(57) **ABSTRACT**

A mobile medical imaging device that allows for multiple
support structures, such as a tabletop or a seat, to be
attached, and in which the imaging gantry is indexed to the
patient by translating up and down the patient axis. In one
embodiment, the imaging gantry can translate, rotate and/or
tilt with respect to a support base, enabling imaging in
multiple orientations, and can also rotate in-line with the
support base to facilitate easy transport and/or storage of the
device. The imaging device can be used in, for example,
x-ray computed tomography (CT) and/or magnetic reso-
nance imaging (MRI) applications.

CROSS-REFERENCE TO RELATED APPLICATIONS

This Application is a Continuation of application Ser. No. 16/809,010 filed on Mar. 4, 2020. Application Ser. No. 16/809,010 is a continuation of application Ser. No. 15/645,032 filed on Jul. 10, 2017. Application Ser. No. 15/645,032 is a Continuation of application Ser. No. 15/227,119 filed on Aug. 3, 2016. Application Ser. No. 15/227,119 is a Continuation of application Ser. No. 13/359,624 filed on Jan. 27, 2012. Application Ser. No. 13/359,624 is a Continuation of application Ser. No. 12/576,681 filed on Oct. 9, 2009. Application Ser. No. 12/576,681 claims the benefit of U.S. Provisional Application 61/142,494 filed on Jan. 5, 2009.

BACKGROUND OF THE INVENTION

The present invention is in the technical field of medical imaging, including, for example, mobile computed tomography and magnetic resonance imaging devices.

Conventional computed tomography (CT) and magnetic resonance (MR) imaging devices, are typically either immovable or exceedingly difficult to transport and consist of multiple components including the imaging gantry and a separate imaging table. It is difficult to move these devices throughout a hospital because they have not been designed to fit through standard hallways and the imaging table top is unusable or unfit for procedures other than standard diagnostic imaging or do not allow imaging with the patient in a sitting position. In addition, a separate single procedure specific table top is generally indexed to translate into and out of the imaging device throughout a procedure thus limiting its practical applications beyond diagnostic imaging. Moving such devices typically requires several strong persons, or a sturdy wheeled vehicle such as a reinforced wagon or hand cart. The difficulties of moving such a device throughout a hospital or office are multiplied when the device needs to be moved from one floor to another. Further, it is not an uncommon experience to realize that the device cannot pass through the doorway without its widening. Further, the devices cannot readily be moved from spot to spot once inside a room.

BRIEF SUMMARY OF THE INVENTION

In accordance with the present invention, an easily transportable mobile medical imaging device is disclosed. The mobile medical imaging device allows for multiple procedural support structures, such as a surgical table or a seat, to be attached. An imaging gantry is provided that is indexed to the patient by translating up and down the patient axis. In a preferred embodiment, the imaging gantry can translate, rotate and/or tilt with respect to a support base, enabling imaging in multiple orientations, and can also rotate in-line with the support base to facilitate easy transport and/or storage of the device. The imaging device can be used in, for example, x-ray computed tomography and/or magnetic resonance imaging (MRI) (magnetic resonance) applications.

According to one embodiment, a medical imaging system comprises a base; a pedestal mounted to the base; a gimbal support mounted to the base; and a gantry ring that is attached to the gimbal support and is suspended above the top surface of the base. The gantry ring includes an image collection apparatus, such as an x-ray source and an x-ray

detector array, for obtaining image data from an object located within the bore of the gantry ring. The gantry ring can translate in a first direction relative to the base and rotate at least about 90 degrees with respect to an axis extending generally normal to the top surface of the base. In certain embodiments, the gantry ring can also tilt with respect to the gimbal support.

The gimbal support can be a generally U-shaped support having arms extending upwards from the base and connecting to opposite sides of the gantry ring. The gimbal support can translate and rotate with respect to the base in order to translate and rotate the gantry ring on the base. The base is preferably a mobile base having one or more wheels attached to the base.

