(57) **ABSTRACT**
A method and a device for transmitting or receiving information related to an access point in a wireless LAN system are disclosed. A method for receiving information related to one or more access points (APs) by a station (STA) in a wireless LAN system according to an embodiment of the present disclosure may comprise the steps of: transmitting a request frame including information indicating one or more of a first AP and a first multi-link device (MLD); and receiving a response frame responding to the request frame from a second AP, wherein the response frame includes a first multi-link (ML) element related to one or more of the first AP and the first MLD, and a second ML element related to one or more of the second AP and a second MLD.

METHOD AND DEVICE FOR TRANSMITTING OR RECEIVING ACCESS POINT-RELATED INFORMATION IN WIRELESS LAN SYSTEM

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a continuation of International Application No. PCT/KR2022/095123, filed on Sep. 13, 2022, which claims the benefit of earlier filing date and right of priority to Korean Application No. 10-2021-0122011, filed on Sep. 13, 2021, the contents of which are all hereby incorporated by reference herein in their entireties.

TECHNICAL FIELD

The present disclosure relates to a random access operation in a wireless local area network (WLAN) system, and more particularly, relates to a method and a device for transmitting or receiving information related to an access point.

BACKGROUND

New technologies for improving transmission rates, increasing bandwidth, improving reliability, reducing errors, and reducing latency have been introduced for a wireless LAN (WLAN). Among WLAN technologies, an Institute of Electrical and Electronics Engineers (IEEE) 802.11 series standard may be referred to as Wi-Fi. For example, technologies recently introduced to WLAN include enhancements for Very High-Throughput (VHT) of the 802.11ac standard, and enhancements for High Efficiency (HE) of the IEEE 802.11ax standard.

In order to provide a more improved wireless communication environment, an enhancement technologies for EHT (Extremely High Throughput) are being discussed. For example, technologies for multiple access point (AP) coordination and multiple input multiple output (MIMO) supporting an increased bandwidth, efficient utilization of multiple bands and increased spatial streams are being studied, and, in particular, various technologies for supporting low latency or real-time traffic are being studied.

SUMMARY

A technical problem of the present disclosure is to provide a method and a device for transmitting or receiving information related to an access point in a multi-link operation of a WLAN system.

An additional technical problem of the present disclosure is to provide a method and a device for transmitting or receiving information related to an access point in a multi-link operation supporting a multiple basic service set (BSS) identification information (multiple BSSID) set of a WLAN system.

An additional technical problem of the present disclosure is to provide a method and a device for transmitting or receiving information related to an access point supporting a multiple BSSID set and a multi-link operation as a response to a request from a non-access point station in a WLAN system.

The technical objects to be achieved by the present disclosure are not limited to the above-described technical objects, and other technical objects which are not described

2

herein will be clearly understood by those skilled in the pertinent art from the following description.

A method for receiving information related to at least one access point (AP) by a station (STA) in a wireless local area network (WLAN) system according to an aspect of the present disclosure includes transmitting a request frame including information indicating at least one of a first AP or a first multi-link device (MLD); and receiving a response frame responding to the request frame from a second AP, wherein the response frame may include a first multi-link (ML) element related to at least one of the first AP and the first MLD, and a second ML element related to at least one of the second AP and a second MLD.

A method for transmitting information related to at least one AP by a second access point (AP) in a WLAN system according to an additional aspect of the present disclosure includes receiving from a station (STA) a request frame including information indicating at least one of a first AP or a first multi-link device (MLD); and transmitting to the STA a response frame responding to the request frame, wherein the response frame may include a first multi-link (ML) element related to at least one of the first AP and the first MLD, and a second ML element related to at least one of the second AP and a second MLD.

According to the present disclosure, a method and a device for transmitting or receiving information related to an access point in a multi-link operation of a WLAN system may be provided.

According to the present disclosure, a method and a device for transmitting or receiving information related to an access point in a multi-link operation supporting a multiple basic service set (BSS) identification information (multiple BSSID) set of a WLAN system may be provided.

According to the present disclosure, a method and a device for transmitting or receiving information related to an access point supporting a multiple BSSID set and a multi-link operation as a response to a request from a non-access point station in a WLAN system may be provided.

Effects achievable by the present disclosure are not limited to the above-described effects, and other effects which are not described herein may be clearly understood by those skilled in the pertinent art from the following description.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are included as part of the detailed description to aid understanding of the present disclosure, provide embodiments of the present disclosure and together with the detailed description describe technical features of the present disclosure.

FIG. 1 illustrates a block configuration diagram of a wireless communication device according to an embodiment of the present disclosure.

FIG. 2 is a diagram illustrating an exemplary structure of a WLAN system to which the present disclosure may be applied.

FIG. 3 is a diagram for explaining a link setup process to which the present disclosure may be applied.

FIG. 4 is a diagram for explaining a backoff process to which the present disclosure may be applied.

FIG. 5 is a diagram for explaining a frame transmission operation based on CSMA/CA to which the present disclosure may be applied.

FIG. 6 is a diagram for explaining an example of a frame structure used in a WLAN system to which the present disclosure may be applied.

FIG. 7 is a diagram illustrating examples of PPDU's defined in the IEEE 802.11 standard to which the present disclosure may be applied.

FIGS. 8 to 10 are diagrams for explaining examples of resource units of a WLAN system to which the present disclosure may be applied.

FIG. 11 illustrates an example structure of a HE-SIG-B field.

FIG. 12 is a diagram for explaining a MU-MIMO method in which a plurality of users/STAs are allocated to one RU.

FIG. 13 illustrates an example of a PPDU format to which the present disclosure may be applied.

FIG. 14 exemplarily shows a structure of a ML element to which the present disclosure may be applied.

FIG. 15 is a diagram showing an exemplary relationship between a multiple BSSID set and a multi-link device to which the present disclosure may be applied.

FIG. 16 is a diagram for describing an example of a ML element of a MBSSID element to which the present disclosure may be applied.

FIG. 17 is a diagram for describing a method of receiving AP-related information according to the present disclosure.

FIG. 18 is a diagram for describing a method of transmitting AP-related information according to the present disclosure.

FIGS. 19 to 21 are a diagram showing a variety of examples of an AP-related information request and response process according to the present disclosure.

DETAILED DESCRIPTION

Hereinafter, embodiments according to the present disclosure will be described in detail by referring to accompanying drawings. Detailed description to be disclosed with accompanying drawings is to describe exemplary embodiments of the present disclosure and is not to represent the only embodiment that the present disclosure may be implemented. The following detailed description includes specific details to provide complete understanding of the present disclosure. However, those skilled in the pertinent art knows that the present disclosure may be implemented without such specific details.

In some cases, known structures and devices may be omitted or may be shown in a form of a block diagram based on a core function of each structure and device in order to prevent a concept of the present disclosure from being ambiguous.

In the present disclosure, when an element is referred to as being "connected", "combined" or "linked" to another element, it may include an indirect connection relation that yet another element presents therebetween as well as a direct connection relation. In addition, in the present disclosure, a term, "include" or "have", specifies the presence of a mentioned feature, step, operation, component and/or element, but it does not exclude the presence or addition of one or more other features, stages, operations, components, elements and/or their groups.

In the present disclosure, a term such as "first", "second", etc. is used only to distinguish one element from other element and is not used to limit elements, and unless otherwise specified, it does not limit an order or importance, etc. between elements. Accordingly, within a scope of the present disclosure, a first element in an embodiment may be referred to as a second element in another embodiment and likewise, a second element in an embodiment may be referred to as a first element in another embodiment.

A term used in the present disclosure is to describe a specific embodiment, and is not to limit a claim. As used in a described and attached claim of an embodiment, a singular form is intended to include a plural form, unless the context clearly indicates otherwise. A term used in the present disclosure, "and/or", may refer to one of related enumerated items or it means that it refers to and includes any and all possible combinations of two or more of them. In addition, "/" between words in the present disclosure has the same meaning as "and/or", unless otherwise described.

Examples of the present disclosure may be applied to various wireless communication systems. For example, examples of the present disclosure may be applied to a wireless LAN system. For example, examples of the present disclosure may be applied to an IEEE 802.11a/g/n/ac/ax standards-based wireless LAN. Furthermore, examples of the present disclosure may be applied to a wireless LAN based on the newly proposed IEEE 802.11be (or EHT) standard. Examples of the present disclosure may be applied to an IEEE 802.11be Release-2 standard-based wireless LAN corresponding to an additional enhancement technology of the IEEE 802.11be Release-1 standard. Additionally, examples of the present disclosure may be applied to a next-generation standards-based wireless LAN after IEEE 802.11be. Further, examples of this disclosure may be applied to a cellular wireless communication system. For example, it may be applied to a cellular wireless communication system based on Long Term Evolution (LTE)-based technology and 5G New Radio (NR)-based technology of the 3rd Generation Partnership Project (3GPP) standard.

Hereinafter, technical features to which examples of the present disclosure may be applied will be described.

FIG. 1 illustrates a block diagram of a wireless communication device according to an embodiment of the present disclosure.

The first device 100 and the second device 200 illustrated in FIG. 1 may be replaced with various terms such as a terminal, a wireless device, a Wireless Transmit Receive Unit (WTRU), an User Equipment (UE), a Mobile Station (MS), an user terminal (UT), a Mobile Subscriber Station (MSS), a Mobile Subscriber Unit (MSU), a subscriber station (SS), an advanced mobile station (AMS), a wireless terminal (WT), or simply user, etc. In addition, the first device 100 and the second device 200 include an access point (AP), a base station (BS), a fixed station, a Node B, a base transceiver system (BTS), a network, It may be replaced with various terms such as an Artificial Intelligence (AI) system, a road side unit (RSU), a repeater, a router, a relay, and a gateway.

The devices 100 and 200 illustrated in FIG. 1 may be referred to as stations (STAs). For example, the devices 100 and 200 illustrated in FIG. 1 may be referred to by various terms such as a transmitting device, a receiving device, a transmitting STA, and a receiving STA. For example, the STAs 110 and 200 may perform an access point (AP) role or a non-AP role. That is, in the present disclosure, the STAs 110 and 200 may perform functions of an AP and/or a non-AP. When the STAs 110 and 200 perform an AP function, they may be simply referred to as APs, and when the STAs 110 and 200 perform non-AP functions, they may be simply referred to as STAs. In addition, in the present disclosure, an AP may also be indicated as an AP STA.

Referring to FIG. 1, the first device 100 and the second device 200 may transmit and receive radio signals through various wireless LAN technologies (e.g., IEEE 802.11 series). The first device 100 and the second device 200 may

5

include an interface for a medium access control (MAC) layer and a physical layer (PHY) conforming to the IEEE 802.11 standard.

In addition, the first device **100** and the second device **200** may additionally support various communication standards (e.g., 3GPP LTE series, 5G NR series standards, etc.) technologies other than wireless LAN technology. In addition, the device of the present disclosure may be implemented in various devices such as a mobile phone, a vehicle, a personal computer, augmented reality (AR) equipment, and virtual reality (VR) equipment, etc. In addition, the STA of the present specification may support various communication services such as a voice call, a video call, data communication, autonomous-driving, machine-type communication (MTC), machine-to-machine (M2M), device-to-device (D2D), IoT (Internet-of-Things), etc.

