias **2010** are located on a first line **2022** that is perpendicular to a second line **2024** that passes through signal vias **1805A**, **1805B** in a direction of the column **1340**. The first line **2022** may be located midway between signal vias **1805A** and **1805B**, such that the pair of shadow vias are equally spaced from signal vias **1805A** and **1805B**. In some embodiments in which more shadow vias are included in each module footprint **2020**, shadow vias may be aligned with signal vias in a direction perpendicular to first line **2022**.

Shadow vias **2022** may at least partially overlap the edges of holes **1912**. In further embodiments, each module footprint **2020** may include more than one pair of shadow vias. Furthermore, the shadow vias may be implemented as one or more circular shadow vias or one or more slot-shaped shadow vias.

According to some embodiments, the shadow vias **2010** may be smaller than vias used to receive contact tails of the connector (e.g., smaller than signal vias **1805A**, **1805B**, and/or reference vias **1815**). In embodiments where the shadow vias do not receive contact tails, they may be filled with conductive material during the manufacture of the printed circuit board. As a result, their unplated diameter may be smaller than the unplated diameter of the vias that receive contact tails. The diameters may be, for example, in the range of 8 to 12 mils, or at least 3 mils less than the unplated diameter of the signal or reference vias.

In some embodiments, the shadow vias may be positioned such that the length of a conducting path through the surface layer to the nearest shadow via coupling the conductive surface layer to an inner ground layer may be less than the thickness of the printed circuit board. In some embodiments, the conducting path through the surface layer may be less than 50%, 40%, 30%, 20% or 10% of the thickness of the board.

In some embodiments, shadow vias may be positioned so as to provide a conducting path through the surface layer that is less than the average length of the conducting paths for signals between the connector, or other component mounted to the board, and inner layers of the board where the signal

vias are connected to the conductive traces. In some embodiments, the shadow vias may be positioned such that the conducting path through the surface layer may be less than 50%, 40%, 30%, 20% or 10% of the average length of the signal paths.

In some embodiments, shadow vias may be positioned so as to provide a conducting path through the surface layer that is less than 5 mm. In some embodiments, the shadow vias may be positioned such that conducting path through the surface layer may be less than 4 mm, 3 mm, 2 mm or 1 mm.

FIG. 21A illustrates a plan view of a connector footprint **2100** on a printed circuit board **2102**, according to some implementations. For the illustrated embodiment, an outline of a compliant conductive member **1506** is shown by dashed lines. In the embodiment illustrated, a conductive surface pad **2110** is patterned to have additional structure around each module footprint **2120**. For example, there may be a plurality of repeated module subpatterns that are linked by bridges **2106**. Between the bridges may be voids **2104** into which the compliant conductive member may deform. The bridges may be arranged to create short conduction paths between the compliant conductive member and reference vias and shadow vias that connect to inner reference or ground planes of the printed circuit board. For example, bridges **2106** may be patterned to conductively link adjacent reference vias and adjacent shadow vias. By having raised bridges in close proximity to the reference and shadow vias and allowing the compliant conductive member to deform into the voids **2104**, the electrical connectivity between the compliant conductive member and the reference and shadow vias can be improved in the immediate vicinity of the vias. In some embodiments, the thickness **d3** of surface pad may be between 1 mil and 4 mils. In some embodiments, the thickness of surface pad may be between 1.5 mils and 3.5 mils.

Each subpattern **2120** may align with a corresponding opening **1520** in the compliant conductive member **1506**. In some embodiments, the reference vias **1815** for a module may be within an opening **1520**, whereas in other embodiments the reference vias may be partly within an opening and partly covered by the compliant conductive member **1506**. In some embodiments, the reference vias **1815** for a module may be fully covered by the compliant conductive member. In some embodiments, shadow vias **1805** for a module may be within an opening **1520**, whereas in other embodiments the shadow vias may be partly within an opening and partly covered by the compliant conductive member. In some embodiments, the shadow vias for a module may be fully covered by the compliant conductive member.

