An HVAC system includes a high-pressure subsystem and a low-pressure subsystem. After determining that refrigerant leak diagnostics should be performed, a controllable valve is closed between a condenser and compressor of the HVAC system. The compressor then operates until a predetermined input refrigerant pressure is reached. After the predetermined input refrigerant pressure is reached, operation of the compressor is stopped. After stopping operation of the compressor and waiting at least a predetermined wait time, the pressure in the low-pressure subsystem of the HVAC system is monitored. A rate of change of the pressure in the low-pressure subsystem is determined. If the rate of change is negative and a magnitude of the rate of change is greater than a threshold value, a leak location is determined to be in the low-pressure subsystem.

**HVAC SYSTEM LEAK DETECTION****CROSS-REFERENCE TO RELATED APPLICATION**

This application is a continuation of U.S. patent application Ser. No. 18/153,237 filed Jan. 11, 2023, now U.S. Pat. No. 11,898,764 issued Feb. 13, 2024, which is a continuation of U.S. patent application Ser. No. 17/352,077, filed Jun. 18, 2021, now U.S. Pat. No. 11,578,887 issued Feb. 14, 2023, entitled "HVAC SYSTEM LEAK DETECTION" which are incorporated herein by reference.

**TECHNICAL FIELD**

The present disclosure relates generally to heating, ventilation, and air conditioning (HVAC) systems and methods of their use. In particular, the present disclosure relates to HVAC system leak detection.

**BACKGROUND**

Heating, ventilation, and air conditioning (HVAC) systems are used to regulate environmental conditions within an enclosed space. Air is cooled via heat transfer with refrigerant flowing through the HVAC system and returned to the enclosed space as cooled conditioned air. Leakage of the refrigerant can result in decreased system performance.

**SUMMARY OF THE DISCLOSURE**

The leakage of refrigerant, or loss of charge, from an HVAC system can result in decreased system performance (e.g., loss of desired cooling, increased energy consumption, etc.), eventual damage to system components, and potential risk to people and the environment. For example, the cooling capacity of an HVAC system may decrease as refrigerant leaks from the system. The leaked refrigerant may be harmful to people and the environment. Previous technology used to detect refrigerant leaks fails to provide information about the location of a leak. Because of this, extensive diagnostics must be performed by specially trained technicians to search for the location of a refrigerant leak. This can result in significant delays in locating and repairing a refrigerant leak and corresponding downtimes during which cooling cannot be provided to a space. In some cases, even small refrigerant leaks, which may go undetected and/or unlocated by previous technology, may pose a risk to people and/or the environment. For instance, certain HVAC systems use flammable refrigerant. Flammable refrigerant may leak, causing unsafe concentrations of gas to be dispersed within an occupied space. In addition to the risk of fire, unsafe concentrations of gas within the space may be harmful to the health of the space's occupants and particularly to the elderly and sick.

This disclosure provides technical solutions to the problems of previous technology, including those described above. For example, this disclosure recognizes that the ability to automatically and reliably detect a leak and its location within an HVAC system can decrease maintenance downtimes, increase the lifetime of the HVAC system and its components, and improve the safety of people and the environment. As described further below, if a possible leak is detected, a valve may be closed between high-pressure and low-pressure subsystems of the HVAC system (e.g., between a condenser and evaporator). The HVAC system's compressor can then be operated until a predetermined input

refrigerant pressure is reached for the compressor. Operation of the compressor is then stopped, and the pressure of the low-pressure side of the HVAC system is monitored for a period of time. This disclosure recognizes that the rate of change of this monitored pressure can be used to determine a leak location of the refrigerant (e.g., whether refrigerant is leaking from the low-pressure or high-pressure subsystem of the HVAC system).

Embodiments of this disclosure may improve the speed and reliability with which refrigerant leaks can be detected and appropriate maintenance can be performed. As such, the system described in this disclosure may significantly decrease downtimes during which cooling cannot be provided by an HVAC system. Embodiments of this disclosure may also improve the overall safety of HVAC systems and the spaces cooled by HVAC systems. For example, refrigerant may be primarily held in a high-pressure subsystem of the HVAC system that is in an outdoor space when a refrigerant leak is detected. Since the majority of the refrigerant is held in the outdoor space, accumulation of leaking refrigerant in an indoor living space is reduced or prevented. Certain embodiments may include none, some, or all of the above technical advantages. One or more other technical advantages may be readily apparent to one skilled in the art from the figures, descriptions, and claims included herein.

In an embodiment, an HVAC system includes a high-pressure subsystem and a low-pressure subsystem. The high-pressure subsystem includes a condenser operable to receive refrigerant and transfer heat from the refrigerant to a flow of outdoor air, thereby generating a cooled refrigerant, and a controllable valve positioned in a refrigerant conduit connecting the condenser to an evaporator. The low-pressure subsystem includes the evaporator operable to receive the cooled refrigerant and transfer heat from a flow of air to the cooled refrigerant, a compressor operable to compress the refrigerant, and a pressure sensor operable to measure a refrigerant pressure in the low-pressure subsystem. A controller is communicatively coupled to the pressure sensor, the compressor, and the controllable valve. The controller determines that refrigerant leak diagnostics should be performed for the HVAC system (e.g., based on a timer/schedule and/or a detection of the possible leak of refrigerant). After determining that the refrigerant leak diagnostics should be performed, the controllable valve is closed. The compressor then operates until a predetermined input refrigerant pressure is reached. After the predetermined input refrigerant pressure is reached, operation of the compressor is stopped (e.g., the compressor is turned off or to a speed of zero). After stopping operation of the compressor and waiting at least a predetermined wait time, the pressure in the low-pressure subsystem of the HVAC system is monitored for a period of time. A rate of change of the pressure in the low-pressure subsystem is determined for the period of time. If the rate of change is negative and a magnitude of the rate of change is greater than a threshold value, a leak location of the refrigerant is determined to be in the low-pressure subsystem of the HVAC system. However, if one or both of the rate of change is not negative and the magnitude of the rate of change is not greater than a threshold value, the leak location of the refrigerant may be in the high-pressure subsystem of the HVAC system.