A first device **100** may include one or more processors **102** and one or more memories **104** and may additionally include one or more transceivers **106** and/or one or more antennas **108**. A processor **102** may control a memory **104** and/or a transceiver **106** and may be configured to implement description, functions, procedures, proposals, methods and/or operation flow charts disclosed in the present disclosure. For example, a processor **102** may transmit a wireless signal including first information/signal through a transceiver **106** after generating first information/signal by processing information in a memory **104**. In addition, a processor **102** may receive a wireless signal including second information/signal through a transceiver **106** and then store information obtained by signal processing of second information/signal in a memory **104**. A memory **104** may be connected to a processor **102** and may store a variety of information related to an operation of a processor **102**. For example, a memory **104** may store a software code including instructions for performing all or part of processes controlled by a processor **102** or for performing description, functions, procedures, proposals, methods and/or operation flow charts disclosed in the present disclosure. Here, a processor **102** and a memory **104** may be part of a communication modem/circuit/chip designed to implement a wireless LAN technology (e.g., IEEE 802.11 series). A transceiver **106** may be connected to a processor **102** and may transmit and/or receive a wireless signal through one or more antennas **108**. A transceiver **106** may include a transmitter and/or a receiver. A transceiver **106** may be used together with a RF (Radio Frequency) unit. In the present disclosure, a device may mean a communication modem/circuit/chip.

A second device **200** may include one or more processors **202** and one or more memories **204** and may additionally include one or more transceivers **206** and/or one or more antennas **208**. A processor **202** may control a memory **204** and/or a transceiver **206** and may be configured to implement description, functions, procedures, proposals, methods and/or operation flows charts disclosed in the present disclosure. For example, a processor **202** may generate third information/signal by processing information in a memory **204**, and then transmit a wireless signal including third information/signal through a transceiver **206**. In addition, a processor **202** may receive a wireless signal including fourth information/signal through a transceiver **206**, and then store information obtained by signal processing of fourth information/signal in a memory **204**. A memory **204** may be connected to a processor **202** and may store a variety of information related to an operation of a processor **202**. For example, a memory **204** may store a software code including instructions for performing all or part of processes con-

6

trolled by a processor **202** or for performing description, functions, procedures, proposals, methods and/or operation flow charts disclosed in the present disclosure. Here, a processor **202** and a memory **204** may be part of a communication modem/circuit/chip designed to implement a wireless LAN technology (e.g., IEEE 802.11 series). A transceiver **206** may be connected to a processor **202** and may transmit and/or receive a wireless signal through one or more antennas **208**. A transceiver **206** may include a transmitter and/or a receiver. A transceiver **206** may be used together with a RF unit. In the present disclosure, a device may mean a communication modem/circuit/chip.

Hereinafter, a hardware element of a device **100**, **200** will be described in more detail. It is not limited thereto, but one or more protocol layers may be implemented by one or more processors **102**, **202**. For example, one or more processors **102**, **202** may implement one or more layers (e.g., a functional layer such as PHY, MAC). One or more processors **102**, **202** may generate one or more PDUs (Protocol Data Unit) and/or one or more SDUs (Service Data Unit) according to description, functions, procedures, proposals, methods and/or operation flow charts disclosed in the present disclosure. One or more processors **102**, **202** may generate a message, control information, data or information according to description, functions, procedures, proposals, methods and/or operation flow charts disclosed in the present disclosure. One or more processors **102**, **202** may generate a signal (e.g., a baseband signal) including a PDU, a SDU, a message, control information, data or information according to functions, procedures, proposals and/or methods disclosed in the present disclosure to provide it to one or more transceivers **106**, **206**. One or more processors **102**, **202** may receive a signal (e.g., a baseband signal) from one or more transceivers **106**, **206** and obtain a PDU, a SDU, a message, control information, data or information according to description, functions, procedures, proposals, methods and/or operation flow charts disclosed in the present disclosure.

One or more processors **102**, **202** may be referred to as a controller, a micro controller, a micro processor or a micro computer. One or more processors **102**, **202** may be implemented by a hardware, a firmware, a software, or their combination. In an example, one or more ASICs (Application Specific Integrated Circuit), one or more DSPs (Digital Signal Processor), one or more DSPDs (Digital Signal Processing Device), one or more PLDs (Programmable Logic Device) or one or more FPGAs (Field Programmable Gate Arrays) may be included in one or more processors **102**, **202**. Description, functions, procedures, proposals, methods and/or operation flow charts disclosed in the present disclosure may be implemented by using a firmware or a software and a firmware or a software may be implemented to include a module, a procedure, a function, etc. A firmware or a software configured to perform description, functions, procedures, proposals, methods and/or operation flow charts disclosed in the present disclosure may be included in one or more processors **102**, **202** or may be stored in one or more memories **104**, **204** and driven by one or more processors **102**, **202**. Description, functions, procedures, proposals, methods and/or operation flow charts disclosed in the present disclosure may be implemented by using a firmware or a software in a form of a code, an instruction and/or a set of instructions.

One or more memories **104**, **204** may be connected to one or more processors **102**, **202** and may store data, a signal, a message, information, a program, a code, an indication and/or an instruction in various forms. One or more memo-

ries **104, 204** may be configured with ROM, RAM, EPROM, a flash memory, a hard drive, a register, a cash memory, a computer readable storage medium and/or their combination. One or more memories **104, 204** may be positioned inside and/or outside one or more processors **102, 202**. In addition, one or more memories **104, 204** may be connected to one or more processors **102, 202** through a variety of technologies such as a wire or wireless connection.

One or more transceivers **106, 206** may transmit user data, control information, a wireless signal/channel, etc. mentioned in methods and/or operation flow charts, etc. of the present disclosure to one or more other devices. One or more transceivers **106, 206** may receive user data, control information, a wireless signal/channel, etc. mentioned in description, functions, procedures, proposals, methods and/or operation flow charts, etc. disclosed in the present disclosure from one or more other devices. For example, one or more transceivers **106, 206** may be connected to one or more processors **102, 202** and may transmit and receive a wireless signal. For example, one or more processors **102, 202** may control one or more transceivers **106, 206** to transmit user data, control information or a wireless signal to one or more other devices. In addition, one or more processors **102, 202** may control one or more transceivers **106, 206** to receive user data, control information or a wireless signal from one or more other devices. In addition, one or more transceivers **106, 206** may be connected to one or more antennas **108, 208** and one or more transceivers **106, 206** may be configured to transmit and receive user data, control information, a wireless signal/channel, etc. mentioned in description, functions, procedures, proposals, methods and/or operation flow charts, etc. disclosed in the present disclosure through one or more antennas **108, 208**. In the present disclosure, one or more antennas may be a plurality of physical antennas or a plurality of logical antennas (e.g., an antenna port). One or more transceivers **106, 206** may convert a received wireless signal/channel, etc. into a baseband signal from a RF band signal to process received user data, control information, wireless signal/channel, etc. by using one or more processors **102, 202**. One or more transceivers **106, 206** may convert user data, control information, a wireless signal/channel, etc. which are processed by using one or more processors **102, 202** from a baseband signal to a RF band signal. Therefore, one or more transceivers **106, 206** may include an (analogue) oscillator and/or a filter.

For example, one of the STAs **100** and **200** may perform an intended operation of an AP, and the other of the STAs **100** and **200** may perform an intended operation of a non-AP STA. For example, the transceivers **106** and **206** of FIG. 1 may perform a transmission and reception operation of a signal (e.g., a packet or a physical layer protocol data unit (PPDU) conforming to IEEE 802.11a/b/g/n/ac/ax/be). In addition, in the present disclosure, an operation in which various STAs generate transmission/reception signals or perform data processing or calculation in advance for transmission/reception signals may be performed by the processors **102** and **202** of FIG. 1. For example, an example of an operation of generating a transmission/reception signal or performing data processing or calculation in advance for the transmission/reception signal may include 1) Determining/acquiring/configuring/calculating/decoding/encoding bit information of fields (signal (SIG), short training field (STF), long training field (LTF), Data, etc.) included in the PPDU, 2) Determining/configuring/acquiring time resources or frequency resources (e.g., subcarrier resources) used for fields (SIG, STF, LTF, Data, etc.) included in the PPDU; 3) Determining/configuring/acquiring a specific sequence (e.g.,

pilot sequence, STF/LTF sequence, extra sequence applied to SIG) used for fields (SIG, STF, LTF, Data, etc.) included in the PPDU action, 4) power control operation and/or power saving operation applied to the STA, 5) Operations related to ACK signal determination/acquisition/configuration/calculation/decoding/encoding, etc. In addition, in the following example, various information (e.g., information related to fields/subfields/control fields/parameters/power, etc.) used by various STAs to determine/acquire/configure/calculate/decode/encode transmission and reception signals may be stored in the memories **104** and **204** of FIG. 1.

Hereinafter, downlink (DL) may mean a link for communication from an AP STA to a non-AP STA, and a DL PPDU/packet/signal may be transmitted and received through the DL. In DL communication, a transmitter may be part of an AP STA, and a receiver may be part of a non-AP STA. Uplink (UL) may mean a link for communication from non-AP STAs to AP STAs, and a UL PPDU/packet/signal may be transmitted and received through the UL. In UL communication, a transmitter may be part of a non-AP STA, and a receiver may be part of an AP STA.

FIG. 2 is a diagram illustrating an exemplary structure of a wireless LAN system to which the present disclosure may be applied.

The structure of the wireless LAN system may consist of be composed of a plurality of components. A wireless LAN supporting STA mobility transparent to an upper layer may be provided by interaction of a plurality of components. A Basic Service Set (BSS) corresponds to a basic construction block of a wireless LAN. FIG. 2 exemplarily shows that two BSSs (BSS1 and BSS2) exist and two STAs are included as members of each BSS (STA1 and STA2 are included in BSS1, and STA3 and STA4 are included in BSS2). An ellipse representing a BSS in FIG. 2 may also be understood as representing a coverage area in which STAs included in the corresponding BSS maintain communication. This area may be referred to as a Basic Service Area (BSA). When an STA moves out of the BSA, it may not directly communicate with other STAs within the BSA.

If the DS shown in FIG. 2 is not considered, the most basic type of BSS in a wireless LAN is an independent BSS (IBSS). For example, IBSS may have a minimal form containing only two STAs. For example, assuming that other components are omitted, BSS1 containing only STA1 and STA2 or BSS2 containing only STA3 and STA4 may respectively correspond to representative examples of IBSS. This configuration is possible when STAs may communicate directly without an AP. In addition, in this type of wireless LAN, it is not configured in advance, but may be configured when a LAN is required, and this may be referred to as an ad-hoc network. Since the IBSS does not include an AP, there is no centralized management entity. That is, in IBSS, STAs are managed in a distributed manner. In IBSS, all STAs may be made up of mobile STAs, and access to the distributed system (DS) is not allowed, forming a self-contained network.

Membership of an STA in the BSS may be dynamically changed by turning on or off the STA, entering or exiting the BSS area, and the like. To become a member of the BSS, the STA may join the BSS using a synchronization process. In order to access all services of the BSS infrastructure, the STA shall be associated with the BSS. This association may be dynamically established and may include the use of a Distribution System Service (DSS).

A direct STA-to-STA distance in a wireless LAN may be limited by PHY performance. In some cases, this distance limit may be sufficient, but in some cases, communication

between STAs at a longer distance may be required. A distributed system (DS) may be configured to support extended coverage.