FIG. 21B illustrates a cross-sectional view taken along the outline shown in FIG. 21A. The bridges **2106** and voids **2104** may alternate across a surface of the printed circuit board **2102**. When mounted, a compliant conductive member **1506** can extend into the voids and press against the surface of the bridges in the immediate vicinity of reference tabs **1502** and reference contact tails. In order to make reliable contact, the compliant conductive member may be compressed by an amount sufficient to account for any variations in surface heights of the board and any variations in separation between the connector and the board when the connector is inserted. In some embodiments, the deformation of the compliant conductive member may be in a range of 1 mil to 10 mil. The voids provide a volume into which the compliant conductive member may deform, allowing adequate compression of the compliant conductive member, and thereby providing a more uniform amount of contact

force between the compliant conductive member and the reference tabs and pads on the printed circuit board. It should be appreciated that voids, enabling adequate compression of the compliant compressive member, may be created in any suitable way. In further embodiments, for example, voids may be created by removing portions of connector housing, such as first level **1508** of insulative portion **1504**.

FIG. 22A shows a partial plan view of a board-facing surface of a compliant shield **2200** mounted to a connector and shows four reference contact tails, reference tabs **1502**, and contact tails **1330A**, **1330B** of differential signal conductors. The compliant shield **2200** may comprise only a compliant conductive member **2206** in some embodiments, and may be formed from a conductive elastomer as described above. According to some embodiments, a retaining member **2210** (or plurality of retaining members abutted at the dashed lines **2212**) may be placed over the ends of the wafer modules and inserted in the connector to hold the ends of the wafer modules in an array. The retaining piece **2210** or pieces may be formed from a hard or firm polymer that is insulative. The retaining piece or pieces **2210** may include openings **2204** that are sized and positioned to receive ends of the wafer modules **1000** and may not include islands **1510**. In some embodiments, a retaining piece or pieces may not be used. Instead, the compliant conductive member **2206** may contact members **900** that are used to retain the wafer modules **1000**.

FIG. 22B illustrates a cross-sectional view taken along the outline shown in FIG. 22A. Contact tail **1330A** of a differential signal conductor may be isolated from tabs **1502** by insulative housing **1100**. When mounted, the compliant conductive member **2206** may press against the retaining piece or pieces **2210** (or member **900**) and deform laterally to press against tabs **1502** and/or reference contact tails. In the illustrated example, the insulative housing **1100** extrudes from the retaining piece or pieces such that it may provide a backing for the ends of the tabs. In some embodiments, the retaining piece or pieces may have portions that fill the area illustrated as opening **2204** and have a designed height to provide a backing for the ends of the tabs.

FIG. 23 illustrates further details of a wafer module attached with a compliant shield **1506** by a cross-sectional view of the marked plane **23** in FIG. 17A. An organizer **2304** may be placed over the ends of wafer modules and inserted in the connector to hold the ends of the wafer modules in an array. The organizer may be the insulative portion **1504** or the retaining piece **2210**. The organizer may include openings **2306** that are sized and positioned to receive conductive elements **1310A**, **1310B** that are held in the grooves of insulative housing **1100**. To accommodate tolerances the openings **2306** may be larger than the contact tails of the conductive elements **1310A**, **1310B**, leaving within openings **2306**.

Additionally, in the illustrated embodiment, the contact tails of conductive elements are press fit and have necks **2302** that occupy spaces smaller than the openings **2306**. The inventors have recognized and appreciated that the spaces left in the openings filled with air may cause impedance spike at the mounting interface of the connector to a PCB (not shown). To compensate for the impedance spike, materials with dielectric constant higher than that of the insulative housing **1100** may be used to form the organizer. For example, the insulative housing may be formed of materials with a relative dielectric constant that is less than 3.5. The organizer may be formed of materials with relative dielectric constant above 4.0, such as in the range of 4.5 to

5.5. In some embodiments, the organizer may be formed by adding filler to a polymer binder. The filler, for example, may be titanium dioxide in a sufficient quantity to achieve a relative dielectric constant in the desired range.

FIG. 24 is an isometric view of two wafer modules 2400A and 2400B, according to some embodiments. The differences between wafer modules 2400A-B and wafer modules 810A-D in FIG. 8 include that wafer modules 2400A-B comprise additional tabs 2402A and 2402B extending from the reference conductors 1010A and 1010B respectively.