**BRIEF DESCRIPTION OF THE DRAWINGS**

For a more complete understanding of the present disclosure, reference is now made to the following description, taken in conjunction with the accompanying drawings, in which:

FIG. 1 is a diagram of an example HVAC system configured for leak detection and diagnosis;

FIG. 2 is a plot of an example measured low-side pressure over time for leak detection; and

FIG. 3 is a flowchart of an example method of operating the HVAC system of FIG. 1 to detect a refrigerant leak and determine a system diagnosis.

#### DETAILED DESCRIPTION

Embodiments of the present disclosure and its advantages are best understood by referring to FIGS. 1-3 of the drawings, like numerals being used for like and corresponding parts of the various drawings.

As described above, prior to this disclosure, there was a lack of tools for reliably detecting and locating/diagnosing refrigerant leaks. The system described in this disclosure facilitates the detection of refrigerant leaks and the proactive determination of a likely diagnosis of which portion, or subsystem, of the HVAC system is leaking refrigerant. Once a location of the leak is determined, a system diagnosis including this information may be provided proactively to an occupant of the space and/or a service provider, such that appropriate maintenance can be provided more rapidly than was possible using previous leak detection technology.

As used in the present disclosure, a “saturated” refrigerant refers to a fluid in the liquid state that is in thermodynamic equilibrium with the vapor state of the fluid for a given pressure. A “saturated” refrigerant is said to be at the saturation temperature for a given pressure. If the temperature of a saturated liquid is increased above the saturation temperature, the saturated liquid generally begins to vaporize. A “superheated” refrigerant refers to a fluid in the vapor state that is heated to a temperature that is greater than the saturation temperature of the fluid at a given pressure.

#### HVAC System

FIG. 1 is a schematic diagram of an example HVAC system 100 configured to detect and locate system faults, such as a leak of refrigerant. The HVAC system 100 conditions air for delivery to a space. The space may be, for example, a room, a house, an office building, a warehouse, or the like. In some embodiments, the HVAC system 100 is a rooftop unit (RTU) that is positioned on the roof of a building, and conditioned air 122 is delivered to the interior of the building. In other embodiments, portion(s) of the HVAC system 100 may be located within the building and portion(s) outside the building. The HVAC system 100 may be configured as shown in FIG. 1 or in any other suitable configuration. For example, the HVAC system 100 may include additional components or may omit one or more components shown in FIG. 1.

The HVAC system 100 includes a working-fluid conduit subsystem 102, a compressor 106, a condenser 108, an outdoor fan 110, a check valve 114, an expansion device 116, an evaporator 118, a blower 130, sensors 134, 136, 138, 140, 142, 146, a return air filter 144, one or more thermostats 148, and a controller 154. As described in greater detail below, the controller 154 of the HVAC system 100 is generally configured to determine that refrigerant leak diagnostics should be performed, for instance, based on a timer/schedule or the detection of a likely leak of refrigerant (e.g., based on a change in low-side pressure 170 or high-side pressure 190 and/or a gas leak signal 168). If it is determined that the refrigerant leak diagnostics should be performed, the expansion valve 116 may be closed between the high-pressure subsystem 104a and low-pressure subsystem 104b of the HVAC system 100. The compressor 100 is

then operated until a predetermined input refrigerant pressure (e.g., low-side pressure 170 measured by sensor 138) is reached. Operation of the compressor 106 is then stopped, and the low-side pressure 170 of the low-pressure subsystem 104b of the HVAC system 100 is monitored for a period of time. The rate of change 172 of this monitored low-side pressure 170 is used to determine a leak location of the refrigerant (e.g., whether refrigerant is leaking from the low-pressure subsystem 104b or high-pressure subsystem 104a of the HVAC system 100). Operation of the controller 154 is described in greater detail below and with respect to the method of FIG. 3. In some cases, the system diagnosis 182 may be automatically provided to a service provider 188 (e.g., a maintenance provider). This may facilitate proactive repairs of the HVAC system 100, such that there is limited or no downtime during which desired heating or cooling is not available.

The working-fluid conduit subsystem 102 facilitates the movement of a refrigerant through a refrigeration cycle such that the refrigerant flows as illustrated by the dashed arrows in FIG. 1. The working-fluid conduit subsystem 102 includes conduit, tubing, and the like that facilitates the movement of refrigerant between components of the HVAC system 100. The refrigerant may be any acceptable refrigerant including, but not limited to, fluorocarbons (e.g. chlorofluorocarbons), ammonia, non-halogenated hydrocarbons (e.g. propane), hydrofluorocarbons (e.g. R-410A), or any other suitable type of refrigerant. In some cases, the refrigerant may be flammable or pose a risk to occupants of the space cooled by the HVAC system 100.

The HVAC system 100 generally includes a “high side” or high-pressure subsystem 104a and a “low side” or low-pressure subsystem 104b. The high-pressure subsystem 104a generally includes components and portions of the working-fluid conduit subsystem 102 that contain refrigerant at a relatively high pressure (e.g., after the refrigerant is pressurized, or compressed, by the compressor 106). The low-pressure subsystem 104b includes components and portions of the working-fluid conduit subsystem 102 that contain refrigerant at a relatively low pressure (e.g., after the refrigerant is expanded by the expansion device 116). In some cases, the high-pressure subsystem 104a is primarily located outdoors, while the low-pressure subsystem 104b may be located indoors.