DS means a structure in which BSSs are interconnected. Specifically, as shown in FIG. 2, a BSS may exist as an extended form of a network composed of a plurality of BSSs. DS is a logical concept and may be specified by the characteristics of Distributed System Media (DSM). In this regard, a wireless medium (WM) and a DSM may be logically separated. Each logical medium is used for a different purpose and is used by different components. These medium are not limited to being the same, nor are they limited to being different. In this way, the flexibility of the wireless LAN structure (DS structure or other network structure) may be explained in that a plurality of media are logically different. That is, the wireless LAN structure may be implemented in various ways, and the corresponding wireless LAN structure may be independently specified by the physical characteristics of each embodiment.

A DS may support a mobile device by providing seamless integration of a plurality of BSSs and providing logical services necessary to address an address to a destination. In addition, the DS may further include a component called a portal that serves as a bridge for connection between the wireless LAN and other networks (e.g., IEEE 802.X).

The AP enables access to the DS through the WM for the associated non-AP STAs, and means an entity that also has the functionality of an STA. Data movement between the BSS and the DS may be performed through the AP. For example, STA2 and STA3 shown in FIG. 2 have the functionality of STAs, and provide a function allowing the associated non-AP STAs (STA1 and STA4) to access the DS. In addition, since all APs basically correspond to STAs, all APs are addressable entities. The address used by the AP for communication on the WM and the address used by the AP for communication on the DSM are not necessarily the same. A BSS composed of an AP and one or more STAs may be referred to as an infrastructure BSS.

Data transmitted from one of the STA(s) associated with an AP to a STA address of the corresponding AP may be always received on an uncontrolled port and may be processed by an IEEE 802.1X port access entity. In addition, when a controlled port is authenticated, transmission data (or frames) may be delivered to the DS.

In addition to the structure of the DS described above, an extended service set (ESS) may be configured to provide wide coverage.

An ESS means a network in which a network having an arbitrary size and complexity is composed of DSs and BSSs. The ESS may correspond to a set of BSSs connected to one DS. However, the ESS does not include the DS. An ESS network is characterized by being seen as an IBSS in the Logical Link Control (LLC) layer. STAs included in the ESS may communicate with each other, and mobile STAs may move from one BSS to another BSS (within the same ESS) transparently to the LLC. APs included in one ESS may have the same service set identification (SSID). The SSID is distinguished from the BSSID, which is an identifier of the BSS.

The wireless LAN system does not assume anything about the relative physical locations of BSSs, and all of the following forms are possible. BSSs may partially overlap, which is a form commonly used to provide continuous coverage. In addition, BSSs may not be physically connected, and logically there is no limit on the distance between BSSs. In addition, the BSSs may be physically located in the same location, which may be used to provide

redundancy. In addition, one (or more than one) IBSS or ESS networks may physically exist in the same space as one (or more than one) ESS network. When an ad-hoc network operates in a location where an ESS network exists, when physically overlapping wireless networks are configured by different organizations, or when two or more different access and security policies are required in the same location, this may correspond to the form of an ESS network in the like.

FIG. 3 is a diagram for explaining a link setup process to which the present disclosure may be applied.

In order for an STA to set up a link with respect to a network and transmit/receive data, it first discovers a network, performs authentication, establishes an association, and need to perform the authentication process for security. The link setup process may also be referred to as a session initiation process or a session setup process. In addition, the processes of discovery, authentication, association, and security setting of the link setup process may be collectively referred to as an association process.

In step S310, the STA may perform a network discovery operation. The network discovery operation may include a scanning operation of the STA. That is, in order for the STA to access the network, it needs to find a network in which it can participate. The STA shall identify a compatible network before participating in a wireless network, and the process of identifying a network existing in a specific area is called scanning.

Scanning schemes include active scanning and passive scanning. FIG. 3 exemplarily illustrates a network discovery operation including an active scanning process. In active scanning, an STA performing scanning transmits a probe request frame to discover which APs exist around it while moving channels and waits for a response thereto. A responder transmits a probe response frame as a response to the probe request frame to the STA that has transmitted the probe request frame. Here, the responder may be an STA that last transmitted a beacon frame in the BSS of the channel being scanned. In the BSS, since the AP transmits the beacon frame, the AP becomes a responder, and in the IBSS, the STAs in the IBSS rotate to transmit the beacon frame, so the responder is not constant. For example, a STA that transmits a probe request frame on channel 1 and receives a probe response frame on channel 1, may store BSS-related information included in the received probe response frame and may move to the next channel (e.g., channel 2) and perform scanning (i.e., transmission/reception of a probe request/response on channel 2) in the same manner.

Although not shown in FIG. 3, the scanning operation may be performed in a passive scanning manner. In passive scanning, a STA performing scanning waits for a beacon frame while moving channels. The beacon frame is one of the management frames defined in IEEE 802.11, and is periodically transmitted to notify the existence of a wireless network and to allow the STA performing scanning to find a wireless network and participate in the wireless network. In the BSS, the AP serves to transmit beacon frames periodically, and in the IBSS, STAs within the IBSS rotate to transmit beacon frames. When the STA performing scanning receives a beacon frame, the STA stores information for the BSS included in the beacon frame and records beacon frame information in each channel while moving to another channel. The STA receiving the beacon frame may store BSS-related information included in the received beacon frame, move to the next channel, and perform scanning in the next channel in the same way. Comparing active scanning and

11

passive scanning, active scanning has an advantage of having less delay and less power consumption than passive scanning.

After the STA discovers the network, an authentication process may be performed in step S320. This authentication process may be referred to as a first authentication process in order to be clearly distinguished from the security setup operation of step S340 to be described later.

The authentication process includes a process in which the STA transmits an authentication request frame to the AP, and in response to this, the AP transmits an authentication response frame to the STA. An authentication frame used for authentication request/response corresponds to a management frame.

The authentication frame includes an authentication algorithm number, an authentication transaction sequence number, a status code, a challenge text, a robust security network (RSN), and a Finite Cyclic Group, etc. This corresponds to some examples of information that may be included in the authentication request/response frame, and may be replaced with other information or additional information may be further included.

The STA may transmit an authentication request frame to the AP. The AP may determine whether to allow authentication of the corresponding STA based on information included in the received authentication request frame. The AP may provide the result of the authentication process to the STA through an authentication response frame.

After the STA is successfully authenticated, an association process may be performed in step S330. The association process includes a process in which the STA transmits an association request frame to the AP, and in response, the AP transmits an association response frame to the STA.

For example, the association request frame may include information related to various capabilities, a beacon listen interval, a service set identifier (SSID), supported rates, supported channels, RSN, mobility domain, supported operating classes, Traffic Indication Map Broadcast request (TIM broadcast request), interworking service capability, etc. For example, the association response frame may include information related to various capabilities, status code, association ID (AID), supported rates, enhanced distributed channel access (EDCA) parameter set, received channel power indicator (RCPI), received signal to noise indicator (RSNI), mobility domain, timeout interval (e.g., association comeback time), overlapping BSS scan parameters, TIM broadcast response, Quality of Service (QoS) map, etc. This corresponds to some examples of information that may be included in the association request/response frame, and may be replaced with other information or additional information may be further included.

After the STA is successfully associated with the network, a security setup process may be performed in step S340. The security setup process of step S340 may be referred to as an authentication process through Robust Security Network Association (RSNA) request/response, and the authentication process of step S320 is referred to as a first authentication process, and the security setup process of step S340 may also simply be referred to as an authentication process.

The security setup process of step S340 may include, for example, a process of setting up a private key through 4-way handshaking through an Extensible Authentication Protocol over LAN (EAPOL) frame. In addition, the security setup process may be performed according to a security scheme not defined in the IEEE 802.11 standard.

FIG. 4 is a diagram for explaining a backoff process to which the present disclosure may be applied.

12

In the wireless LAN system, a basic access mechanism of medium access control (MAC) is a carrier sense multiple access with collision avoidance (CSMA/CA) mechanism. The CSMA/CA mechanism is also called Distributed Coordination Function (DCF) of IEEE 802.11 MAC, and basically adopts a “listen before talk” access mechanism. According to this type of access mechanism, the AP and/or STA may perform Clear Channel Assessment (CCA) sensing a radio channel or medium during a predetermined time interval (e.g., DCF Inter-Frame Space (DIFS)), prior to starting transmission. As a result of the sensing, if it is determined that the medium is in an idle state, frame transmission is started through the corresponding medium. On the other hand, if it is detected that the medium is occupied or busy, the corresponding AP and/or STA does not start its own transmission and may set a delay period for medium access (e.g., a random backoff period) and attempt frame transmission after waiting. By applying the random backoff period, since it is expected that several STAs attempt frame transmission after waiting for different periods of time, collision may be minimized.

In addition, the IEEE 802.11 MAC protocol provides a Hybrid Coordination Function (HCF). HCF is based on the DCF and Point Coordination Function (PCF). PCF is a polling-based synchronous access method and refers to a method in which all receiving APs and/or STAs periodically poll to receive data frames. In addition, HCF has Enhanced Distributed Channel Access (EDCA) and HCF Controlled Channel Access (HCCA). EDCA is a contention-based access method for a provider to provide data frames to multiple users, and HCCA uses a non-contention-based channel access method using a polling mechanism. In addition, the HCF includes a medium access mechanism for improving QoS (Quality of Service) of the wireless LAN, and may transmit QoS data in both a Contention Period (CP) and a Contention Free Period (CFP).

Referring to FIG. 4, an operation based on a random backoff period will be described. When the occupied/busy medium changes to an idle state, several STAs may attempt to transmit data (or frames). As a method for minimizing collisions, each of STAs may respectively select a random backoff count and attempt transmission after waiting for a corresponding slot time. The random backoff count has a pseudo-random integer value and may be determined as one of values ranging from 0 to CW. Here, CW is a contention window parameter value. The CW parameter is given CWmin as an initial value, but may take a value twice as large in case of transmission failure (e.g., when an ACK for the transmitted frame is not received). When the CW parameter value reaches CWmax, data transmission may be attempted while maintaining the CWmax value until data transmission is successful, and when data transmission is successful, the CWmin value is reset. The values of CW, CWmin and CWmax are preferably set to $2n-1$ ($n=0, 1, 2, \dots$).

When the random backoff process starts, the STA continuously monitors the medium while counting down the backoff slots according to the determined backoff count value. When the medium is monitored for occupancy, it stops counting down and waits, and resumes the rest of the countdown when the medium becomes idle.

In the example of FIG. 4, when a packet to be transmitted arrives at the MAC of STA3, STA3 may transmit the frame immediately after confirming that the medium is idle as much as DIFS. The remaining STAs monitor and wait for the medium to be occupied/busy. In the meantime, data to be transmitted may also occur in each of STA1, STA2, and

STA5, and each STA waits as long as DIFS when the medium is monitored as idle, and then may perform a countdown of the backoff slot according to the random backoff count value selected by each STA. Assume that STA2 selects the smallest backoff count value and STA1 selects the largest backoff count value. That is, the case where the remaining back-off time of STA5 is shorter than the remaining back-off time of STA1 at the time when STA2 completes the back-off count and starts frame transmission is exemplified. STA1 and STA5 temporarily stop counting down and wait while STA2 occupies the medium. When the occupation of STA2 ends and the medium becomes idle again, STA1 and STA5 wait for DIFS and resume the stopped backoff count. That is, frame transmission may be started after counting down the remaining backoff slots for the remaining backoff time. Since the remaining backoff time of STA5 is shorter than that of STA1, STA5 starts frame transmission. While STA2 occupies the medium, data to be transmitted may also occur in STA4. From the standpoint of STA4, when the medium becomes idle, STA4 may wait for DIFS, and then may perform a countdown according to the random backoff count value selected by the STA4 and start transmitting frames. The example of FIG. 4 shows a case where the remaining backoff time of STA5 coincides with the random backoff count value of STA4 by chance. In this case, a collision may occur between STA4 and STA5. When a collision occurs, both STA4 and STA5 do not receive an ACK, so data transmission fails. In this case, STA4 and STA5 may double the CW value, select a random backoff count value, and perform a countdown. STA1 waits while the medium is occupied due to transmission of STA4 and STA5, waits for DIFS when the medium becomes idle, and then starts frame transmission after the remaining backoff time has elapsed.