In some embodiments, the tabs 2402A and 2402B may be resilient and, when the connector is mated with a board, may deform to accommodate manufacturing variations in separation between the board and the connector. The tabs may be made of any suitable compliant, conductive materials, such as superelastic and shape memory materials. Reference conductors 1010 may include projections with various sizes and shapes, such as 2420A, 2420B, and 2420C. These projections impact the separation, in a direction perpendicular to the axis of the signal conductor pair, between portions of the signal conductor pair and the reference conductors 1010A and 1010B. This separation, in combination with other characteristics, such as the width of the signal conductors in those portions, may control the impedance in those portions such that it approximates the nominal impedance of the connector or does not change abruptly in a way that may cause signal reflections.

In some embodiments, a compliant shield may be implemented as a conductive structure positioned between tails of signal conductors in the space between the mating surface of a connector and an upper surface of a printed circuit board. The effectiveness of the shield may be increased when those conductive portions are electrically coupled to compliant portions that ensure reliable connection of the compliant shields to ground structures in the connector and/or the printed circuit board over substantially all of the area of the connector.

FIG. 25A is an isometric view of a compliant shield 2500 that may be used with a plurality of wafer modules, according to some embodiments. To simplify the drawings, the compliant shield is shown for used with an 8x4 array of wafer modules, though the invention is not limited to this array size.

FIG. 25B is an enlarged plan view of the area marked as 25B in FIG. 25A, which may correspond to one of multiple wafer modules in a connector. The compliant shield may include a conductive body portion 2504 with a plurality of compliant fingers 2516. The compliant fingers 2516 may be elongated beams. Each beam may have a proximal end integral with the conductive body portion and a free distal end.

The conductive body portion 2504 may include a plurality of first size openings 2506 for contact tails of a pair of differential signal conductors 1310A-B to pass through and second size openings 2508 for contact tails of reference conductors to pass through. The compliant fingers 2516 may be resilient in a direction that may be substantially parallel to the contact tails of the signal conductors. Alternatively or additionally, the compliant fingers may be resilient in a direction, in which the contact tails of the connector insert into the openings.

In some embodiments, the openings 2506 and 2508 may be arranged in a repeating pattern of subpatterns. Each subpattern may correspond to a respective wafer module. Each subpattern may include at least one opening 2506 for signal conductors to pass through without contacting the conductive body portion such that the signal conductors may

be electrically isolated from the compliant shield. Each subpattern may include at least one opening 2508 for reference conductors to pass through. The opening 2508 may be positioned and sized such that the reference conductors may be electrically connected to the conductive body portion and thus to the compliant shield. In the illustrated example, the openings 2506 are oval-shaped having longer axes 2512 and shorter axes 2514. The openings 2508 are slots having a ratio between a longer dimension 2518 and a shorter dimension 2520 of at least 2:1. The illustrated subpattern in FIG. 25B has four openings 2508, the longer dimensions of which are disposed in parallel lines that are perpendicular to the longer axis of the opening 2506.

In some embodiments, the conductive body portion 2504 may include a plurality of openings 2502. Each opening 2502 may have a compliant finger extending from an edge 2522 of the opening. Such openings may result from a stamping and forming operation in which compliant beams 2516 are cut from a body portion 2504.

Other openings or features may be present in body portion 2504. In some embodiments, openings may be sized and positioned for tabs 2402A and 2402B to pass through such that the conductive body portion may be electrically connected to the reference conductors of a wafer module. Alternatively or additionally, openings 2508 may have at least one dimension that is smaller than the corresponding dimension of the reference conductor inserted into that opening. The body portion 2504 adjacent that opening may be shaped such that it will flex or deform when a reference conductor is inserted into the opening, enabling the reference conductor to be inserted, but providing contact force on reference conductor once inserted such that there is an electrical connection between the reference conductor and the body portion 2504. Such an electrical connection may be 10 Ohms or less, such as between 10 Ohms and 0.01 Ohms. A connection may be, in some embodiments 5 Ohms, 2 Ohms 1 Ohm, or less. In some embodiments, the contact may be between 2 Ohms and 0.1 Ohms, in some embodiments. Such contacts may be formed by cutting from the body portion 2504 adjacent the opening as a cantilevered beam or a torsional beam affixed to the body portion 2504 at two ends. Alternatively, the body portion may be shaped with an opening bounded by a segment that is placed into compression when a reference conductor is inserted.