The HVAC system 100 includes a compressor 106, a condenser 108, and a fan 110. In some embodiments, the compressor 106, condenser 108, and fan 110 are combined in an outdoor unit while at least certain other components of the HVAC system 100 may be located indoors (e.g., components of the low-pressure subsystem 104b). The compressor 106 is coupled to the working-fluid conduit subsystem 102 and compresses (i.e., increases the pressure of) the refrigerant. The compressor 106 may be a single-speed, variable-speed, or multiple stage compressor. A single-speed compressor is generally configured to operate at a single, predefined speed. A variable-speed compressor is generally configured to operate at different speeds to increase the pressure of the refrigerant to keep the refrigerant moving along the working-fluid conduit subsystem 102. In the variable-speed compressor configuration, the speed of compressor 106 can be modified to adjust the cooling capacity of the HVAC system 100. Meanwhile, in the multi-stage compressor configuration, one or more compressors can be turned on or off to adjust the cooling capacity of the HVAC system 100.

The compressor 106 is in signal communication with the controller 154 using wired and/or wireless connection. The

controller **154** provides commands or signals to control operation of the compressor **106** and/or receives signals from the compressor **106** corresponding to a status of the compressor **106**. For example, the controller **154** may transmit signals to adjust compressor speed and/or staging. The controller **154** may operate the compressor **106** in different modes corresponding, for example, to an operating mode indication **150** (e.g., a heating, cooling, or diagnostic mode), to load conditions (e.g., the amount of cooling or heating required by the HVAC system **100**), to a difference between a setpoint temperature and an indoor air temperature, and the like.

A check valve **114** may be positioned at the outlet of the compressor **106**. The check valve prevents backflow of refrigerant into the compressor **106** when the compressor **106** is not operated (e.g., as in during at least a portion of the diagnostic operations described in this disclosure). The check valve **114** may be operated based on a pressure of refrigerant in the conduit **102** connecting the compressor **106** to the condenser **108** relative to the pressure of refrigerant in the compressor **106**. For example, if the pressure in the conduit **102** exceeds the pressure in the condenser **106**, then the check valve **114** may automatically close to prevent backflow of refrigerant into the compressor **106**. In some cases, the check valve **114** may be controlled by the controller **154**. For example, the check valve **114** may be in signal communication with the controller **154** using wired and/or wireless connection. In such cases, the controller **154** provides commands or signals to control operation of the check valve **114**. For example, the controller **154** may cause the check valve **114** to be appropriately adjusted to prevent the refrigerant from flowing into the outlet of the compressor **106** after operation of the compressor **106** is stopped for refrigerant leak diagnostics.

The condenser **108** is generally located downstream of the compressor **106** and is configured, when the HVAC system **100** is operating in a cooling mode, to remove heat from the refrigerant. The fan **110** is configured to move air **112** across the condenser **108**. For example, the fan **110** may be configured to blow outside air through the condenser **108** to help cool the refrigerant flowing therethrough. In the cooling mode, the compressed, cooled refrigerant flows from the condenser **108** toward the expansion device **116**.

The expansion device **116** is coupled to the working-fluid conduit subsystem **102** downstream of the condenser **108** and is configured to remove pressure from the refrigerant. The expansion device **116** is generally a controllable valve positioned in refrigerant conduit of the working-fluid conduit subsystem **102** that connects the condenser **108** to the evaporator **118**. In this way, the refrigerant is delivered to the evaporator **118** and receives heat from airflow **120** to produce a conditioned airflow **122** that is delivered by a duct subsystem **124** to the conditioned space. In general, the expansion device **116** may be a valve such as an expansion valve or a flow control valve (e.g., a thermostatic expansion valve) or any other suitable valve for removing pressure from the refrigerant while, optionally, providing control of the rate of flow of the refrigerant. In some cases, the expansion device **116** may include two devices, for example, a thermostatic expansion valve (TXV) with a solenoid valve located upstream of the TXV. The expansion device **116** may be in communication with the controller **154** (e.g., via wired and/or wireless communication) to receive control signals for opening and/or closing associated valves and/or provide flow measurement signals corresponding to the rate of refrigerant flow through the working-fluid conduit subsystem **102**.

The evaporator **118** is generally any heat exchanger configured to provide heat transfer between air flowing through (or across) the evaporator **118** (i.e., air **120** contacting an outer surface of one or more coils of the evaporator **118**) and refrigerant passing through the interior of the evaporator **118**, when the HVAC system **100** is operated in the cooling mode. The evaporator **118** may include one or more circuits. The evaporator **118** is fluidically connected to the compressor **106**, such that refrigerant generally flows from the evaporator **118** to the compressor **106**. A portion of the HVAC system **100** is configured to move air **120** across the evaporator **118** and out of the duct subsystem **124** as conditioned air **122**. In some embodiments, the HVAC system **100** may include a heating element (not shown for clarity and conciseness). The heating element is generally any device for heating the flow of air **120** and providing heated air **122** to the conditioned space, when the HVAC system **100** operates in a heating mode.

Return air **126**, which may be air returning from the building, air from outside, or some combination, is pulled into a return duct **128**. An inlet or suction side of the blower **130** pulls the return air **126**. The return air **126** may pass through an air filter **144**. The air filter **144** is generally a piece of porous material that removes particulates from the return air **126**. As described further below, sensor(s) **146** may be located on each side of the air filter **144** and configured to measure an air pressure drop **180** across the air filter **144**. The air pressure drop **180** may be used to determine when the air filter **144** is blocked by accumulated particulates and should be changed. The blower **130** discharges air **120** into a duct **132** such that air **120** crosses the evaporator **118** to produce conditioned air **122**. The blower **130** is any mechanism for providing a flow of air through the HVAC system **100**. For example, the blower **130** may be a constant-speed or variable-speed circulation blower or fan. Examples of a variable-speed blower include, but are not limited to, belt-drive blowers controlled by inverters, direct-drive blowers with electronic commuted motors (ECM), or any other suitable type of blower.