The imaging system can further comprise a tabletop support mounted to and disposed above the pedestal, the tabletop support extending at least partially into the bore of the gantry ring. The tabletop support can support an object, typically an individual or an animal to be imaged. The tabletop support can be detachable from the pedestal, and the pedestal can be adapted to support any one of a plurality of interchangeable tabletop supports, including, for example, surgical or trauma tables, modular tabletops, and chairs for imaging of a seated patient. The system can include means for adjusting the height of the tabletop support relative to the base, as well as for translating the tabletop support in one or more directions relative to the pedestal.

The gantry ring can have a relatively large imaging bore having a diameter greater than about 38 inches and generally between about 40 and 50 inches. The overall dimensions of the gantry ring are generally relatively small in order to improve the portability of the system. For example, the outer diameter of the gantry is generally less than about 70 inches and the width of the gantry ring is typically about 17 inches or less.

In certain embodiments, the gantry ring rotates with respect to the base between an imaging position, in which the bore of the gantry ring is faced generally in the direction of the pedestal, and a transport position, in which the bore is faced generally perpendicular to the pedestal and in-line with the base. By rotating the gantry ring into the transport position, the overall width of the system is reduced, which allows for easier transport of the system through doors and hallways.

The present invention further includes methods of imaging an object using an imaging system as described above.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

Other features and advantages of the present invention will be apparent from the following detailed description of the invention, taken in conjunction with the accompanying drawings of which:

FIG. 1 is a side view of a mobile imaging system of the invention;

FIG. 2 is a front view of the imaging system of FIG. 1;

FIG. 3 illustrates an imaging system including a tabletop support supporting a patient and the gantry ring tilted and partially rotated relative to the base;

FIG. 4 is a side view of an imaging system with the gantry ring and gimbal support translated to the distal end of the base;

FIG. 5 is a side view of the imaging system of FIG. 4 with the gantry ring and gimbal support translated to the pedestal side of the base;

3

FIG. 6 is a side view of an imaging system with the tabletop support vertically displaced from the pedestal and the gantry ring tilted in a first direction with respect to the gimbal support;

FIG. 7 is a side view of the imaging system of FIG. 6 with the gantry ring tilted in the opposite direction with respect to the gimbal support;

FIG. 8 is a front cross-sectional view of a gantry ring having an x-ray source and an x-ray detector array on a rotor;

FIG. 9 is a side view of the gantry ring;

FIGS. 10A and 10B are side and top views, respectively, of an imaging system of the invention in an imaging position;

FIGS. 11A and 11B are side and top views, respectively, of the imaging system of FIGS. 10A and 10B in a transport position;

FIG. 12 is a side view of an imaging system with a flat operating tabletop support mounted on the pedestal;

FIG. 13 is a side view of an imaging system with a modular, sectional tabletop support mounted on the pedestal;

FIG. 14 is a side view of an imaging system with a tabletop support in the form of a chair for imaging a seated patient;

FIGS. 15A-15C illustrate a patient tabletop support that is transported to an imaging system on a mobile cart for imaging a patient and then removed from the imaging system using the mobile cart;

FIG. 16 is a side view of an imaging system having a rod to reinforce the cantilevered end of the tabletop support;

FIG. 17 is a front perspective view of an imaging system having a chair support mounted to the distal end of the base;

FIG. 18 illustrates an imaging system of the invention performing a helical scanning procedure; and

FIG. 19 illustrates an imaging system of the invention and a specialized support with a medical device for performing a procedure on a patient.

DETAILED DESCRIPTION OF THE INVENTION

Referring to FIGS. 1-7, a mobile imaging system 100 according to one embodiment of the invention includes a mobile base 20, a gimbal support 30, a gantry ring 40, and a pedestal 50. FIGS. 1 and 2 are side and front views, respectively, of the mobile medical imaging system 100. The system 100 includes image collection devices, such as a rotatable x-ray source and detector array or stationary magnetic resonance imaging components, that are housed within the gantry ring 40. The system 100 is configured to collect imaging data, such as, for example x-ray computed tomography (CT) or magnetic resonance imaging (MRI) data, from an object located within the bore 41 of the gantry ring 40, in any manner known in the medical imaging field. As shown in FIG. 3, the pedestal 50 is adapted to support a tabletop support 60 that can be attached to the pedestal 50 in a cantilevered manner and extend out into the bore 41 of the gantry ring 40 to support a patient or other object being imaged.