The compliant shield 2500 may be made of a material with desired conductivity for the current paths. Suitable conductive materials to make at least a portion of the conductive body portion include metals, metal alloys, superelastic and shape memory materials. In some embodiments, the compliant shield may be made of a first material coated with a second material, the conductivity of which is greater than that of the first material.

In some embodiments, the compliant shield may be manufactured by stamping openings in a piece of metal, which may be substantially planar. Compliant fingers 2516, for example, may be manufactured by cutting elongated beams from the piece of metal with a proximal end attached to the piece of metal. In an embodiment in which the body portion is generally planar, the free distal end will be bent out of the plane of the body portion. Conductive, compliant metals that may be shaped in this way using conventional stamping and forming techniques are known in the art and are suitable for manufacturing a compliant shield.

The beams may be bent out of the plane of the conductive body portion 2504 by an amount exceeding the tolerance in positioning a mounting face of a connector against a surface of a printed circuit board. With beams of this shape, the free

distal end of the beam will contact the surface of the printed circuit board whenever the connector is mounted to the printed circuit board, so long whenever the connector is positioned within the tolerance. Moreover, the beam will be at least partially compressed, ensuring that the beam generates contact force that ensures reliable electrical connection. In some embodiments, the contact force will be in the range of 1 to 80 Newtons, or, in some embodiments, between 5 and 50 Newtons, or between 10 and 40 Newtons, such as between 20 and 40 Newtons.

FIG. 26A is a cross-sectional view corresponding to the cutline 26 in FIG. 25B, showing the compliant shield mounted to a connector (e.g., connector 600), according to some embodiments. In an uncompressed state, the conductive body portion 2504 of the compliant shield 2500 may be away from surface 2606 of a printed circuit board by a distance d1. In the illustrated example, each of the reference tails 1010A and 1010B extend through a respective opening 2508 and makes contact with the conductive body portion. Each of the compliant fingers 2516A and 2516B has a proximal end 2608 integral with the conductive body portion and a free distal end 2610 pressing against the surface of a printed circuit board to which the connector is to be mounted.

When the connector is pressed onto a surface 2606 of a PCB engaging the contact tails, the compliant shield is compressed by a normal force (a force substantially normal to the surface of the PCB). FIG. 26B is a sectional view of the portion of the compliant shield in FIG. 26A in a compressed state. The PCB may have ground pads on the surface. The ground pads may be connected to a ground plane of the PCB through vias. The conductive body portion 2504 may press against the ground pads. The compliant fingers 2516A and 2516B may deform as a result of the normal force. The compliant shield may be away from the surface of the printed circuit board by a distance d2 adjacent to compliant finger 2516A and a distance d3 adjacent to compliant finger 2516B. It should be appreciated that, depending on the variations of gaps between the connector and PCB, d2 and d3 may be the same or different within a module; even if d2 and d3 are the same within one module, they may be different across modules. However, as a result of compliance provided by the fingers 2516A and 2516B, both may make contact with a conducting pad on the printed circuit board.

FIG. 26B illustrates a further embodiment. In the embodiment of FIG. 26B, the compliant shield has, in addition to a body portion 2504, which may be formed of metal, a layer 2604 of lossy material. The lossy material may be on the order of 0.1 to 2 mm thick, or may have any other suitable dimension, such as between 0.1 and 1 mm of thickness.

FIG. 27 illustrates a connector footprint 2700 on a printed circuit board 2702 configured for use with a compliant shield, according to a further embodiment. The embodiment of FIG. 27 differs from the embodiment of FIG. 19 in that shadow vias 2710 are incorporated into the module footprint 2720 adjacent to vias for differential signal conductors 1805A, 1805B. The shadow vias 2710 may be electrically connected to the surface pads 1910. The shadow vias may also electrically connect to one or more internal reference layers (e.g., ground planes) of the printed circuit board such that surface pads are also electrically connected to the ground plane through the shadow vias. When a connector is installed, the conductive body portion 2504 may press against the surface pads 1910 above the shadow vias 2710, and thereby create an essentially direct electrically conductive path from the reference tabs, through the compliant

shield, to the surface pads, shadow vias, and to the one or more reference layers of the printed circuit board.