The blower **130** is in signal communication with the controller **154** using any suitable type of wired and/or wireless connection. The controller **154** is configured to provide commands and/or signals to the blower **130** to control its operation. For example, the controller **154** may receive an indication of the blower status **178** indicating whether the blower is operating as intended. Generally, when functioning as intended, the blower **130** provides airflow **120** across the evaporator **118**, but the blower may not provide the appropriate or expected airflow **120** when the blower **130** is not functioning as intended. The controller **154** may include the blower status **178** in the system diagnosis **182** to improve the system diagnosis **182**. For example, this may improve the speed with which a malfunctioning blower **130** can be repaired.

The HVAC system **100** includes one or more of the sensors **134**, **136**, **138**, **140**, **142**, **146** illustrated in FIG. 1. The sensors **134**, **136**, **138**, **140**, **142**, **146** are in wired and/or wireless signal communication with controller **154**. Signals corresponding to the properties measured by sensors **134**, **136**, **138**, **140**, **142**, **146** are provided to the controller **154**. In some embodiments, one or more of the sensors **134**, **136**, **138**, **140**, **142**, **146** or another sensor integrated with the HVAC system **100** may be an internet-of-things (IOT) device. For example, one or more of the sensors **134**, **136**, **138**, **140**, **142**, **146** may communicate wirelessly with the controller **154** (e.g., via a wireless network associated with the conditioned space). In other examples, the HVAC system

**100** may include other sensors (not shown for clarity and conciseness) positioned and configured to measure any other property associated with operation of the HVAC system **100** (e.g., the temperature and/or relative humidity of air at one or more locations within the conditioned space and/or out-  
doors).

Sensors **134** and **136** are positioned proximate or inside the evaporator **118** to measure properties of the refrigerant flowing therethrough. For example, sensors **134**, **136** may measure temperatures and/or pressures of the refrigerant at different points in the evaporator **118**. The measured temperatures and/or pressures may be used by the controller **154** to determine a superheat (SH) **164**. SH **164** is the difference between the temperature of refrigerant exiting the evaporator **118** (e.g., measured by sensor **136**) and the vaporization temperature of the refrigerant in the evaporator **118** (e.g., measured via temperature or pressure measured by sensor **134**). For example, the first evaporator sensor **134** may be positioned and configured to measure a saturated suction temperature (SST) **162** of the refrigerant in the evaporator **118**, while the second sensor **136** may be positioned and configured to measure a superheated vapor temperature of the refrigerant in the evaporator **118**. The controller **154** may determine the SH **164** based on a difference between the SST **162** and the superheated vapor temperature. If both the SST **162** is less than a threshold value **166** and the SH **164** is less than a threshold value **166**, a refrigerant leak may be detected by the controller **154**.

Sensor **138** is located proximate the inlet of the compressor **106** or in the portion of the working-fluid conduit **102** leading into the inlet of the compressor **106**. While in the example of FIG. 1, the sensor **138** is shown relatively near the inlet of the compressor **106**, this sensor **138** could be located further upstream from the inlet of the compressor **106** (e.g., nearer the outlet of the evaporator **118**). The controller **154** uses a signal from the sensor **138** to determine the low-side pressure **170**. The low-side pressure **170** is a pressure of refrigerant in the low-pressure subsystem **104b** of the HVAC system **100**. In some cases, the SST **162** may be determined from a pressure (e.g., low-side pressure **170**) measured by sensor **138**. In some embodiments, the sensor **138** includes a pressure switch. A pressure switch signal **176** provided to the controller **154** by such a pressure switch may be used to determine when the low-side pressure **170** is less than a threshold value **166** for stopping operation of the compressor **106** in order to perform leak diagnostics, as described further below and with respect to FIG. 3.

Sensor **140** measures a high-side pressure **190**. The high-side pressure **190** is the pressure of the refrigerant in the high-pressure subsystem **104a** of the HVAC system **100**. While in the example of FIG. 1, the sensor **140** is shown between the outlet of the compressor **106** and the inlet of the condenser **108**, this sensor **140** could be located at another position in the high-pressure subsystem **104a** of the HVAC system **100** (e.g., proximate or downstream of the outlet of the condenser **108**). The controller **154** uses a signal from the sensor **140** to determine the high-side pressure **190**.

Sensor **142** is positioned and configured to measure a discharge air temperature of airflow **122** or a temperature of air provided to the space conditioned by the HVAC system **100**. Sensor(s) **146** may be located on each side of the air filter **144** and configured to measure an air pressure drop **180** across the air filter **144**. The air pressure drop **180** may be used to determine when the air filter **144** is blocked and/or should be changed. This information may be used to improve the system diagnosis **182** determined by the con-

troller **154** (e.g., by including an indication of a blockage of the air filter **144** in the system diagnosis **182**).

Information from sensors **134**, **136**, **138**, **140**, **142** may be used to determine that a refrigerant leak is detected. For example, if one or both of the low-side pressure **170** and the high-side pressure **190** decreases below a corresponding threshold **166**, a leak may be detected. In some cases, one or more of the sensors **134**, **136**, **138**, **140**, **142** may include a leak detection device, such as a gas sensor configured to detect refrigerant gas that is emitted from the HVAC system **100**. Such a sensor may provide a gas leak signal **168** to the controller **154** to indicate that a refrigerant leak is detected and that leak diagnostics are needed to determine a location of the refrigerant leak.