The base 20 is a sturdy, generally rectilinear support platform. The base 20 may be mobile, with wheels 23 (FIGS. 1 and 2) that allow the entire imaging system 100 to be easily moved. The dimensions of the base 20 are such that the system 100 can be located in and operated comfortably in an operating room or an emergency room or an examination room. The length and width of the base 20 are preferably designed to allow the system 100 to fit through most

4

standard-sized doorways (i.e., generally 24-36 inches wide), and to be easily transported through corridors and elevators generally found in hospitals and other health-care environments.

The gimbal support 30 (FIGS. 1-7) is a generally U-shaped support that is mounted to the top surface of base 20 and includes a pair of arms 31, 33 extending up from base. The arms 31, 33 are connected to opposite sides of gantry ring 40 so that the ring is suspended above base 20 and gimbal support 30.

The gimbal support 30, and the gantry ring 40 to which it is attached, can translate on the base 20, as illustrated in FIGS. 4 and 5. The gimbal support 30 can translate along a substantial portion of the length of the base 20. In certain embodiments, the gimbal support 30 and gantry ring 40 can translate about 2 meters or more, which allows the gantry ring to image along any desired anatomical region of a human patient lying on a patient support. The translation distance is generally at least about 1 meter, which enables full body coverage depending on the orientation of the patient. In one embodiment, the gimbal support 30 can translate over a substantial portion of the base so that the gimbal support 30 and gantry ring 40 can be moved completely out of the way (i.e., in a "park" position) when the gantry is not in use in order to maximize access to the patient, such as for a surgical procedure.

The gantry ring 40 can be connected to the gimbal support 30 such that the ring 40 can pivot about an axis (x-axis in FIG. 2) relative to the gimbal support 30 and the base 20. FIG. 3 illustrates the gantry ring 40 pivoted or tilted with respect to the gimbal support 30. FIGS. 6 and 7 illustrate the gantry ring 40 being tilted in two opposing directions.

The gimbal support 30 is mounted to the base 20 such that the gimbal support 30 and the gantry ring 40 can rotate about an axis (y-axis in FIGS. 1-3) relative to the base 20. This is illustrated in FIG. 3, in which the gimbal support 30 and gantry ring 40 are rotated slightly with respect to the base 20.

The pedestal 50 is mounted to the base 20. As shown in FIGS. 1-7, the pedestal 50 is mounted to the top surface of the base 20, though it could be mounted elsewhere, such as to the end of the base. The pedestal 50 can be located at or near one end of the base 20, which allows the gimbal support 30 a maximum distance over which to translate on the base.

The pedestal 50 comprises a sturdy support structure that extends generally vertically upwards from the base 20. As shown in FIGS. 3-7, the pedestal 50 is designed to securely hold a tabletop support 60 upon which the object to be imaged is supported. In one embodiment, the pedestal 50 includes a releasable locking mechanism that allows a tabletop support, or a portion thereof, to be attached to the pedestal 50 for imaging operations and removed from the pedestal 50 for storage and transport of the system 100. In addition, as discussed in greater detail below, a plurality of different tabletop supports can be attached and detached from the pedestal, where the tabletop supports are each customized for a particular application.

Generally, the pedestal 50 extends up from the base 20 to a height such that a tabletop support attached to the pedestal 50 will be approximately equal in height to the isocenter of the gantry ring. In certain embodiments, the height of the pedestal 50 can be adjusted up or down in the vertical, y-axis direction. This y-axis movement of the pedestal can be achieved by telescoping the pedestal, or by any other means known in the art, such as with a pole or ball screw. FIGS. 6 and 7, for example, illustrate the pedestal 50 and a tabletop support 60 displaced vertically by distance, d, in the y-axis. Also, in some embodiments, the pedestal 50 is configured so

5

that a tabletop support **60** attached to the top of the pedestal **50** can move relative to the pedestal **50** and base **20**. In some embodiments, the tabletop support **60** can have at least two-degrees-of-freedom relative to the pedestal **50** and base **20**. The tabletop support **60** can translate along the imaging axis (z-axis) to move the tabletop support **60** towards or away from the gantry ring **40**, and preferably into and out of the bore of the gantry ring **40**. FIG. 3 illustrate the tabletop support **60** partially translated by distance, *t*, along the z-axis. In some embodiments, the tabletop support **60** can also translate along the x-axis, or into/out of the page in FIG. 3. The translation of the tabletop support **60** relative to the pedestal and base can be achieved through any known means, such as a rail and bearing system.