The shadow vias 2710 may be located adjacent to signal vias 1805A, 1805B. In the illustrated example, a pair of shadow vias 2710 are located on a first line 2722 that is perpendicular to a second line 2724 that passes through signal vias 1805A, 1805B in a direction of the column 1340. The second line 2724 may be located midway between the pair of shadow vias, such that the pair of shadow vias are equally spaced from signal vias 1805A and 1805B. In the illustrated embodiment shadow vias in each module footprint 2720 are aligned with signal vias in a direction perpendicular to first line 2722. However, it is not a requirement that the shadow vias align with signal vias. For example, in some embodiments, a module footprint 2720 may have one shadow via on each side of line 2724, aligned with a line parallel to line 2722, but that passes between the signal vias, and, in some embodiments may be equidistant from the signal vias that form a differential pair. In some embodiments, for each module footprint 2720, at least one shadow via is positioned between the ground vias 1815, for example, positioned between the pairs of reference vias that are located at opposing ends of the pair of signal vias.

Shadow vias 2722 may at least partially overlap the edges of holes 1912. In further embodiments, each module footprint 2720 may include more than one pair of shadow vias. Furthermore, the shadow vias may be implemented as one or more circular shadow vias or one or more slot-shaped shadow vias.

According to some embodiments, the shadow vias 2710 may be smaller than vias used to receive contact tails of the connector (e.g., smaller than signal vias 1805A, 1805B, and/or reference vias 1815). In embodiments where the shadow vias do not receive contact tails, they may be filled with conductive material during the manufacture of the printed circuit board. As a result, their unplated diameter may be smaller than the unplated diameter of the vias that receive contact tails. The diameters may be, for example, in the range of 8 to 12 mils, or at least 3 mils less than the unplated diameter of the signal or reference vias.

In some embodiments, the shadow vias may be positioned such that the length of a conducting path through the surface layer to the nearest shadow via coupling the conductive surface layer to an inner ground layer may be less than the thickness of the printed circuit board. In some embodiments, the conducting path through the surface layer may be less than 50%, 40%, 30%, 20% or 10% of the thickness of the board. Short conducting paths may be achieved by positioning the shadow vias at or near the point of contact, such as between the conductive body portion 2504 and the conductive surface pad 1910.

In some embodiments, shadow vias may be positioned so as to provide a conducting path through the surface layer that is less than the average length of the conducting paths for signals between the connector, or other component mounted to the board, and inner layers of the board where the signal vias are connected to the conductive traces. In some embodiments, the shadow vias may be positioned such that the conducting path through the surface layer may be less than 50%, 40%, 30%, 20% or 10% of the average length of the signal paths.

In some embodiments, shadow vias may be positioned so as to provide a conducting path through the surface layer that is less than 5 mm. In some embodiments, the shadow vias may be positioned such that conducting path through the surface layer may be less than 4 mm, 3 mm, 2 mm or 1 mm.

The frequency range of interest may depend on the operating parameters of the system in which such a connector is used, but may generally have an upper limit between about 15 GHz and 50 GHz, such as 25 GHz, 30 or 40 GHz, although higher frequencies or lower frequencies may be of interest in some applications. Some connector designs may have frequency ranges of interest that span only a portion of this range, such as 1 to 10 GHz or 3 to 15 GHz or 5 to 35 GHz. The impact of unbalanced signal pairs, and any discontinuities in the shielding at the mounting interface may be more significant at these higher frequencies.

The operating frequency range for an interconnection system may be determined based on the range of frequencies that can pass through the interconnection with acceptable signal integrity. Signal integrity may be measured in terms of a number of criteria that depend on the application for which an interconnection system is designed. Some of these criteria may relate to the propagation of the signal along a single-ended signal path, a differential signal path, a hollow waveguide, or any other type of signal path. Two examples of such criteria are the attenuation of a signal along a signal path or the reflection of a signal from a signal path.