The HVAC system **100** includes one or more thermostats **148**, for example, located within the conditioned space (e.g. a room or building). The thermostat(s) **148** are generally in signal communication with the controller **154** using any suitable type of wired and/or wireless connection. In some embodiments, one or more functions of the controller **154** may be performed by the thermostat(s) **148**. For example, the thermostat **148** may include the controller **154**. The thermostat(s) **148** may include one or more single-stage thermostats, one or more multi-stage thermostat, or any suitable type of thermostat(s). The thermostat(s) **148** are configured to allow a user to input a desired temperature or temperature setpoint for the conditioned space and/or for a designated space or zone, such as a room, in the conditioned space. The thermostat(s) generally include or are in communication with a sensor for measuring an indoor air temperature (e.g., sensor **142**).

The controller **154** may use information from the thermostat **148** such as the temperature setpoint, indoor air temperature, and/or mode indication **150** for controlling the compressor **106**, the blower **130**, and the fan **110**. In some embodiments, a thermostat **148** includes a user interface and/or display for displaying information related to the operation and/or status of the HVAC system **100**. For example, the user interface may display operational, diagnostic, and/or status messages and provide a visual interface that allows at least one of an installer, a user, a support entity, and a service provider to perform actions with respect to the HVAC system **100**. For example, the user interface may provide for display of the mode indication **150**, which indicates a current operating mode of the HVAC system **100**, such as whether the HVAC system **100** is operating to provide cooling or heating or if the HVAC system **100** is temporarily operating in a diagnostic mode (e.g., with the compressor **106** turned off for a period of time). The user interface may display an alert **152**, for example, indicating a refrigerant leak is detected for the HVAC system **100**. The user interface may display a system diagnosis **182** determined by the controller **154** based on outcomes of the leak diagnostics described below and with respect to FIG. 3. The system diagnosis **182** generally includes an indication of a refrigerant leak location **184** and/or a failed component **186** of the HVAC system **100** that was determined to have failed.

As described in greater detail below, the controller **154** is configured to determine a system diagnosis **182** for a detected refrigerant leak. The system diagnosis **182** may be presented on the display of the thermostat **148** and/or to a service provider **188** to ensure maintenance is performed rapidly and accurately with little or no downtime during which cooling is not available. The controller includes a processor **156**, memory **158**, and input/output (I/O) interface **160**. The processor **156** includes one or more processors operably coupled to the memory **158**. The processor **156** is

any electronic circuitry including, but not limited to, state machines, one or more central processing unit (CPU) chips, logic units, cores (e.g. a multi-core processor), field-programmable gate array (FPGAs), application specific integrated circuits (ASICs), or digital signal processors (DSPs) that communicatively couples to memory **158** and controls the operation of HVAC system **100**. The processor **156** may be a programmable logic device, a microcontroller, a micro-processor, or any suitable combination of the preceding. The processor **156** is communicatively coupled to and in signal communication with the memory **158**. The one or more processors are configured to process data and may be implemented in hardware or software. For example, the processor **156** may be 8-bit, 16-bit, 32-bit, 64-bit or of any other suitable architecture. The processor **156** may include an arithmetic logic unit (ALU) for performing arithmetic and logic operations, processor registers that supply operands to the ALU and store the results of ALU operations, and a control unit that fetches instructions from memory **158** and executes them by directing the coordinated operations of the ALU, registers, and other components. The processor **156** may include other hardware and software that operates to process information, control the HVAC system **100**, and perform any of the functions described herein (e.g., with respect to FIGS. **2** and **3**). The processor **156** is not limited to a single processing device and may encompass multiple processing devices. Similarly, the controller **154** is not limited to a single controller but may encompass multiple controllers.

The memory **158** includes one or more disks, tape drives, or solid-state drives, and may be used as an over-flow data storage device, to store programs when such programs are selected for execution, and to store instructions and data that are read during program execution. The memory **158** may be volatile or non-volatile and may include ROM, RAM, ternary content-addressable memory (TCAM), dynamic random-access memory (DRAM), and static random-access memory (SRAM). The memory **158** is operable (e.g., or configured) to store information used by the controller **154** and/or any other logic and/or instructions for performing the function described in this disclosure.

The I/O interface **160** is configured to communicate data and signals with other devices. For example, the I/O interface **160** may be configured to communicate electrical signals with components of the HVAC system **100** including the compressor **106**, fan **110**, expansion device **116**, sensors **134**, **136**, **138**, **140**, **142**, **146**, blower **130**, and thermostat(s) **148**. The I/O interface **160** may be configured to communicate with other devices and systems, such as the service provider **188**. The I/O interface **160** may provide and/or receive, for example, compressor speed signals blower speed signals, temperature signals, relative humidity signals, thermostat calls, temperature setpoints, environmental conditions, and an operating mode status for the HVAC system **100** and send electrical signals to the components of the HVAC system **100**. The I/O interface **160** may include ports or terminals for establishing signal communications between the controller **154** and other devices. The I/O interface **160** may be configured to enable wired and/or wireless communications.

In an example operation of HVAC system **100**, the HVAC system **100** starts up to operate in the cooling mode. For example, in response to the indoor temperature increasing above a temperature setpoint while the HVAC system **100** is set to operate in the cooling mode (e.g., based on mode indication **150**), the controller **154** may cause the compressor **106**, fan **110** and blower **130** to operate. During operation

of the HVAC system **100**, the controller **154** (e.g., the processor **156** of the controller **154**) determines refrigerant leak diagnostics should be performed. For instance, the controller **154** may determine that it has been at least a threshold time since the last leak diagnostics was run (e.g., based on a schedule and/or timer of the controller **154**). As another example, a possible leak of refrigerant may be detected from the HVAC system **100** that indicates refrigerant leak diagnostics should be performed. As described above, the possible refrigerant leak may be detected based on information from one or more of the sensors **134**, **136**, **138**, **140**, **142**. For instance, a drop in the low-side pressure **170** below a corresponding threshold **166**, a drop of the high-side pressure **190** below a corresponding threshold **166**, and/or receipt of a gas leak signal **168** may be used to determine the possible refrigerant leak. In some cases, after determining that the possible leak of refrigerant is detected, the controller **154** may cause display of a mode indication **150** on the thermostat **148** that indicates that the HVAC system **100** is operating in a diagnostic mode. During operation in the diagnostic mode, cooling or heating may not be available for a period of time. Providing this information to occupants of the space via the thermostat **148** may improve usability of the HVAC system **100**, such that occupants do not think another issue is causing the brief inability to perform cooling or heating.