According to yet another aspect, the pedestal **50** can rotate with respect to the base **20** about the y-axis.

The imaging system **100** can include one or more mechanical actuators, as are known in the art, to control and effect the above-described motions—i.e., the tilt motion of the gantry ring relative to the gimbal support, the translation and rotation of the gimbal support relative to the base, the up-down motion of the pedestal, the z-axis and x-axis translation of the tabletop support, and the y-axis rotation of the pedestal. All of these respective motions can be controlled by a central computerized system controller **102** (FIG. 3). The system controller **102** can be included on the system, such as housed inside the pedestal **50**, as shown in FIG. 3. In other embodiments, the system controller is located off the system **100**, such as in a mobile cart, and may comprise a general purpose computer programmed to provide the desired control functions and user interface, and is in electrical communication with the system **100**, such as via a cable or wireless link. The control system **102** can also control the operation of the imaging device(s) on the gantry ring **40**, as discussed further below.

It will be understood that the above-described movements of the gantry ring **40**, gimbal support **30**, pedestal **50** and tabletop support **60** are not required in all embodiments, and that some or all of these movements, if provided, can be made manually by an operator rather than by a motorized system. The advantages of the various movements described above is that they can aid in the loading and unloading of objects to be imaged onto and off of the imaging system, they allow for fine-tuning of the positioning of the object for imaging applications, and they enable a wide variety of imaging angles and scanning operations.

Other components of the system **100** include a power supply **101**, which can be a rechargeable battery-based power supply, a user display **103** and a user input system **105** for controlling the operation of the system. In the embodiment of FIG. 3, these components are shown on the imaging system **100**, for example, housed within or attached to the pedestal **50**, though it will be understood that some or all of these components could be located off the system **100**, such as on a separate mobile cart.

The imaging system **100** can also include a motor that is geared into the wheels **23** to propel the system **100** across a floor. The system **100** can also include a steering mechanism, such as handle **107**. The handle **107** in this embodiment is shown attached to pedestal **50**, though it could be located elsewhere on the system, including on the gimbal support **30**.

Turning now to FIG. 8, the gantry ring **40** is shown in a head-on, cross-sectional view to illustrate the imaging components inside the gantry ring **40**, according to one embodiment of the invention. As shown in FIG. 8, the gantry ring **40** comprises a generally O-shaped housing that surrounds

6

and defines an inner bore **41**. Inside the housing are imaging components, including in this embodiment, an x-ray source **43** and an x-ray detector array **45**, as are known in the field of computed tomography. The source **43** and the detector **45** are positioned on opposite sides of the ring. In certain embodiments, the source and detector rotate around the interior of the housing in coordination with each another to perform an imaging scan of an object located within the bore **41**. In the embodiment of FIG. 8, both the source and the detector are mounted to a rotor **47**, and the rotor **47** is rotated within the gantry ring **40** to effect the x-ray scanning. A motor and drive mechanism can controllably rotate the rotor within the ring **40**, as is known in the art. Electrical signals, including for example, electrical power and control signals to the imaging equipment, and data signals from the imaging equipment, can be passed between the rotor **47** and the rest of the imaging system via a slip ring or cable system, or via any manner known in the art. In some embodiments, at least some of the signals can be passed via a wireless link between the control system and the imaging equipment on the rotor. Also, in some embodiments, all or a portion of the electrical power for the imaging equipment can be provided by a power supply located on the rotor **47**, such as a rechargeable battery-based power supply.

The outer shell or housing of the gantry ring **40** can be comprised of any sufficiently rigid and strong material, such as high-strength plastic, metal, carbon fiber and the like. The outer diameter of the ring **40** can be relatively small to improve the portability of the system **100**. In a preferred embodiment, the outer diameter of the ring **40** is less than about 70 inches, and in one embodiment is about 66 inches. In addition, the interior diameter of the ring **40**, or bore **41** diameter, can be sufficiently large to allow for the widest variety of patient support tables to fit inside the bore, and to facilitate access to a subject located inside the bore. In one embodiment, the bore diameter of the gantry ring **40** is greater than about 38 inches, and can be between about 40 and 50 inches. In one exemplary embodiment, the bore has a diameter of about 42 inches.