Other criteria may relate to interaction of multiple distinct signal paths. Such criteria may include, for example, near end cross talk, defined as the portion of a signal injected on one signal path at one end of the interconnection system that is measurable at any other signal path on the same end of the interconnection system. Another such criterion may be far end cross talk, defined as the portion of a signal injected on one signal path at one end of the interconnection system that is measurable at any other signal path on the other end of the interconnection system.

As specific examples, it could be required that signal path attenuation be no more than 3 dB power loss, reflected power ratio be no greater than -20 dB, and individual signal path to signal path crosstalk contributions be no greater than -50 dB. Because these characteristics are frequency dependent, the operating range of an interconnection system is defined as the range of frequencies over which the specified criteria are met.

Designs of an electrical connector are described herein that improve signal integrity for high frequency signals, such as at frequencies in the GHz range, including up to about 25 GHz or up to about 40 GHz, up to about 50 GHz or up to about 60 GHz or up to about 75 GHz or higher, while maintaining high density, such as with a spacing between adjacent mating contacts on the order of 3 mm or less, including center-to-center spacing between adjacent contacts in a column of between 1 mm and 2.5 mm or between 2 mm and 2.5 mm, for example. Spacing between columns of mating contact portions may be similar, although there is no requirement that the spacing between all mating contacts in a connector be the same.

A compliant shield may be used with a connector of any suitable configuration. In some embodiments, a connector with a broadside-coupled configuration may be adopted to reduce skew. The broadside-coupled configuration may be used for at least the intermediate portions of signal conductors that are not straight, such as the intermediate portions that follow a path making a 90 degree angle in a right angle connector.

While a broadside-coupled configuration may be desirable for the intermediate portions of the conductive elements, a completely or predominantly edge-coupled configuration may be adopted at a mating interface with another connector or at an attachment interface with a printed circuit board. Such a configuration, for example, may facilitate

routing within a printed circuit board of signal traces that connect to vias receiving contact tails from the connector.

Accordingly, the conductive elements inside the connector may have transition regions at either or both ends. In a transition region, a conductive element may jog out of the plane parallel to the wide dimension of the conductive element. In some embodiments, each transition region may have a jog toward the transition region of the other conductive element. In some embodiments, the conductive elements will each jog toward the plane of the other conductive element such that the ends of the transition regions align in a same plane that is parallel to, but between the planes of the individual conductive elements. To avoid contact of the transition regions, the conductive elements may also jog away from each other in the transition regions. As a result, the conductive elements in the transition regions may be aligned edge to edge in a plane that is parallel to, but offset from the planes of the individual conductive elements. Such a configuration may provide a balanced pair over a frequency range of interest, while providing routing channels within a printed circuit board that support a high density connector or while providing mating contacts on a pitch that facilitates manufacture of the mating contact portions.

Although details of specific configurations of conductive elements, housings, and shield members are described above, it should be appreciated that such details are provided solely for purposes of illustration, as the concepts disclosed herein are capable of other manners of implementation. In that respect, various connector designs described herein may be used in any suitable combination, as aspects of the present disclosure are not limited to the particular combinations shown in the drawings.

Having thus described several embodiments, it is to be appreciated various alterations, modifications, and improvements may readily occur to those skilled in the art. Such alterations, modifications, and improvements are intended to be within the spirit and scope of the invention. Accordingly, the foregoing description and drawings are by way of example only.

Various changes may be made to the illustrative structures shown and described herein. For example, a compliant shield was described in connection with a connector attached to a printed circuit board. A compliant shield may be used in connection with any suitable component mounted to any suitable substrate. As a specific example of a possible variation, a compliant shield may be used with a component socket.

Manufacturing techniques may also be varied. For example, embodiments are described in which the daughtercard connector 600 is formed by organizing a plurality of wafers onto a stiffener. It may be possible that an equivalent structure may be formed by inserting a plurality of shield pieces and signal receptacles into a molded housing.