As in the example of FIG. 4, the data frame is a frame used for transmission of data forwarded to a higher layer, and may be transmitted after a backoff performed after DIFS elapses from when the medium becomes idle. Additionally, the management frame is a frame used for exchange of management information that is not forwarded to a higher layer, and is transmitted after a backoff performed after an IFS such as DIFS or Point Coordination Function IFS (PIFS). As a subtype frames of management frame, there are a Beacon, an association request/response, a re-association request/response, a probe request/response, an authentication request/response, etc. A control frame is a frame used to control access to a medium. As a subtype frames of control frame, there are Request-To-Send (RTS), Clear-To-Send (CTS), Acknowledgement (ACK), Power Save-Poll (PS-Poll), block ACK (BlockAck), block ACK request (Block-ACKReq), null data packet announcement (NDP announcement), and trigger, etc. If the control frame is not a response frame of the previous frame, it is transmitted after backoff performed after DIFS elapses, and if it is a response frame of the previous frame, it is transmitted without performing backoff after short IFS (SIFS) elapses. The type and subtype of the frame may be identified by a type field and a subtype field in a frame control (FC) field.

A Quality of Service (QoS) STA may perform the backoff that is performed after an arbitration IFS (AIFS) for an access category (AC) to which the frame belongs, that is, AIFS[i] (where i is a value determined by AC), and then may transmit the frame. Here, the frame in which AIFS[i] can be used may be a data frame, a management frame, or a control frame other than a response frame.

FIG. 5 is a diagram for explaining a frame transmission operation based on CSMA/CA to which the present disclosure may be applied.

As described above, the CSMA/CA mechanism includes virtual carrier sensing in addition to physical carrier sensing in which a STA directly senses a medium. Virtual carrier sensing is intended to compensate for problems that may occur in medium access, such as a hidden node problem. For virtual carrier sensing, the MAC of the STA may use a Network Allocation Vector (NAV). The NAV is a value indicating, to other STAs, the remaining time until the medium is available for use by an STA currently using or having the right to use the medium. Therefore, the value set as NAV corresponds to a period in which the medium is scheduled to be used by the STA transmitting the frame, and the STA receiving the NAV value is prohibited from accessing the medium during the corresponding period. For example, the NAV may be configured based on the value of the "duration" field of the MAC header of the frame.

In the example of FIG. 5, it is assumed that a STA1 intends to transmit data to a STA2, and a STA3 is in a position capable of overhearing some or all of frames transmitted and received between the STA1 and the STA2.

In order to reduce the possibility of collision of transmissions of multiple STAs in CSMA/CA based frame transmission operation, a mechanism using RTS/CTS frames may be applied. In the example of FIG. 5, while transmission of the STA1 is being performed, as a result of carrier sensing of the STA3, it may be determined that the medium is in an idle state. That is, the STA1 may correspond to a hidden node to the STA3. Alternatively, in the example of FIG. 5, it may be determined that the carrier sensing result medium of the STA3 is in an idle state while transmission of the STA2 is being performed. That is, the STA2 may correspond to a hidden node to the STA3. Through the exchange of RTS/CTS frames before performing data transmission and reception between the STA1 and the STA2, a STA outside the transmission range of one of the STA1 or the STA2, or a STA outside the carrier sensing range for transmission from the STA1 or the STA3 may not attempt to occupy the channel during data transmission and reception between the STA1 and the STA2.

Specifically, the STA1 may determine whether a channel is being used through carrier sensing. In terms of physical carrier sensing, the STA1 may determine a channel occupation idle state based on an energy level or signal correlation detected in a channel. In addition, in terms of virtual carrier sensing, the STA1 may determine a channel occupancy state using a network allocation vector (NAV) timer.

The STA1 may transmit an RTS frame to the STA2 after performing a backoff when the channel is in an idle state during DIFS. When the STA2 receives the RTS frame, the STA2 may transmit a CTS frame as a response to the RTS frame to the STA1 after SIFS.

If the STA3 cannot overhear the CTS frame from the STA2 but can overhear the RTS frame from the STA1, the STA3 may set a NAV timer for a frame transmission period (e.g., SIFS+CTS frame+SIFS+data frame+SIFS+ACK frame) that is continuously transmitted thereafter, using the duration information included in the RTS frame. Alternatively, if the STA3 can overhear a CTS frame from the STA2 although the STA3 cannot overhear an RTS frame from the STA1, the STA3 may set a NAV timer for a frame transmission period (e.g., SIFS+data frame+SIFS+ACK frame) that is continuously transmitted thereafter, using the duration information included in the CTS frame. That is, if the STA3 can overhear one or more of the RTS or CTS frames from

15

one or more of the STA1 or the STA2, the STA3 may set the NAV accordingly. When the STA3 receives a new frame before the NAV timer expires, the STA3 may update the NAV timer using duration information included in the new frame. The STA3 does not attempt channel access until the NAV timer expires.

When the STA1 receives the CTS frame from the STA2, the STA1 may transmit the data frame to the STA2 after SIFS from the time point when the reception of the CTS frame is completed. When the STA2 successfully receives the data frame, the STA2 may transmit an ACK frame as a response to the data frame to the STA1 after SIFS. The STA3 may determine whether the channel is being used through carrier sensing when the NAV timer expires. When the STA3 determines that the channel is not used by other terminals during DIFS after expiration of the NAV timer, the STA3 may attempt channel access after a contention window (CW) according to a random backoff has passed.

FIG. 6 is a diagram for explaining an example of a frame structure used in a WLAN system to which the present disclosure may be applied.

By means of an instruction or primitive (meaning a set of instructions or parameters) from the MAC layer, the PHY layer may prepare a MAC PDU (MPDU) to be transmitted. For example, when a command requesting transmission start of the PHY layer is received from the MAC layer, the PHY layer switches to the transmission mode and configures information (e.g., data) provided from the MAC layer in the form of a frame and transmits it. In addition, when the PHY layer detects a valid preamble of the received frame, the PHY layer monitors the header of the preamble and sends a command notifying the start of reception of the PHY layer to the MAC layer.

In this way, information transmission/reception in a wireless LAN system is performed in the form of a frame, and for this purpose, a PHY layer protocol data unit (PPDU) frame format is defined.

A basic PPDU frame may include a Short Training Field (STF), a Long Training Field (LTF), a SIGNAL (SIG) field, and a Data field. The most basic (e.g., non-High Throughput (HT)) PPDU frame format may consist of only L-STF (Legacy-STF), L-LTF (Legacy-LTF), SIG field, and data field. In addition, depending on the type of PPDU frame format (e.g., HT-mixed format PPDU, HT-greenfield format PPDU, VHT (Very High Throughput) PPDU, etc.), an additional (or different type) STF, LTF, and SIG fields may be included between the SIG field and the data field (this will be described later with reference to FIG. 7).

The STF is a signal for signal detection, automatic gain control (AGC), diversity selection, precise time synchronization, and the like, and the LTF is a signal for channel estimation and frequency error estimation. The STF and LTF may be referred to as signals for synchronization and channel estimation of the OFDM physical layer.

The SIG field may include a RATE field and a LENGTH field. The RATE field may include information on modulation and coding rates of data. The LENGTH field may include information on the length of data. Additionally, the SIG field may include a parity bit, a SIG TAIL bit, and the like.

The data field may include a SERVICE field, a physical layer service data unit (PSDU), and a PPDU TAIL bit, and may also include padding bits if necessary. Some bits of the SERVICE field may be used for synchronization of the descrambler at the receiving end. The PSDU corresponds to the MAC PDU defined in the MAC layer, and may include data generated/used in the upper layer. The PPDU TAIL bit

16

may be used to return the encoder to a 0 state. Padding bits may be used to adjust the length of a data field in a predetermined unit.

A MAC PDU is defined according to various MAC frame formats, and a basic MAC frame consists of a MAC header, a frame body, and a Frame Check Sequence (FCS). The MAC frame may consist of MAC PDUs and be transmitted/received through the PSDU of the data part of the PPDU frame format.

The MAC header includes a Frame Control field, a Duration/ID field, an Address field, and the like. The frame control field may include control information required for frame transmission/reception. The duration/ID field may be set to a time for transmitting a corresponding frame or the like. For details of the Sequence Control, QoS Control, and HT Control subfields of the MAC header, refer to the IEEE 802.11 standard document.

A null-data packet (NDP) frame format means a frame format that does not include a data packet. That is, the NDP frame refers to a frame format that includes a physical layer convergence procedure (PLCP) header part (i.e., STF, LTF, and SIG fields) in a general PPDU frame format and does not include the remaining parts (i.e., data field). A NDP frame may also be referred to as a short frame format.

FIG. 7 is a diagram illustrating examples of PPDUs defined in the IEEE 802.11 standard to which the present disclosure may be applied.

In standards such as IEEE 802.11a/g/n/ac/ax, various types of PPDUs have been used. The basic PPDU format (IEEE 802.11a/g) includes L-LTF, L-STF, L-SIG and Data fields. The basic PPDU format may also be referred to as a non-HT PPDU format.

The HT PPDU format (IEEE 802.11n) additionally includes HT-SIG, HT-STF, and HT-LTF(s) fields to the basic PPDU format. The HT PPDU format shown in FIG. 7 may be referred to as an HT-mixed format. In addition, an HT-greenfield format PPDU may be defined, and this corresponds to a format consisting of HT-GF-STF, HT-LTF1, HT-SIG, one or more HT-LTF, and Data field, not including L-STF, L-LTF, and L-SIG (not shown).

An example of the VHT PPDU format (IEEE 802.11ac) additionally includes VHT SIG-A, VHT-STF, VHT-LTF, and VHT-SIG-B fields to the basic PPDU format.

An example of the HE PPDU format (IEEE 802.11ax) additionally includes Repeated L-SIG (RL-SIG), HE-SIG-A, HE-SIG-B, HE-STF, HE-LTF(s), Packet Extension (PE) field to the basic PPDU format. Some fields may be excluded or their length may vary according to detailed examples of the HE PPDU format. For example, the HE-SIG-B field is included in the HE PPDU format for multi-user (MU), and the HE-SIG-B is not included in the HE PPDU format for single user (SU). In addition, the HE trigger-based (TB) PPDU format does not include the HE-SIG-B, and the length of the HE-STF field may vary to 8 us. The Extended Range (HE ER) SU PPDU format does not include the HE-SIG-B field, and the length of the HE-SIG-A field may vary to 16 us.