FIG. 9 is a side view of the gantry ring **40**. As can be seen from FIG. 9, the gantry ring **40** generally has a narrow profile which is consistent with the portability of the system. This can also help facilitate the mobility of the system, such as in a transport mode, as discussed below. In one embodiment, the width of the gantry ring **40** is less than about 17 inches, and can be about 15 inches or less.

Turning now to FIGS. 10A, 10B, 11A and 11B, the imaging system **100** is illustrated in an imaging position and a transport position. FIGS. 10A and 10B are side and top views, respectively, of the imaging system **100** in an imaging position. In this position, a tabletop support **60**, shown in phantom, is mounted to the pedestal **50** and extends from the pedestal **50** in a cantilevered manner in the direction of the gantry ring **40**. The gantry ring **40** is oriented generally perpendicular to the length of the base **20**, and the bore **41** imaging axis **80** faces generally towards the pedestal **50** and parallel to the length of the base **20**. At least a portion of the tabletop support **60** extends inside the bore **41**, such that an object on the tabletop support **60** can be imaged using the imaging equipment in the gantry ring **40**. As previously discussed, the gantry ring **40** can translate along the length of the base **20** to obtain images of the object along the imaging axis **80**. In FIGS. 11A and 11B, the imaging system **100** is in a transport position. The tabletop support **60** has been removed from the imaging area. In the transport position, the gantry ring **40** is oriented generally parallel to, or in-line with, the length of the base **20**. The bore **41**

imaging axis **80** is now generally perpendicular to the length of the base **20**. The profile of the system **100** is thus dramatically reduced in comparison to the imaging position, such that the system in a transport position is typically only as wide as the width of the base **20** and pedestal **50**.

This advantageously allows the system **100** to be more easily transported through narrow doors and hallways. The imaging system **100** can easily switch between an imaging position and a transport position, and vice versa, by rotating the gantry ring **40** with respect to the base **20**. This can be done by rotating the gimbal support **30**, which carries the gantry ring **40**, on the base **20**. The gantry ring **40** can be rotatable with respect to the base **20** at least about 90 degrees to switch between a transport position and an imaging position. In certain embodiments, the gantry **40** can rotate more than 90 degrees, including, for example, 180 degrees, 270 degrees, 360 degrees or more, relative to the base **20**. Further, the rotation of the gantry ring **40** with respect to the base can be bi-directional (i.e., both clockwise and counter-clockwise).

As seen in FIGS. **11A** and **11B**, the tabletop support **60** used for imaging applications is at least partially removed from the imaging area when the system **100** is in a transport mode. This is required in order to provide sufficient clearance for the gantry ring **40** to rotate from an imaging position to the narrower transport configuration. In certain embodiments, the tabletop support **60** is removed from the imaging area by detaching the entire tabletop support **60**, or a portion thereof, from the pedestal **50**. In other embodiments, the tabletop support **60** can be removed from the imaging area by other means, such as by sliding the tabletop support out of the imaging area, folding the tabletop support over to provide sufficient clearance for the gantry ring, by retracting a portion of the tabletop support, such as by an accordion- or telescoping-action, or by a combination of the above.

In one embodiment, the imaging system **100** is configured to receive a plurality of different tabletop support **60** structures, wherein different tabletop supports **60** are procedure-specific and customized to particular applications. The tabletop supports **60** can be conventional radiological tables, and can also comprise true surgical and trauma tables. The tabletop supports **60** can also comprise chairs to permit imaging of a patient in a seated position. FIGS. **12-14** illustrate various examples of tabletop supports **60** that can be attached to the pedestal **50** for an imaging operation. FIG. **12** illustrates a flat, operating tabletop support **60** that is mounted to the pedestal **50** and cantilevered into the imaging area. The tabletop support **60** can be wholly or partially radiolucent. FIG. **13** illustrates a modular tabletop support **60** that includes sections **61** that can be added to and removed from the tabletop support, and oriented relative to one another, to provide a wide variety of patient orientations. FIG. **14** illustrates a tabletop support **60** in the form of a chair that allows imaging of a seated patient. This configuration permits the imaging of a patient's chest area while in a seated position. The chair can be rotatable on the pedestal **50** at least 90 degrees, and in some cases 180 degrees or more, from an imaging position to a position that allows greater access to the patient by medical professionals.