After determining that the refrigerant leak diagnostics should be performed, the controller **154** causes the expansion valve **116** to close. For example, valve instructions **174** may be provided to close the expansion valve **116** (e.g., to close a solenoid valve of the expansion valve **116**). After the expansion valve **116** is closed, refrigerant cannot flow from the high-pressure subsystem **104a** into the low-pressure subsystem **104b**. The controller **154** then causes the compressor **106** to operate until a predetermined low-side pressure **170** is reached on the inlet side of the compressor **106**. For example, the compressor **106** may operate until the low-side pressure **170** measured by sensor **138** decreases to at least a threshold value **166**. After the predetermined low-side pressure **170** is reached, operation of the compressor **106** is stopped. If needed, the controller **154** may also adjust the check valve **114** after operation of the compressor **106** is stopped, such that the refrigerant from the high-pressure subsystem **104a** cannot backflow through the compressor **106** into the low-pressure subsystem **104b**. For example, the check valve **114** may be closed. In some cases, the check valve **114** is a one-way valve which prevents backflow of refrigerant into the compressor **106** without action from the controller **154**. At this point, a majority of the refrigerant may be present in the high-pressure subsystem **104a**, which is all or mostly outdoors, such that any leak of refrigerant from the low-pressure subsystem **104b** will present a decreased risk to occupants of the indoor space.

After a predetermined wait time (e.g., a threshold **166** wait time, or the waiting time **204** of FIG. **2**, described below), the controller **154** monitors the low-side pressure **170** for some time (e.g., the monitoring time **206** of FIG. **2**) and determines a rate of change **172** of the low-side pressure **170** over time. This rate of change **172** is used to determine whether the detected leak is occurring in the high-pressure subsystem **104a** or the low-pressure subsystem **104b**. For example, if the rate of change **172** is negative and a magnitude of the rate of change **172** is greater than a threshold value **166**, the controller **154** may determine that the leak location **184** of the refrigerant is in the low-pressure subsystem **104b** of the HVAC system **100**. Alternatively, if one or both of the rate of change **172** is not negative or the

## 11

magnitude of the rate of change 172 is not greater than the threshold value 166, the controller 154 may determine that the leak location 184 of the refrigerant may be in the high-pressure subsystem 104a. The controller 154 then determines the system diagnosis 182 that includes the determined leak location 184. The system diagnosis 182 may be displayed via the thermostat 148 and/or provided to the service provider 188, as described above.

To further illustrate the refrigerant leak diagnostics described above, FIG. 2 shows an example plot 200 of the low-side pressure 170 as a function of time beginning from when the compressor 106 is turned off. After the compressor is turned off, the controller 154 waits for a waiting time 204 to allow the low-side pressure 170 to equilibrate. The low-side pressure 170 may increase initially during the waiting time 204 because the temperature of the refrigerant may increase after the compressor 106 is turned off. The controller 154 then monitors the low-side pressure 170 for a monitoring time 206. During this monitoring time 206, the controller 154 may determine the rate of change 172 of the low-side pressure 170. The rate of change 172 may be determined, for example, as the change in pressure 208 over the monitoring time 206.

Returning to FIG. 1, in some cases, the controller 154 may also check the functioning of other components of the HVAC system 100 and include such findings in the system diagnosis 182. Information about functions of other system components may improve the determination of appropriate maintenance actions to take to ensure continued reliable operation of the HVAC system 100. For example, the controller 154 may determine the blower status 178 from information provided by the blower 130 (if this information is available). If the blower status 178 indicates that the blower 130 is not operating as intended, the blower 130 may be included as a failed component 186 in the system diagnosis 182. As another example, the controller 154 may detect a blockage of the air filter 144 if the air pressure drop 180 across the air filter 144 is greater than a threshold value 166. If such a blockage is detected, the air filter 144 may be indicated as a failed component 186 in the system diagnosis (e.g., because of the need to clean or replace the air filter 144).

Example Methods of HVAC System Prognostics and Diagnostics

FIG. 3 illustrates a method 300 of automatically locating and diagnosing a possible refrigerant leak in the HVAC system 100 of FIG. 1. The method 300 may be implemented using the processor 156, memory 158, and I/O interface 160 of the controller 154 of FIG. 1. The method 300 may begin at step 302 where the controller 154 determines whether refrigerant leak diagnostics should be performed. For example, the controller 154 may determine whether it has been greater than a threshold time since the last leak diagnostic was performed. For example, refrigerant leak diagnostics may be performed monthly, seasonally, or the like. As another example, refrigerant leak diagnostics may be performed when a possible refrigerant leak is detected. For example, the possible refrigerant leak may be detected based on information from one or more of the sensors 134, 136, 138, 140, 142. For instance, a drop in the low-side pressure 170 below a corresponding threshold 166, a drop of the high-side pressure 190 below a corresponding threshold 166, and/or receipt of a gas leak signal 168 may be used to determine the possible refrigerant leak. If refrigerant leak diagnostics should not be performed, the controller 154

## 12

returns to start. Otherwise, if refrigerant leak diagnostics should be performed, the controller 154 proceeds to step 304.

At step 304, the controller 154 causes display of a mode indication 150 on the thermostat 148 that indicates that the HVAC system 100 is operating in a diagnostic mode. During operation in the diagnostic mode, cooling or heating may not be available for a period of time. Providing this information to occupants of the space via the thermostat 148 may improve usability of the HVAC system 100, such that occupants do not think another issue is causing the brief inability to perform cooling or heating.