FIGS. 8 to 10 are diagrams for explaining examples of resource units of a WLAN system to which the present disclosure may be applied.

Referring to FIGS. 8 to 10, a resource unit (RU) defined in a wireless LAN system will be described. the RU may include a plurality of subcarriers (or tones). The RU may be used when transmitting signals to multiple STAs based on the OFDMA scheme. In addition, the RU may be defined even when a signal is transmitted to one STA. The RU may be used for STF, LTF, data field of the PPDU, etc.

17

As shown in FIGS. 8 to 10, RUs corresponding to different numbers of tones (i.e., subcarriers) are used to construct some fields of 20 MHz, 40 MHz, or 80 MHz X-PPDUs (X is HE, EHT, etc.). For example, resources may be allocated in RU units shown for the X-STF, X-LTF, and Data field.

FIG. 8 is a diagram illustrating an exemplary allocation of resource units (RUs) used on a 20 MHz band.

As shown at the top of FIG. 8, 26-units (i.e., units corresponding to 26 tones) may be allocated. 6 tones may be used as a guard band in the leftmost band of the 20 MHz band, and 5 tones may be used as a guard band in the rightmost band of the 20 MHz band. In addition, 7 DC tones are inserted in the center band, that is, the DC band, and 26-units corresponding to each of the 13 tones may exist on the left and right sides of the DC band. In addition, 26-unit, 52-unit, and 106-unit may be allocated to other bands. Each unit may be allocated for STAs or users.

The RU allocation of FIG. 8 is utilized not only in a situation for multiple users (MU) but also in a situation for a single user (SU), and in this case, it is possible to use one 242-unit as shown at the bottom of FIG. 8. In this case, three DC tones may be inserted.

In the example of FIG. 8, RUs of various sizes, that is, 26-RU, 52-RU, 106-RU, 242-RU, etc. are exemplified, but the specific size of these RUs may be reduced or expanded. Therefore, in the present disclosure, the specific size of each RU (i.e., the number of corresponding tones) is exemplary and not restrictive. In addition, within a predetermined bandwidth (e.g., 20, 40, 80, 160, 320 MHz, . . .) in the present disclosure, the number of RUs may vary according to the size of the RU. In the examples of FIG. 9 and/or FIG. 10 to be described below, the fact that the size and/or number of RUs may be varied is the same as the example of FIG. 8.

FIG. 9 is a diagram illustrating an exemplary allocation of resource units (RUs) used on a 40 MHz band.

Just as RUs of various sizes are used in the example of FIG. 8, 26-RU, 52-RU, 106-RU, 242-RU, 484-RU, and the like may be used in the example of FIG. 9 as well. In addition, 5 DC tones may be inserted at the center frequency, 12 tones may be used as a guard band in the leftmost band of the 40 MHz band, and 11 tones may be used as a guard band in the rightmost band of the 40 MHz band.

In addition, as shown, when used for a single user, a 484-RU may be used.

FIG. 10 is a diagram illustrating an exemplary allocation of resource units (RUs) used on an 80 MHz band.

Just as RUs of various sizes are used in the example of FIG. 8 and FIG. 9, 26-RU, 52-RU, 106-RU, 242-RU, 484-RU, 996-RU and the like may be used in the example of FIG. 10 as well. In addition, in the case of an 80 MHz PPDUs, RU allocation of HE PPDUs and EHT PPDUs may be different, and the example of FIG. 10 shows an example of RU allocation for 80 MHz EHT PPDUs. The scheme that 12 tones are used as a guard band in the leftmost band of the 80 MHz band and 11 tones are used as a guard band in the rightmost band of the 80 MHz band in the example of FIG. 10 is the same in HE PPDUs and EHT PPDUs. Unlike HE PPDUs, where 7 DC tones are inserted in the DC band and there is one 26-RU corresponding to each of the 13 tones on the left and right sides of the DC band, in the EHT PPDUs, 23 DC tones are inserted into the DC band, and one 26-RU exists on the left and right sides of the DC band. Unlike the HE PPDUs, where one null subcarrier exists between 242-RUs rather than the center band, there are five null subcarriers in the EHT PPDUs. In the HE PPDUs, one 484-RU does

18

not include null subcarriers, but in the EHT PPDUs, one 484-RU includes 5 null subcarriers.

In addition, as shown, when used for a single user, 996-RU may be used, and in this case, 5 DC tones are inserted in common with HE PPDUs and EHT PPDUs.

EHT PPDUs over 160 MHz may be configured with a plurality of 80 MHz subblocks in FIG. 10. The RU allocation for each 80 MHz subblock may be the same as that of the 80 MHz EHT PPDUs of FIG. 10. If the 80 MHz subblock of the 160 MHz or 320 MHz EHT PPDUs is not punctured and the entire 80 MHz subblock is used as part of RU or multiple RU (MRU), the 80 MHz subblock may use 996-RU of FIG. 10.

Here, the MRU corresponds to a group of subcarriers (or tones) composed of a plurality of RUs, and the plurality of RUs constituting the MRU may be RUs having the same size or RUs having different sizes. For example, a single MRU may be defined as 52+26-tone, 106+26-tone, 484+242-tone, 996+484-tone, 996+484+242-tone, 2×996+484-tone, 3×996-tone, or 3×996+484-tone. Here, the plurality of RUs constituting one MRU may correspond to small size (e.g., 26, 52, or 106) RUs or large size (e.g., 242, 484, or 996) RUs. That is, one MRU including a small size RU and a large size RU may not be configured/defined. In addition, a plurality of RUs constituting one MRU may or may not be consecutive in the frequency domain.

When an 80 MHz subblock includes RUs smaller than 996 tones, or parts of the 80 MHz subblock are punctured, the 80 MHz subblock may use RU allocation other than the 996-tone RU.

The RU of the present disclosure may be used for uplink (UL) and/or downlink (DL) communication. For example, when trigger-based UL-MU communication is performed, the STA transmitting the trigger (e.g., AP) may allocate a first RU (e.g., 26/52/106/242-RU, etc.) to a first STA and allocate a second RU (e.g., 26/52/106/242-RU, etc.) to a second STA, through trigger information (e.g., trigger frame or triggered response scheduling (TRS)). Thereafter, the first STA may transmit a first trigger-based (TB) PPDUs based on the first RU, and the second STA may transmit a second TB PPDUs based on the second RU. The first/second TB PPDUs may be transmitted to the AP in the same time period.

For example, when a DL MU PPDUs is configured, the STA transmitting the DL MU PPDUs (e.g., AP) may allocate a first RU (e.g., 26/52/106/242-RU, etc.) to a first STA and allocate a second RU (e.g., 26/52/106/242-RU, etc.) to a second STA. That is, the transmitting STA (e.g., AP) may transmit HE-STF, HE-LTF, and Data field for the first STA through the first RU and transmit HE-STF, HE-LTF, and Data field for the second STA through the second RU, in one MU PPDUs,

Information on the allocation of RUs may be signaled through HE-SIG-B in the HE PPDUs format.

FIG. 11 illustrates an example structure of a HE-SIG-B field.

As shown, the HE-SIG-B field may include a common field and a user-specific field. If HE-SIG-B compression is applied (e.g., full-bandwidth MU-MIMO transmission), the common field may not be included in HE-SIG-B, and the HE-SIG-B content channel may include only a user-specific field. If HE-SIG-B compression is not applied, the common field may be included in HE-SIG-B.

The common field may include information on RU allocation (e.g., RU assignment, RUs allocated for MU-MIMO, the number of MU-MIMO users (STAs), etc.)

The common field may include N*8 RU allocation subfields. Here, N is the number of subfields, N=1 in the case

of 20 or 40 MHz MU PPDU, $N=2$ in the case of 80 MHz MU PPDU, $N=4$ in the case of 160 MHz or 80+80 MHz MU PPDU, etc. One 8-bit RU allocation subfield may indicate the size (26, 52, 106, etc.) and frequency location (or RU index) of RUs included in the 20 MHz band.

For example, if a value of the 8-bit RU allocation subfield is 00000000, it may indicate that nine 26-RUs are sequentially allocated in order from the leftmost to the rightmost in the example of FIG. 8, if the value is 00000001, it may indicate that seven 26-RUs and one 52-RU are sequentially allocated in order from leftmost to rightmost, and if the value is 00000010, it may indicate that five 26-RUs, one 52-RU, and two 26-RUs are sequentially allocated from the leftmost side to the rightmost side.

As an additional example, if the value of the 8-bit RU allocation subfield is 01000y2y1y0, it may indicate that one 106-RU and five 26-RUs are sequentially allocated from the leftmost to the rightmost in the example of FIG. 8. In this case, multiple users/STAs may be allocated to the 106-RU in the MU-MIMO scheme. Specifically, up to 8 users/STAs may be allocated to the 106-RU, and the number of users/STAs allocated to the 106-RU is determined based on 3-bit information (i.e., y2y1y0). For example, when the 3-bit information (y2y1y0) corresponds to a decimal value N , the number of users/STAs allocated to the 106-RU may be $N+1$.

Basically, one user/STA may be allocated to each of a plurality of RUs, and different users/STAs may be allocated to different RUs. For RUs larger than a predetermined size (e.g., 106, 242, 484, 996-tones, . . .), a plurality of users/STAs may be allocated to one RU, and MU-MIMO scheme may be applied for the plurality of users/STAs.

The set of user-specific fields includes information on how all users (STAs) of the corresponding PPDU decode their payloads. User-specific fields may contain zero or more user block fields. The non-final user block field includes two user fields (i.e., information to be used for decoding in two STAs). The final user block field contains one or two user fields. The number of user fields may be indicated by the RU allocation subfield of HE-SIG-B, the number of symbols of HE-SIG-B, or the MU-MIMO user field of HE-SIG-A. A User-specific field may be encoded separately from or independently of a common field.

FIG. 12 is a diagram for explaining a MU-MIMO method in which a plurality of users/STAs are allocated to one RU.

In the example of FIG. 12, it is assumed that the value of the RU allocation subfield is 01000010. This corresponds to the case where $y2y1y0=010$ in 01000y2y1y0. 010 corresponds to 2 in decimal (i.e., $N=2$) and may indicate that 3 ($=N+1$) users are allocated to one RU. In this case, one 106-RU and five 26-RUs may be sequentially allocated from the leftmost side to the rightmost side of a specific 20 MHz band/channel. Three users/STAs may be allocated to the 106-RU in a MU-MIMO manner. As a result, a total of 8 users/STAs are allocated to the 20 MHz band/channel, and the user-specific field of HE-SIG-B may include 8 user fields (i.e., 4 user block fields). Eight user fields may be assigned to RUs as shown in FIG. 12.

The user field may be constructed based on two formats. The user field for a MU-MIMO allocation may be constructed with a first format, and the user field for non-MU-MIMO allocation may be constructed with a second format. Referring to the example of FIG. 12, user fields 1 to 3 may be based on the first format, and user fields 4 to 8 may be based on the second format. The first format and the second format may contain bit information of the same length (e.g., 21 bits).

The user field of the first format (i.e., format for MU-MIMO allocation) may be constructed as follows. For example, out of all 21 bits of one user field, B0-B10 includes the user's identification information (e.g., STA-ID, AID, partial AID, etc.), B11-14 includes spatial configuration information such as the number of spatial streams for the corresponding user, B15-B18 includes Modulation and Coding Scheme (MCS) information applied to the Data field of the corresponding PPDU, B19 is defined as a reserved field, and B20 may include information on a coding type (e.g., binary convolutional coding (BCC) or low-density parity check (LDPC)) applied to the Data field of the corresponding PPDU.