In one embodiment, as shown in FIGS. **15A-15C**, the tabletop support **60** is transported to the imaging system **100** on a mobile cart **90**. A patient can be pre-positioned and prepped on the cart **90** and then moved to the imaging system **100**. The entire tabletop support **60** can then be moved over and locked onto the top of pedestal **50** with the patient already in position for imaging and/or a medical

procedure. As shown in FIG. **15B**, the cart **90** is released from the tabletop support **60**, and the tabletop support **60** is positioned inside the gantry ring **40** for an imaging application. The positioning of the tabletop support **60** within the system **100** can include any or all of the tabletop support movements previously described, including, for example, the z-axis and x-axis tabletop translation relative to the pedestal **50**, the up/down y-axis motion of the pedestal **50**, the y-axis rotation of the pedestal **50**, as well as a multi-axis tilt motion of the tabletop relative to the pedestal. Following the imaging procedure, the tabletop support **60**, along with the imaged subject, can be unlocked from the pedestal **50** and removed from the imaging system **100** via the cart **90**, as shown in FIG. **15C**. Alternatively, the tabletop support **60** can remain attached to the pedestal **50** while a medical procedure is performed on the imaged subject. When an imaging subject is undergoing a procedure, the gimbal support **30** and the gantry ring **40** can be translated to either the furthest distal or the furthest proximal position on the base **20**, in a "park" mode, to provide the greatest amount of access to the patient by medical professionals. In one embodiment, the gimbal support **30** and gantry ring **40** can translate along substantially the full length of the base **20** between the pedestal **50** and the distal end of the base, to maximize both the area over which the subject can be imaged and the area in which the imaging subject can be freely accessed when not being imaged.

It will be understood that virtually any type of tabletop support structure can be used in the present imaging system. For example, the present imaging system can utilize medical tables, and related accessories, of the type described in the JUPITER system brochure (November 2008) from TRUMPF Medezin Systeme GmbH & Co. KG of Puchheim, Germany, the entire contents of which are incorporated herein by reference. Furthermore, although the present embodiments illustrate 30 tabletop supports that can be used for medical imaging of human patients, it will be understood that the present invention encompasses any suitable tabletop support structure, including those designed for or suitable to support non-human subjects and non-living objects and materials.

Turning now to FIG. **16**, an embodiment of the invention is illustrated that includes a cantilevered tabletop support **60** with a pole **61** to provide additional support for the distal, cantilevered end of the tabletop support **60**. The pole **61** can be attached to the base **20**, and in certain embodiments, the pole **61** can extend from and retract wholly or partially into the base **20**, such as in a telescoping manner.

FIG. **17** illustrates an embodiment of the invention in which a tabletop support **60** is mounted directly to the distal end of the base **20**. In this embodiment, the tabletop support **60** comprises a chair that enables imaging of a patient in a sitting position.

FIG. **18** illustrates a helical scanning imaging application of the present invention. The imaging equipment (e.g., x-ray source and detector) rotate around the interior of the gantry ring **40** to obtain imaging data, while the gantry ring **40** and gimbal support **30** simultaneously translate along the base **20**. The arrow **111** indicates the path of the imaging equipment around the patient in a helical scan. The present imaging system is thus able to obtain true helical scan x-ray CT images, as are well-known in the art.

FIG. **19** is a side view of an embodiment of the present imaging system **100** in which the gantry ring **40** is tilted on the gimbal support **30**. A patient is supported partially on tabletop support **60** and partially on a specialized support **70** that enables the patient to be imaged in a stirrup position.

The specialized support 70 further includes a medical device 71 for performing a medical procedure on the patient. The present system thus enables medical personnel to obtain high-quality images of the patient, including 3D tomographic reconstructions, while performing a medical procedure on the patient. The present system is particularly advantageous, for example, for performing brachytherapy.