At step 306, the controller 154 causes the expansion valve 116 to close. For example, valve instructions 174 may be provided to close the expansion valve 116 (e.g., to close a solenoid valve of the expansion valve 116). At step 308, the controller 154 causes the compressor 106 to operate until a threshold low-side pressure 170 is achieved at the inlet of the compressor 106. For example, the compressor 106 may operate until the low-side pressure 170 measured by sensor 138 meets a threshold value 166.

At step 310, the controller 154 causes the compressor 106 to stop operating and waits for a predefined amount of time (e.g., for the waiting time 204 of FIG. 2). If needed, the controller 154 may also adjust the check valve 114 after operation of the compressor 106 is stopped, such that the refrigerant from the high-pressure subsystem 104a cannot backflow through the compressor 106 into the low-pressure subsystem 104b.

At step 312, the controller 154 monitors the low-side pressure 170 (e.g., as illustrated in FIG. 2) for at least a period of time (e.g., the monitoring time 206 of FIG. 2). At step 314, the controller 154 determines the rate of change 172 of the low-side pressure over the period of time. For example, referring to FIG. 2, the rate of change 172 may be determined as the change in pressure 208 over the monitoring time 206.

At step 316, the controller 154 determines if the rate of change 172 is negative and if a magnitude of the rate of change 172 is greater than a threshold value 166. If this is the case, the controller 154 proceeds to step 318 and determines that the refrigerant leak is in the low-pressure subsystem 104b of the HVAC system 100. Otherwise, if one or both of the rate of change 172 is not negative or the magnitude of the rate of change 172 is not greater than the threshold value 166, the controller 154 proceeds to step 320 and determines that the leak location 184 of the refrigerant may be in the high-pressure subsystem 104a.

At step 322, the controller 154 determines if there are any other failed components 186. For example, the controller 154 may determine the blower status 178 from information provided by the blower 130. If the blower status 178 indicates the blower 130 is not operating as intended, the blower 130 may be included as a failed component 186 in the system diagnosis 182. Similarly, a blocked air filter 144 may be included as a failed component 186, as described with respect to FIG. 1 above.

At step 324, the controller 154 determines the system diagnosis 182 which includes the leak location 184 from step 318 or 320 and any failed components 186 from step 322. At step 326, the system diagnosis 182 and/or any related alert(s) 152 (e.g., indicating a refrigerant leak) are displayed on the thermostat 148 and/or provided to the service provider 188, as described above.

Modifications, additions, or omissions may be made to method 300 depicted in FIG. 3. Method 300 may include more, fewer, or other steps. For example, steps may be

## 13

performed in parallel or in any suitable order. While at times discussed as controller **154**, HVAC system **100**, or components thereof performing the steps, any suitable HVAC system or components of the HVAC system may perform one or more steps of the method **300**.

While several embodiments have been provided in the present disclosure, it should be understood that the disclosed systems and methods might be embodied in many other specific forms without departing from the spirit or scope of the present disclosure. The present examples are to be considered as illustrative and not restrictive, and the intention is not to be limited to the details given herein. For example, the various elements or components may be combined or integrated in another system or certain features may be omitted, or not implemented.

In addition, techniques, systems, subsystems, and methods described and illustrated in the various embodiments as discrete or separate may be combined or integrated with other systems, modules, techniques, or methods without departing from the scope of the present disclosure. Other items shown or discussed as coupled or directly coupled or communicating with each other may be indirectly coupled or communicating through some interface, device, or intermediate component whether electrically, mechanically, or otherwise. Other examples of changes, substitutions, and alterations are ascertainable by one skilled in the art and could be made without departing from the spirit and scope disclosed herein.

To aid the Patent Office, and any readers of any patent issued on this application in interpreting the claims appended hereto, applicants note that they do not intend any of the appended claims to invoke 35 U.S.C. § 112(f) as it exists on the date of filing hereof unless the words “means for” or “step for” are explicitly used in the particular claim.

What is claimed is:

**1.** A heating, ventilation, and air conditioning (HVAC) system, the HVAC system comprising:

a high-pressure subsystem comprising:

a condenser operable to receive refrigerant and transfer heat from the refrigerant to a flow of outdoor air, thereby generating a cooled refrigerant; and  
a controllable valve positioned in a refrigerant conduit connecting the condenser to an evaporator; and

a low-pressure subsystem comprising:

the evaporator operable to receive the cooled refrigerant and transfer heat from a flow of air to the cooled refrigerant;  
a compressor operable to compress the refrigerant; and  
a pressure sensor operable to measure a refrigerant pressure in the low-pressure subsystem; and

a controller comprising a processor configured to:

monitor the refrigerant pressure in the low-pressure subsystem of the HVAC system for a period of time after operation of the compressor is stopped with the controllable valve closed;  
determine a rate of change of the refrigerant pressure in the low-pressure subsystem for the period of time;  
determine whether a leak location of the refrigerant is in the low-pressure subsystem of the HVAC system or the high-pressure subsystem of the HVAC system based at least in part upon the rate of change of the refrigerant pressure in the low-pressure subsystem.

**2.** The HVAC system of claim **1**, wherein the HVAC system further comprises:

a first sensor positioned and configured to measure a saturation temperature of the refrigerant in the evaporator; and

## 14

a second sensor positioned and configured to measure a superheated vapor temperature of the refrigerant in the evaporator; and

the controller is further configured to detect a possible leak of the refrigerant by:

determining a superheat value based on a difference between the saturation temperature and the superheated vapor temperature; and  
determining that both the saturation temperature is less than a corresponding threshold value and the superheat value is greater than a corresponding threshold value.