The user field of the second format (i.e., the format for non-MU-MIMO allocation) may be constructed as follows. For example, out of all 21 bits of one user field, B0-B10 includes the user's identification information (e.g., STA-ID, AID, partial AID, etc.), B11-13 includes information on the number of spatial streams (NSTS) applied to the corresponding RU, B14 includes information indicating whether beamforming is performed (or whether a beamforming steering matrix is applied), B15-B18 includes Modulation and Coding Scheme (MCS) information applied to the Data field of the corresponding PPDU, B19 includes information indicating whether DCM (dual carrier modulation) is applied, and B20 may include information on a coding type (e.g., BCC or LDPC) applied to the Data field of the corresponding PPDU.

MCS, MCS information, MCS index, MCS field, and the like used in the present disclosure may be indicated by a specific index value. For example, MCS information may be indicated as index 0 to index 11. MCS information includes information on constellation modulation type (e.g., BPSK, QPSK, 16-QAM, 64-QAM, 256-QAM, 1024-QAM, etc.), and coding rate (e.g., $1/2$, $2/3$, $3/4$, $5/6$, etc.). Information on a channel coding type (e.g., BCC or LDPC) may be excluded from the MCS information.

FIG. 13 illustrates an example of a PPDU format to which the present disclosure may be applied.

The PPDU of FIG. 13 may be referred as various names such as an EHT PPDU, a transmitted PPDU, a received PPDU, a first type or an Nth type PPDU. For example, the PPDU or EHT PPDU of the present disclosure may be referred as various names such as a transmission PPDU, a reception PPDU, a first type or an Nth type PPDU. In addition, the EHT PPU may be used in an EHT system and/or a new wireless LAN system in which the EHT system is improved.

The EHT MU PPDU of FIG. 13 corresponds to a PPDU carrying one or more data (or PSDUs) for one or more users. That is, the EHT MU PPDU may be used for both SU transmission and MU transmission. For example, the EHT MU PPDU may correspond to a PPDU for one receiving STA or a plurality of receiving STAs.

In the EHT TB PPDU of FIG. 13, the EHT-SIG is omitted compared to the EHT MU PPDU. Upon receiving a trigger for UL MU transmission (eg, a trigger frame or TRS), the STA may perform UL transmission based on the EHT TB PPDU format.

In the example of the EHT PPDU format of FIG. 13, L-STF to EHT-LTF correspond to a preamble or a physical preamble, and may be generated/transmitted/received/acquired/decoded in the physical layer.

A Subcarrier frequency spacing of L-STF, L-LTF, L-SIG, RL-SIG, Universal SIGNAL (U-SIG), EHT-SIG field (these are referred to as pre-EHT modulated fields) may be set to 312.5 kHz. A subcarrier frequency spacing of the EHT-STF, EHT-LTF, Data, and PE field (these are referred to as EHT

21

modulated fields) may be set to 78.125 kHz. That is, the tone/subcarrier index of L-STF, L-LTF, L-SIG, RL-SIG, U-SIG, and EHT-SIG field may be indicated in units of 312.5 kHz, and the tone/subcarrier index of EHT-STF, EHT-LTF, Data, and PE field may be indicated in units of 78.125 kHz.

The L-LTF and L-STF of FIG. 13 may be constructed identically to the corresponding fields of the PPDU described in FIGS. 6 to 7.

The L-SIG field of FIG. 13 may be constructed with 24 bits and may be used to communicate rate and length information. For example, the L-SIG field includes a 4-bit Rate field, a 1-bit Reserved bit, a 12-bit Length field, a 1-bit Parity field, and a 6-bit Tail field may be included. For example, the 12-bit Length field may include information on a time duration or a length of the PPDU. For example, a value of the 12-bit Length field may be determined based on the type of PPDU. For example, for a non-HT, HT, VHT, or EHT PPDU, the value of the Length field may be determined as a multiple of 3. For example, for the HE PPDU, the value of the Length field may be determined as a multiple of 3+1 or a multiple of 3+2.

For example, the transmitting STA may apply BCC encoding based on a coding rate of $\frac{1}{2}$ to 24-bit information of the L-SIG field. Thereafter, the transmitting STA may obtain 48-bit BCC coded bits. BPSK modulation may be applied to 48-bit coded bits to generate 48 BPSK symbols. The transmitting STA may map 48 BPSK symbols to any location except for a pilot subcarrier (e.g., {subcarrier index -21, -7, +7, +21}) and a DC subcarrier (e.g., {subcarrier index 0}). As a result, 48 BPSK symbols may be mapped to subcarrier indices -26 to -22, -20 to -8, -6 to -1, +1 to +6, +8 to +20, and +22 to +26. The transmitting STA may additionally map the signals of {-1, -1, -1, 1} to the subcarrier index {-28, -27, +27, +28}. The above signal may be used for channel estimation in the frequency domain corresponding to {-28, -27, +27, +28}.

The transmitting STA may construct RL-SIG which is constructed identically to L-SIG. For RL-SIG, BPSK modulation is applied. The receiving STA may recognize that the received PPDU is a HE PPDU or an EHT PPDU based on the existence of the RL-SIG.

After the RL-SIG of FIG. 13, a Universal SIG (U-SIG) may be inserted. The U-SIG may be referred as various names such as a first SIG field, a first SIG, a first type SIG, a control signal, a control signal field, and a first (type) control signal, etc.

The U-SIG may include N-bit information and may include information for identifying the type of EHT PPDU. For example, U-SIG may be configured based on two symbols (e.g., two consecutive OFDM symbols). Each symbol (e.g., OFDM symbol) for the U-SIG may have a duration of 4 us, and the U-SIG may have a total 8 us duration. Each symbol of the U-SIG may be used to transmit 26 bit information. For example, each symbol of the U-SIG may be transmitted and received based on 52 data tones and 4 pilot tones.

Through the U-SIG (or U-SIG field), for example, A bit information (e.g., 52 un-coded bits) may be transmitted, the first symbol of the U-SIG (e.g., U-SIG-1) may transmit the first X bit information (e.g., 26 un-coded bits) of the total A bit information, and the second symbol of the U-SIG (e.g., U-SIG-2) may transmit the remaining Y-bit information (e.g., 26 un-coded bits) of the total A-bit information. For example, the transmitting STA may obtain 26 un-coded bits included in each U-SIG symbol. The transmitting STA may generate 52-coded bits by performing convolutional encod-

22

ing (e.g., BCC encoding) based on a rate of $R=\frac{1}{2}$, and perform interleaving on the 52-coded bits. The transmitting STA may generate 52 BPSK symbols allocated to each U-SIG symbol by performing BPSK modulation on the interleaved 52-coded bits. One U-SIG symbol may be transmitted based on 56 tones (subcarriers) from subcarrier index -28 to subcarrier index +28, except for DC index 0. The 52 BPSK symbols generated by the transmitting STA may be transmitted based on the remaining tones (subcarriers) excluding pilot tones -21, -7, +7, and +21 tones.

For example, the A bit information (e.g., 52 un-coded bits) transmitted by the U-SIG includes a CRC field (e.g., a 4-bit field) and a tail field (e.g., 6 bit-length field). The CRC field and the tail field may be transmitted through the second symbol of the U-SIG. The CRC field may be constructed based on 26 bits allocated to the first symbol of U-SIG and 16 bits remaining except for the CRC/tail field in the second symbol, and may be constructed based on a conventional CRC calculation algorithm. In addition, the tail field may be used to terminate the trellis of the convolution decoder, and for example, the tail field may be set to 0.

A bit information (e.g., 52 un-coded bits) transmitted by the U-SIG (or U-SIG field) may be divided into version-independent bits and version-dependent bits. For example, a size of the version-independent bits may be fixed or variable. For example, the version-independent bits may be allocated only to the first symbol of U-SIG, or the version-independent bits may be allocated to both the first symbol and the second symbol of U-SIG. For example, the version-independent bits and the version-dependent bits may be referred as various names such as a first control bit and a second control bit, etc.

For example, the version-independent bits of the U-SIG may include a 3-bit physical layer version identifier (PHY version identifier). For example, the 3-bit PHY version identifier may include information related to the PHY version of the transmitted/received PPDU. For example, the first value of the 3-bit PHY version identifier may indicate that the transmission/reception PPDU is an EHT PPDU. In other words, when transmitting the EHT PPDU, the transmitting STA may set the 3-bit PHY version identifier to a first value. In other words, the receiving STA may determine that the received PPDU is an EHT PPDU based on the PHY version identifier having the first value.

For example, the version-independent bits of U-SIG may include a 1-bit UL/DL flag field. A first value of the 1-bit UL/DL flag field is related to UL communication, and a second value of the UL/DL flag field is related to DL communication.

For example, the version-independent bits of the U-SIG may include information on the length of a transmission opportunity (TXOP) and information on a BSS color ID.

For example, if the EHT PPDU is classified into various types (e.g., EHT PPDU related to SU mode, EHT PPDU related to MU mode, EHT PPDU related to TB mode, EHT PPDU related to Extended Range transmission, etc.), information on the type of EHT PPDU may be included in the version-dependent bits of the U-SIG.

For example, the U-SIG may include information on 1) a bandwidth field containing information on a bandwidth, 2) a field containing information on a MCS scheme applied to EHT-SIG, 3) an indication field containing information related to whether the DCM technique is applied to the EHT-SIG, 4) a field containing information on the number of symbols used for EHT-SIG, 5) a field containing information on whether EHT-SIG is constructed over all bands, 6) a field

containing information on the type of EHT-LTF/STF, and 7) a field indicating the length of EHT-LTF and CP length.

Preamble puncturing may be applied to the PPDU of FIG. 13. Preamble puncturing may mean transmission of a PPDU for which no signal is present in one or more 20 MHz subchannels among the bandwidth of the PPDU. Preamble puncturing may be applied to a PPDU transmitted to one or more users. For example, the resolution of preamble puncturing may be 20 MHz for EHT MU PPDUs in OFDMA transmissions with bandwidths greater than 40 MHz and non-OFDMA transmissions with 80 MHz and 160 MHz bandwidths. That is, in the above case, puncturing on a subchannel smaller than 242-tone RU may not be allowed. In addition, for an EHT MU PPDU in non-OFDMA transmission with a bandwidth of 320 MHz, the resolution of preamble puncturing may be 40 MHz. That is, puncturing for a subchannel smaller than 484-tone RU in a 320 MHz bandwidth may not be allowed. In addition, preamble puncturing may not be applied to the primary 20 MHz channel in the EHT MU PPDU.

For example, for an EHT MU PPDU, information on preamble puncturing may be included in the U-SIG and/or the EHT-SIG. For example, the first field of the U-SIG may include information on the contiguous bandwidth of the PPDU, and the second field of the U-SIG may include information on preamble puncturing applied to the PPDU.