As another example, connectors are described that are formed of modules, each of which contains one pair of signal conductors. It is not necessary that each module contain exactly one pair or that the number of signal pairs be the same in all modules in a connector. For example, a 2-pair or 3-pair module may be formed. Moreover, in some embodiments, a core module may be formed that has two, three, four, five, six, or some greater number of rows in a single-ended or differential pair configuration. Each connector, or each wafer in embodiments in which the connector is waferized, may include such a core module. To make a connector with more rows than are included in the base

module, additional modules (e.g., each with a smaller number of pairs such as a single pair per module) may be coupled to the core module.

Furthermore, although many inventive aspects are shown and described with reference to a daughterboard connector having a right angle configuration, it should be appreciated that aspects of the present disclosure is not limited in this regard, as any of the inventive concepts, whether alone or in combination with one or more other inventive concepts, may be used in other types of electrical connectors, such as backplane connectors, cable connectors, stacking connectors, mezzanine connectors, I/O connectors, chip sockets, etc.

In some embodiments, contact tails were illustrated as press fit “eye of the needle” compliant sections that are designed to fit within vias of printed circuit boards. However, other configurations may also be used, such as surface mount elements, spring contacts, solderable pins, etc., as aspects of the present disclosure are not limited to the use of any particular mechanism for attaching connectors to printed circuit boards.

The present disclosure is not limited to the details of construction or the arrangements of components set forth in the foregoing description and/or the drawings. Various embodiments are provided solely for purposes of illustration, and the concepts described herein are capable of being practiced or carried out in other ways. Also, the phraseology and terminology used herein are for the purpose of description and should not be regarded as limiting. The use of “including,” “comprising,” “having,” “containing,” or “involving,” and variations thereof herein, is meant to encompass the items listed thereafter (or equivalents thereof) and/or as additional items.

What is claimed is:

1. An electrical connector comprising a mounting interface configured for a plurality of signal contact elements and a plurality of reference conductors extended from within the connector to connect to a printed circuit board, the mounting interface comprising:

an insulative portion comprising:

a plurality of first openings, wherein signal contact elements of the plurality of signal contact elements from the electrical connector pass through through respective openings of the plurality of first openings, and

a plurality of second openings, wherein reference conductors of the plurality of reference conductors from the electrical connector pass through respective openings of the plurality of second openings;

contact tails of the reference conductors for mounting to a printed circuit board and contact structures of the reference conductors separate from the contact tails, wherein

the plurality of first openings and the plurality of second openings are arranged in a repeating pattern of subpatterns,

each subpattern comprises a pair of first openings and one or more second openings surrounding the pair of first openings,

the one or more second openings surrounding the pair of first openings comprise openings for the contact structures separate from the contact tails, and

for each subpattern, the one or more second openings surrounding the pair of first openings comprises a pair of slots aligned with longer dimensions disposed in a first line.

2. The electrical connector of claim 1, wherein each of the plurality of first and second openings is a slot having a ratio between a longer dimension and a shorter dimension of at least 2:1.

3. The electrical connector of claim 2, wherein for each subpattern, the pair of first openings are a pair of slots aligned with longer dimensions disposed in a second line.

4. The electrical connector of claim 3, wherein for each subpattern, the second line is perpendicular to the first line.

5. The electrical connector of claim 1, wherein the insulative portion comprises one or more thicker subportions, and

the plurality of first openings extend through the one or more thicker subportions.

6. The electrical connector of claim 1, wherein for each subpattern, the one or more second openings surrounding the pair of first openings comprise at least one opening for at least one contact tail of the reference conductors, and the openings of the one or more second openings for the contact structures are for reference tabs of the reference conductors.

7. The electrical connector of claim 6, wherein for each subpattern, the at least one opening for at least one contact tail of the reference conductors and the openings for reference tabs of the reference conductors extend in directions perpendicular to each other.