**3.** The HVAC system of claim **1**, wherein the processor is further configured to:

determine a system diagnosis comprising the leak location; and  
cause the system diagnosis to be provided to a service provider associated with the HVAC system.

**4.** The HVAC system of claim **1**, wherein the processor is further configured to:

determine a system diagnosis comprising the leak location; and  
cause the system diagnosis to be displayed on a thermostat associated with the HVAC system.

**5.** The HVAC system of claim **1**, wherein the processor is further configured to cause display of a mode indication on a thermostat of the HVAC system indicating that the HVAC system is operating in a diagnostic mode.

**6.** The HVAC system of claim **1**, further comprising:  
a blower operable, when functioning as intended, to provide the flow of air across the evaporator;  
wherein the controller is further communicatively coupled to the blower and configured to:  
determine a blower status indicating whether the blower is operating as intended; and  
determine a system diagnosis comprising the leak location and the blower status.

**7.** The HVAC system of claim **1**, further comprising:  
an air filter positioned and configured to filter the flow of air before the flow of air reaches the evaporator;  
an air filter sensor operable to measure a change in air pressure across the air filter;  
wherein the controller is further communicatively coupled to the filter sensor and configured to:  
detect a blockage of the air filter based on the change in air pressure across the air filter; and  
determine a system diagnosis comprising the leak location and an indication of the detected blockage of the air filter.

**8.** The HVAC system of claim **1**, wherein the HVAC system further comprises a check valve positioned proximate an output of the compressor and configured to prevent the refrigerant from flowing into the outlet of the compressor after operation of the compressor is stopped.

**9.** A method of operating a heating, ventilation, and air conditioning (HVAC) system, the method comprising:

monitoring a refrigerant pressure in a low-pressure subsystem of the HVAC system for a period of time after operation of a compressor is stopped with a controllable valve closed, wherein the controllable valve is positioned in a refrigerant conduit connecting a condenser to an evaporator;  
determining a rate of change of the refrigerant pressure in the low-pressure subsystem for the period of time; and  
determining whether a leak location of the refrigerant is in the low-pressure subsystem of the HVAC system or a high-pressure subsystem of the HVAC system based at

## 15

least in part upon the rate of change of the refrigerant pressure in the low-pressure subsystem.

- 10.** The method of claim **9**, further comprising detecting a possible leak of refrigerant from the HVAC system by:
- receiving a saturation temperature determined by a first sensor positioned and configured to measure the saturation temperature of the refrigerant in the evaporator;
  - receiving a superheated vapor temperature determined by a second sensor positioned and configured to measure the superheated vapor temperature of the refrigerant in the evaporator;
  - determining a superheat value based on a difference between the saturation temperature and the superheated vapor temperature; and
  - determining that both the saturation temperature is less than a corresponding threshold value and the superheat value is greater than a corresponding threshold value.
- 11.** The method of claim **9**, further comprising:
- determining a system diagnosis comprising the leak location; and
  - causing the system diagnosis to be provided to a service provider associated with the HVAC system.
- 12.** The method of claim **9**, further comprising:
- determining a system diagnosis comprising the leak location; and
  - causing the system diagnosis to be displayed on a thermostat associated with the HVAC system.
- 13.** The method of claim **9**, further comprising causing display of a mode indication on a thermostat of the HVAC system indicating that the HVAC system is operating in a diagnostic mode.
- 14.** The method of claim **9**, further comprising:
- determining a blower status indicating whether a blower of the HVAC system is operating as intended; and
  - determining a system diagnosis comprising the leak location and the blower status.
- 15.** The method of claim **9**, further comprising:
- detecting a blockage of an air filter of the HVAC system based on a change in air pressure across the air filter; and
  - determining a system diagnosis comprising the leak location and an indication of the detected blockage of the air filter.
- 16.** A controller of a heating, ventilation, and air conditioning (HVAC) system, the controller comprising:
- an input/output interface configured to communicate with:
    - a compressor of the HVAC system;
    - a controllable valve positioned in a refrigerant conduit connecting a condenser of the HVAC system to an evaporator of the HVAC system; and

## 16

a pressure sensor operable to measure a refrigerant pressure in a low-pressure subsystem of the HVAC system; and

- a processor communicatively coupled to the input/output interface and configured to:
    - monitor the refrigerant pressure in the low-pressure subsystem of the HVAC system for a period of time;
    - determine a rate of change of the refrigerant pressure in the low-pressure subsystem for the period of time; and
    - determine whether a leak location of the refrigerant is in the low-pressure subsystem of the HVAC system or a high-pressure subsystem of the HVAC system based at least in part upon the rate of change of the refrigerant pressure in the low-pressure subsystem.
- 17.** The controller of claim **16**, wherein the processor is further configured to detect a possible leak of the refrigerant by:
- determining a superheat value based on a difference between a saturation temperature of refrigerant in the evaporator and a superheated vapor temperature of refrigerant in the evaporator; and
  - determining that both the saturation temperature is less than a corresponding threshold value and the superheat value is greater than a corresponding threshold value.
- 18.** The controller of claim **16**, wherein the processor is further configured to:
- determine a system diagnosis comprising the leak location; and
  - cause the system diagnosis to be provided to a service provider associated with the HVAC system.
- 19.** The controller of claim **16**, wherein the processor is further configured to cause display of a mode indication on a thermostat of the HVAC system indicating that the HVAC system is operating in a diagnostic mode.
- 20.** The controller of claim **16**, wherein:
- the input/output interface is further configured to communicate with an air filter sensor operable to measure a change in air pressure across an air filter positioned and configured to filter a flow of air before the flow of air reaches the evaporator; and
  - the processor is further configured to:
    - detect a blockage of the air filter based on the change in air pressure across the air filter; and
    - determine a system diagnosis comprising the leak location and an indication of the detected blockage of the air filter.