For example, the U-SIG and the EHT-SIG may include information on preamble puncturing based on the following method. If the bandwidth of the PPDU exceeds 80 MHz, the U-SIG may be individually constructed in units of 80 MHz. For example, if the bandwidth of the PPDU is 160 MHz, the PPDU may include a first U-SIG for a first 80 MHz band and a second U-SIG for a second 80 MHz band. In this case, the first field of the first U-SIG includes information on the 160 MHz bandwidth, and the second field of the first U-SIG includes information on preamble puncturing applied to the first 80 MHz band (i.e., information on a preamble puncturing pattern). In addition, the first field of the second U-SIG includes information on a 160 MHz bandwidth, and the second field of the second U-SIG includes information on preamble puncturing applied to a second 80 MHz band (i.e., information on a preamble puncturing pattern). The EHT-SIG following the first U-SIG may include information on preamble puncturing applied to the second 80 MHz band (i.e., information on a preamble puncturing pattern), and the EHT-SIG following the second U-SIG may include information on preamble puncturing applied to the first 80 MHz band (i.e., information on a preamble puncturing pattern).

Additionally or alternatively, the U-SIG and the EHT-SIG may include information on preamble puncturing based on the following method. The U-SIG may include information on preamble puncturing for all bands (i.e., information on a preamble puncturing pattern). That is, EHT-SIG does not include information on preamble puncturing, and only U-SIG may include information on preamble puncturing (i.e., information on a preamble puncturing pattern).

U-SIG may be constructed in units of 20 MHz. For example, if an 80 MHz PPDU is constructed, the U-SIG may be duplicated. That is, the same 4 U-SIGs may be included in the 80 MHz PPDU. PPDUs exceeding 80 MHz bandwidth may include different U-SIGs.

The EHT-SIG of FIG. 13 may include control information for the receiving STA. EHT-SIG may be transmitted through at least one symbol, and one symbol may have a length of 4 us. Information on the number of symbols used for EHT-SIG may be included in U-SIG.

The EHT-SIG may include technical features of HE-SIG-B described through FIGS. 11 and 12. For example, EHT-SIG, like the example of FIG. 8, may include a common field and a user-specific field. The Common field of the EHT-SIG may be omitted, and the number of user-specific fields may be determined based on the number of users.

As in the example of FIG. 11, the common field of the EHT-SIG and the user-specific field of the EHT-SIG may be coded separately. One user block field included in the user-specific field may contain information for two user fields, but the last user block field included in the user-specific field may contain one or two user fields. That is, one user block field of the EHT-SIG may contain up to two user fields. As in the example of FIG. 12, each user field may be related to MU-MIMO allocation or non-MU-MIMO allocation.

In the same way as in the example of FIG. 11, the common field of the EHT-SIG may include a CRC bit and a Tail bit. The length of the CRC bit may be determined as 4 bits, and the length of the tail bit is determined by 6 bits and may be set to 000000.

As in the example of FIG. 11, the common field of the EHT-SIG may include RU allocation information. RU allocation information may mean information on the location of an RU to which a plurality of users (i.e., a plurality of receiving STAs) are allocated. RU allocation information may be configured in units of 9 bits (or N bits).

A mode in which a common field of EHT-SIG is omitted may be supported. The mode in which the common field of the EHT-SIG is omitted may be referred as a compressed mode. When the compressed mode is used, a plurality of users (i.e., a plurality of receiving STAs) of the EHT PPDU may decode the PPDU (e.g., the data field of the PPDU) based on non-OFDMA. That is, a plurality of users of the EHT PPDU may decode a PPDU (e.g., a data field of the PPDU) received through the same frequency band. When a non-compressed mode is used, multiple users of the EHT PPDU may decode the PPDU (e.g., the data field of the PPDU) based on OFDMA. That is, a plurality of users of the EHT PPDU may receive the PPDU (e.g., the data field of the PPDU) through different frequency bands.

EHT-SIG may be constructed based on various MCS scheme. As described above, information related to the MCS scheme applied to the EHT-SIG may be included in the U-SIG. The EHT-SIG may be constructed based on the DCM scheme. The DCM scheme may reuse the same signal on two subcarriers to provide an effect similar to frequency diversity, reduce interference, and improve coverage. For example, modulation symbols to which the same modulation scheme is applied may be repeatedly mapped on available tones/subcarriers. For example, modulation symbols (e.g., BPSK modulation symbols) to which a specific modulation scheme is applied may be mapped to first contiguous half tones (e.g., 1st to 26th tones) among the N data tones (e.g., 52 data tones) allocated for EHT-SIG, and modulation symbols (e.g., BPSK modulation symbols) to which the same specific modulation scheme is applied may be mapped to the remaining contiguous half tones (e.g., 27th to 52nd tones). That is, a modulation symbol mapped to the 1st tone and a modulation symbol mapped to the 27th tone are the same. As described above, information related to whether the DCM scheme is applied to the EHT-SIG (e.g., a 1-bit field) may be included in the U-SIG. The EHT-STF of FIG. 13 may be used to enhance automatic gain control (AGC) estimation in a MIMO environment or an OFDMA envi-

25

ronment. The EHT-LTF of FIG. 13 may be used to estimate a channel in a MIMO environment or an OFDMA environment.

Information on the type of STF and/or LTF (including information on a guard interval (GI) applied to LTF) may be included in the U-SIG field and/or the EHT-SIG field of FIG. 13.

The PPDU (i.e., EHT PPDU) of FIG. 13 may be constructed based on an example of RU allocation of FIGS. 8 to 10.

For example, a EHT PPDU transmitted on a 20 MHz band, that is, a 20 MHz EHT PPDU may be constructed based on the RU of FIG. 8. That is, a RU location of EHT-STF, EHT-LTF, and data field included in the EHT PPDU may be determined as shown in FIG. 8. A EHT PPDU transmitted on a 40 MHz band, that is, a 40 MHz EHT PPDU may be constructed based on the RU of FIG. 9. That is, a RU location of EHT-STF, EHT-LTF, and data field included in the EHT PPDU may be determined as shown in FIG. 9.

The EHT PPDU transmitted on the 80 MHz band, that is, the 80 MHz EHT PPDU may be constructed based on the RU of FIG. 10. That is, a RU location of EHT-STF, EHT-LTF, and data field included in the EHT PPDU may be determined as shown in FIG. 10. The tone-plan for 80 MHz in FIG. 10 may correspond to two repetitions of the tone-plan for 40 MHz in FIG. 9.

The tone-plan for 160/240/320 MHz may be configured in the form of repeating the pattern of FIG. 9 or 10 several times.

The PPDU of FIG. 13 may be identified as an EHT PPDU based on the following method.

The receiving STA may determine the type of the received PPDU as the EHT PPDU based on the following. For example, when 1) the first symbol after the L-LTF signal of the received PPDU is BPSK, 2) RL-SIG in which the L-SIG of the received PPDU is repeated is detected, and 3) the result of applying the modulo 3 calculation to the value of the Length field of the L-SIG of the received PPDU (i.e., the remainder after dividing by 3) is detected as 0, the received PPDU may be determined as a EHT PPDU. When the received PPDU is determined to be an EHT PPDU, the receiving STA may determine the type of the EHT PPDU based on bit information included in symbols subsequent to the RL-SIG of FIG. 13. In other words, the receiving STA may determine the received PPDU as a EHT PPDU, based on 1) the first symbol after the L-LTF signal, which is BPSK, 2) RL-SIG contiguous to the L-SIG field and identical to the L-SIG, and 3) L-SIG including a Length field in which the result of applying modulo 3 is set to 0.

For example, the receiving STA may determine the type of the received PPDU as the HE PPDU based on the following. For example, when 1) the first symbol after the L-LTF signal is BPSK, 2) RL-SIG in which L-SIG is repeated is detected, and 3) the result of applying modulo 3 to the length value of L-SIG is detected as 1 or 2, the received PPDU may be determined as a HE PPDU.

For example, the receiving STA may determine the type of the received PPDU as non-HT, HT, and VHT PPDU based on the following. For example, when 1) the first symbol after the L-LTF signal is BPSK and 2) RL-SIG in which L-SIG is repeated is not detected, the received PPDU may be determined as non-HT, HT, and VHT PPDU.

In addition, when the receiving STA detects an RL-SIG in which the L-SIG is repeated in the received PPDU, it may be determined that the received PPDU is a HE PPDU or an EHT PPDU. In this case, if the rate (6 Mbps) check fails, the received PPDU may be determined as a non-HT, HT, or

26

VHT PPDU. If the rate (6 Mbps) check and parity check pass, when the result of applying modulo 3 to the Length value of L-SIG is detected as 0, the received PPDU may be determined as an EHT PPDU, and when the result of Length mod 3 is not 0, it may be determined as a HE PPDU.

The PPDU of FIG. 13 may be used to transmit and receive various types of frames. For example, the PPDU of FIG. 13 may be used for (simultaneous) transmission and reception of one or more of a control frame, a management frame, or a data frame.

Multi-Link Operation

Hereinafter, a multi-link operation supported by a STA according to the present disclosure will be described.

A STA (an AP STA and/or a non-AP STA) described in the present disclosure may support multi link (ML) communication. ML communication may refer to communication supporting a plurality of links. A link related to ML communication may include a channel (e.g., 20/40/80/160/240/320 MHz channels) in a frequency band in which a STA operates (e.g., a 2.4 GHz band, a 5 GHz band, a 6 GHz band, etc.). A plurality of links used for ML communication may be configured in various ways. For example, a plurality of links supported by one STA for ML communication may belong to the same frequency band or belong to a different frequency band. In addition, each link may correspond to a frequency unit in a predetermined size (e.g., a channel, a subchannel, a RU, etc.). In addition, all or part of a plurality of links may be a frequency unit in the same size or may be a frequency unit in a different size.

When one STA supports a plurality of links, a transmitting or receiving device supporting each link may operate like one logical STA. In other words, a MLD refers to a device which has at least one affiliated STA as a logical entity and has a single MAC service access point (SAP) for one MAC data service and logical link control (LLC). A non-AP MLD refers to a MLD that each STA affiliated with a corresponding MLD is a non-AP STA. A multi-radio non-AP MLD refers to a non-AP MLD that supports reception or exchange of a frame in at least one link at a time. An AP MLD refers to a MLD that each STA affiliated with a corresponding MLD is an AP STA.

A multi-link operation (MLO) may enable a non-AP MLD to discover, authenticate and associate an AP MLD and set up a plurality of links. Based on a supported capability exchanged during an association procedure, each link may enable channel access and frame exchange between a non-AP MLD and an AP MLD. A STA affiliated with a MLD may select and manage its capability and operation parameter independently from other STA(s) affiliated with the same MLD.

Through a multi-link setup process, an AP MLD and/or a non-AP MLD may transmit or receive link-related information which may be supported by a corresponding MLD. Link-related information may include at least one of whether it is a simultaneous transmit and receive (STR) operation capable of simultaneous transmission or reception on a plurality of links or a non-simultaneous transmit and receive (NSTR) operation incapable of simultaneous transmission or reception, information on the number/upper limit of UL/DL links, information on a location/a band/a resource of an UL/DL link, information on a frame type (e.g., management, control, data) available or preferred in at least one UL/DL link, information on an ACK policy available or preferred in at least one UL/DL link or information on a traffic identifier (TID) available in at least one UL/DL link supported by a corresponding MLD.

An AP MLD (e.g., a NSTR mobile AP MLD) may configure one link among a plurality of links as a primary link. An AP MLD may perform a beacon frame, a probe response frame and a group addressed data frame only on a primary link. The remaining other link(s) of a plurality of links may be referred to as a non-primary link. An AP MLD operating on a non-primary link may operate not to transmit a beacon frame or a probe response frame. In addition, a non-AP MLD may perform frame exchange during authentication, (re)association and 4-way handshaking only on a primary link.