It will be understood that the imaging systems described herein may be constructed of any sufficiently rigid and strong materials such as high-strength plastic, metal, carbon fiber and the like, as well as combinations of the same.

The advantages of the present invention include, without limitation, that the present imaging systems in certain embodiments are portable and exceedingly easy to transport. Embodiments of present imaging system are easy to move into a hospital, office or elevator because the device is relatively small and lightweight. Moving such a device typically requires only a single person, even when taking the system up or down a ramp. Further, certain embodiments of the system can pass through most standard doorways without requiring any widening of the doorways. Further, the system can easily be moved from spot to spot once inside a room.

In one aspect, the present invention is an imaging system in which an imaging gantry ring can tilt, rotate or translate along a mobile base with a detachable or movable patient tabletop support, thus allowing the apparatus to be easily transportable. The rotation and tilt axes of the gantry ring permits the gantry ring to be oriented generally perpendicular to the mobile base, allowing a cantilevered tabletop support to pass through the center of the gantry ring in certain imaging modes, and further allows the gantry ring to be rotated generally in-line with the mobile base in a transport mode, thus allowing the apparatus to be as narrow as possible to pass through hallways, corridors or elevators.

Those of ordinary skill will understand and appreciate the existence of variations, combinations, and equivalents of the specific embodiments, methods, and examples disclosed herein. The invention should therefore not be limited except by the scope and spirit of the appended claims.

What is claimed:

1. An x-ray medical imaging system, comprising:

a mobile base with one or more wheels;

a transport motor that is geared into the one or more wheels to propel the x-ray imaging system across a floor in a transport mode;

a pedestal mounted to the mobile base and configured to support a patient support above the base;

an imaging gantry mounted to the mobile base, the imaging gantry containing an x-ray source and a detector and defining an imaging bore;

a motorized system that translates the imaging gantry along a length of the mobile base relative to the pedestal in an imaging mode; and

a patient support mounted to the pedestal such that the patient support extends at least partially into the imaging bore of the imaging gantry, the patient support configured to support the patient in a stirrup position while the x-ray source and detector obtain images of the patient in the imaging mode.

2. The x-ray medical imaging system of claim 1, wherein the system comprises an x-ray computed tomography (CT) system, and the x-ray source and detector rotate around the interior of the imaging gantry while the imaging gantry translates along the length of the support to obtain helical scan x-ray CT images.

3. The x-ray medical imaging system of claim 1, further comprising a computer control system that is coupled to the motorized system for controlling the translation motion of the imaging gantry along the length of the base.

4. The x-ray medical imaging system of claim 3, further comprising a second motorized system that tilts the imaging gantry relative to the base and the patient support under control of the computer control system.

5. The x-ray medical imaging system of claim 1, wherein the inner bore diameter is between about 40 and 50 inches.

6. The x-ray medical imaging system of claim 1, wherein the patient support is removeable from the pedestal, and the pedestal is configured to support a plurality of interchangeable patient supports.

7. The x-ray medical imaging system of claim 1, wherein the x-ray source and the detector are mounted to a rotor supported for rotation about the imaging bore.

8. The x-ray medical imaging system of claim 7, wherein at least one of the x-ray source and the detector are powered by a rechargeable battery-based power supply located on the rotor.

9. The x-ray medical imaging system of claim 7, wherein data signals from at least one component mounted to the rotor are sent to a computer located off of the rotor via a wireless link.

10. The x-ray medical imaging system of claim 1, wherein the patient support has a first surface; and

wherein the imaging gantry is rotatable relative to the base at least about 90 degrees with respect to an axis extending generally normal to the first surface of the base.

11. The x-ray medical imaging system of claim 10, further comprising a gimbal mounted to the base and comprising a pair of arms extending away from the first surface of the base and connecting to opposite sides of the imaging gantry.

12. The x-ray medical imaging system of claim 11, wherein the gimbal and the imaging gantry rotate together relative to the base and translate together along the length of the base.

13. The x-ray medical imaging system of claim 11, wherein the imaging gantry is pivotable with respect to the arms of the gimbal to tilt the gantry relative to the base.