8. A component for a mounting interface of an electrical connector configured for a plurality of signal contact elements and a plurality of reference conductors within the connector to pass through the component to connect to a printed circuit board, the component comprising:

an insulative portion comprising:

a plurality of first openings sized and positioned for the plurality of signal contact elements from the electrical connector to pass therethrough;

a plurality of second openings sized and positioned for the plurality of reference conductors from the electrical connector to pass therethrough; and

a conductive portion attached to the insulative portion and configured to provide current flow paths between shields internal to the electrical connector and ground structures of the printed circuit board, wherein

the plurality of first openings and the plurality of second openings are arranged in a repeating pattern of subpatterns, and

each subpattern comprises a pair of first openings and one or more second openings surrounding the pair of first openings.

9. The electrical connector of claim 1, wherein the contact tails have a first shape configured for press fit attachment to the printed circuit board and the contact structures of the reference conductors separate from the contact tails have a second shape that is configured for an electrical connection to the printed circuit board without use of a press fit attachment.

10. An electrical connector, comprising:

a plurality of internal shields;

a board mounting face comprising a plurality of signal contact elements and a plurality of reference conductors wherein at least a portion of the plurality of reference conductors extend from the plurality of internal shields and extend through the board mounting face; and

41

a component for the board mounting face, the component comprising
 an insulative portion comprising
 a plurality of first openings sized and positioned for the plurality of signal contact elements to pass there-through; and
 a plurality of second openings therethrough, wherein the second openings are sized and positioned to receive the plurality of reference conductors, wherein
 the plurality of signal contact elements and the plurality of reference conductors are arranged in a repeating pattern of subpatterns,
 each subpattern comprises a pair of signal contact elements and one or more reference conductors are disposed to surround the pair of signal contact elements,
 the plurality of reference conductors comprise contact tails for mounting to a printed circuit board and contact structures separate from the contact tails, and for each subpattern, each reference conductor comprises broadsides connected by edges, and at least two reference conductors are edge coupled with broadsides aligned in a first line.

11. The electrical connector of claim **10**, wherein for each subpattern,
 each signal contact element comprises broadsides connected by edges, and
 the pair of signal contact elements are edge coupled with broadsides aligned in a second line.

12. The electrical connector of claim **11**, wherein for each subpattern,
 the second line is perpendicular to the first line.

13. The electrical connector of claim **12**, wherein for each subpattern,
 at least two reference conductors are edge coupled with broadsides aligned in a line parallel to the second line.

14. The electrical connector of claim **13**, wherein for each subpattern,
 a broadside of each signal contact element is coupled to a broadside of a reference conductor and aligned with the reference conductor in a line parallel to the first line.

15. The electrical connector of claim **10**, wherein the component comprises
 a conductive portion attached to the insulative portion and configured to provide current flow paths between the plurality of internal shields and ground structures of the printed circuit board.

42

16. The electrical connector of claim **10**, wherein the insulative portion of the component comprises one or more thicker subportions, and
 the plurality of signal contact elements pass through the one or more thicker subportions of the insulative portion of the component.

17. The electrical connector of claim **16**, wherein the one or more thicker subportions are formed of a material that has a dielectric constant higher than that of a housing of the electrical connector such that a desired impedance is established for the signal contact elements.

18. An electronic system comprising the electrical connector of claim **1** in combination with the printed circuit board, wherein the printed circuit board comprises at least one ground pad on a surface and the electrical connector is mounted to the surface, with the mounting interface adjacent the surface such that the contact structures of the reference conductors separate from the contact tails are electrically connected to the at least one ground pad.

19. An electronic system comprising the electrical connector of claim **10** in combination with a printed circuit board for mounting connectors, the printed circuit board comprising:

a plurality of routing layers; and
 a connector footprint comprising:

a plurality of via subpatterns disposed in rows and columns, each via subpattern comprising a pair of signal vias aligned in a line and at least four ground vias being disposed to surround the pair of signal vias, and

a plurality of routing channel regions between columns of via subpatterns, wherein the plurality of routing channel regions each is accessed by more than one signal pairs.

20. The electronic system of claim **19**, wherein the plurality of via subpatterns each comprises one or more shadow vias.

21. The electronic system of claim **20**, wherein for each via subpattern,
 the one or more shadow vias comprise two shadow vias aligned in a direction parallel to the rows.

22. The electronic system of claim **20**, wherein for each via subpattern,
 the one or more shadow vias comprise two shadow vias aligned in a direction parallel to the columns.