When at least one traffic identifier (TID) is mapped to a corresponding link through a multi-link setup process, a setup link may be defined as being enabled and when there is no TID mapped to a corresponding link, a setup link may be defined as being disabled. A TID should be always mapped to at least one setup link unless admission control is used. Basically, a TID is mapped to all setup links, so all setup links may be activated.

When a link is activated, a corresponding link may be used for frame exchange according to a power state of a non-AP STA operating in a corresponding link. Only a MSDU or an A-MSDU with a TID mapped to an active link may be transmitted in a corresponding link. A management frame and a control frame may be transmitted only in an active link.

When a link is deactivated, a corresponding link may not be used for frame exchange by including a management frame for both a DL and an UL.

In a multi-link setup process, activation/deactivation of each link may be indicated through TID-to-Link mapping. TID-to-Link mapping may be performed in a default mapping mode or/and a negotiation mapping mode.

Random Access in a Multi-Link Operation

One STA among STAs belonging to a MLD may provide information on at least one link other than its link for one multi-link setup (i.e., simultaneous association on a plurality of links through exchange between an association request/response frame on one link). To provide this information, a multi-link (ML) element may be defined.

FIG. 14 exemplarily shows a structure of a ML element to which the present disclosure may be applied.

In a ML element, an element ID field and an element ID extension field may have a specific value (e.g., 255 and 107) showing that they are a ML element and a length field may have a value showing a length of the remaining fields (e.g., an octet unit) excluding an element ID field and a length field.

A multi-link control field is defined as having a size of 2 octets and may include a 3-bit type subfield, a 1-bit reserved bit and a 12-bit presence bitmap subfield. A type subfield may have a value indicating one of types such as basic, a probe request, a reconfiguration, a tunneled direct-link setup (TDLS), priority access, etc. A presence bitmap subfield shows whether there are a variety of subfield(s) within a common information field and may be defined in a different format according to various variants (or types described above) of a ML element.

A common information field is defined as having a variable size and may include a 6-octet MLD MAC address subfield, and this subfield may have a value specifying a MAC address of a MLD to which a STA transmitting a basic ML element belongs. In addition, a link ID information subfield, a BSS parameter change count subfield, a medium synchronization delay information subfield, an enhanced

multi-link (EML) capability subfield, a MLD capability subfield, etc. may or may not be included in a common information field.

A link information field is defined as having a variable size, and may include link specific information and may exist optionally. If a link information field exists, it may include at least one sub-element. A format and order of a sub-element may be defined in various ways. As an example of an optional sub-element ID for a basic variant ML element, 0, a value of a sub-element ID, corresponds to a name of a per-STA profile and is extensible, and that value 221 corresponds to a vendor-specific name and whether it may be extended may be determined by a vendor, and the remaining values 1-220 and 222-255 may be reserved.

A per-STA profile sub-element may include a 1-octet sub-element ID subfield, a 1-octet length subfield, a 2-octet STA control subfield, a variable-sized STA information subfield and a variable-sized STA profile subfield. A STA control subfield may include information such as a link ID, whether a complete profile is included, whether a STA MAC address exists, etc. A STA information subfield may include information such as a STA MAC address, etc. A STA profile subfield may include information included in a probe response or probe request frame body, information included in a (re)association response or (re)association request frame body, etc. according to whether a reported STA is an AP STA or a non-AP STA.

A format of a ML element in FIG. 14 is illustrative, and a order, a name, a size, etc. of a field/a subfield may be changed, an additional field/subfield may be further defined and some fields/subfields may be excluded. In other words, a common information field may include common information between STAs in a MLD, and a link information field may include specific information on each STA/link (e.g., in a per-STA profile sub-element including a link ID corresponding to a corresponding STA).

FIG. 15 is a diagram showing an exemplary relationship between a multiple BSSID set and a multi-link device to which the present disclosure may be applied.

A multiple BSSID operation may include one access point (AP) operating physically by generating a plurality of virtual APs in one link (or channel). In the following description, a multiple BSSID may be indicated as a MBSSID.

A MBSSID set includes at least one non-transmitted BSSID, and one transmitted BSSID may be defined.

Information on a plurality of (virtual) APs may be provided by being included in one management frame (e.g., a beacon, a probe response, a (re)association response), and for this purpose, a MBSSID element may be defined.

In an example of FIG. 15, x, y, p, q, r, a and b correspond to an illustrative value of a BSSID, [T] represents a transmitted BSSID (or a Tx BSSID) and a BSSID where [T] is not indicated represents a non-transmitted BSSID (or a non-Tx BSSID).

FIG. 16 is a diagram for describing an example of a ML element of a MBSSID element to which the present disclosure may be applied.

In an example of FIG. 15, when BSSID-a of MLD 1 belongs to a MBSSID set and corresponds to a Tx BSSID, in order to provide information on a non-Tx BSSID such as BSSID-b and BSSID-c and a MLD to which a corresponding non-Tx BSSID belongs, as in an example of FIG. 16, a ML element may be included in a profile of an AP corresponding to each non-Tx BSSID of a MBSSID element transmitted by an AP corresponding to BSSID-a.

Specifically, FIG. 16 corresponds to an example of inheritance of a complete per-STA profile for a MBSSID scenario.

For example, FIG. 16 illustratively shows inheritance when a per-STA profile carries a complete profile from a basic ML element included in a non-Tx BSSID profile of a MBSSID element. A corresponding example shows a management frame transmitted by an AP corresponding to a Tx BSSID. A management frame carries at least one element having each element ID, and an element ID is indicated as A, B, C, . . . in parentheses. A corresponding frame also carries a MBSSID element including a profile for Non-Tx BSSID N. A Non-Tx BSSID profile includes a basic ML element carrying a complete profile for AP x. BSSID N inherits elements having an ID of B, C and E. Elements having an ID of D and F are specific to BSSID N and appear in its non-Tx BSSID profile. In addition, BSSID N does not inherit elements included in an element having an ID of A and a non-inheritance element. Since a value of element F for BSSID N is not the same as advertised by a Tx BSSID, a corresponding element is included in a profile for BSSID N. An element having an ID of Y is specific to BSSID N and is included in its profile. AP x inherits elements having an ID of D and F from BSSID N, and indirectly inherits an element having an ID of C from a Tx BSSID (e.g., through inheritance of BSSID N). AP x does not inherit element A (equal to a non-Tx BSSID). An element having an ID of B and Y is specific to AP x and is included in its profile. In addition, AP x does not inherit element E from a Tx BSSID, and does not inherit an ID included in a non-inheritance element present in its profile.

In other words, as described above, one AP within one MLD may transmit information of other AP(s) within the same MLD to a STA by including it in a ML element. In addition, as in an example of FIG. 15, when a MBSSID set and a MLD are mixed, a ML element may be included in a MBSSID element and provided from an AP to a STA.

Here, since a ML element basically includes information on multiple APs, it may exceed 255 octets if the number of AP STAs is large and/or the number of elements to be inherited is small. Generally, fragment may be applied to an element exceeding 255 octets, but fragment may not be applied to a MBSSID element basically, and when fragment is applied to a non-Tx BSSID profile, a plurality of MBSSID elements may be used.

In other words, when a non-Tx BSSID includes a ML element, if fragment for a MBSSID element is allowed, step-by-step fragment for a plurality of (sub)elements is required, which may require a complex rule and make it difficult for a non-AP STA to decode (based on fragment) a MBSSID element transmitted from an AP STA. Accordingly, a new method is required in which an AP provides ML elements without applying fragment to a MBSSID element.

FIG. 17 is a diagram for describing a method of receiving AP-related information according to the present disclosure.

In S1710, a STA may transmit a request frame including information indicating at least one of a first AP or a first MLD.

For example, a request frame may address a first AP (e.g., a receiving address (RA)/a destination address (DA) of a request frame may be configured as an address value of a first AP). Alternatively, a request frame may address a second AP and include identification information of a first MLD.

For example, a first AP may be an AP corresponding to a non-Tx BSSID, and a second AP may be an AP corresponding to a Tx BSSID. In addition, a first AP may belong to a first MLD, and a second AP may belong to a second MLD.

In S1720, a STA may receive a response frame in response to a request frame.

For example, a response frame may be received from a first AP, and this response frame may include a first ML element related to at least one of a first AP or a first MLD (or AP(s) belonging to a first MLD) (i.e., a first AP/a first MLD) (Embodiment 1 described later). Alternatively, a response frame may be received from a second AP, and this response frame may include a first ML element related to at least one of a first AP or a first MLD (i.e., a first AP/a first MLD), and a second ML element related to at least one of a second AP or a second MLD (or AP(s) belonging to a second MLD) (i.e., a second AP/a second MLD) (refer to Embodiment 2 or 3 described later).

For example, a first ML element and a second ML element may be configured based on a different format or a different variant/type. In this case, a first ML element may have a format defined to include information on at least one of a first AP or a first MLD, and a second ML element may have a format defined to include information on at least one of a second AP or a second MLD (refer to Embodiment 2 described later).

Alternatively, a first ML element and the second ML element may be configured based on the same format or the same variant/type. In this case, a first ML element may include information indicating that it includes information on at least one of a first AP or a first MLD (refer to Embodiment 3 described later).

For example, a response frame may include a MBSSID element, and a first ML element and a second ML element may be included in a frame body of a response frame.

If a size of a first ML element exceeds 255 octets, a fragment for a first ML element may be generated. In addition, if a size of a second ML element exceeds 255 octets, a fragment for a second ML element may be generated.

FIG. 18 is a diagram for describing a method of transmitting AP-related information according to the present disclosure.

In S1810, an AP may receive a request frame including information indicating at least one of a first AP or a first MLD from a STA.

In S1820, an AP may transmit a response frame in response to a request frame to a STA.

For example, when a request frame addresses a first AP (e.g., a receiving address (RA)/a destination address (DA) of a request frame is configured as an address value of a first AP), an AP receiving a request frame may be a first AP and an AP transmitting a response frame may be a second AP. Alternatively, when a request frame addresses a second AP and includes identification information of a first MLD, an AP receiving a request frame may be a second AP and an AP transmitting a response frame may also be a second AP.

For example, a first AP may be an AP corresponding to a non-Tx BSSID, and a second AP may be an AP corresponding to a Tx BSSID. In addition, a first AP may belong to a first MLD, and a second AP may belong to a second MLD.

Regarding a response frame, a description of S1720 in an example of FIG. 17 may also be applied to S1820 in FIG. 18, and an overlapping description is omitted.

In the above-described examples, a request frame may be a probe request frame, and a response frame may be a probe response frame.

Hereinafter, specific examples of the present disclosure for a method of transmitting or receiving information related to an access point supporting a MBSSID set and a MLD operation are described.

It is described by assuming a probe request frame and a probe response frame to request and respond to AP infor-

mation for a MBSSID set, but a scope of the present disclosure include application of examples of the present disclosure to another management frame other than a probe request/response frame (e.g., a (re)association request/response frame).

Unless there is a risk of confusion in the following description, an AP with a Non-Tx BSSID may be abbreviated as a Non-Tx BSSID, and similarly, an AP with a Tx BSSID may be abbreviated as a Tx BSSID.

For example, if a MLD ID is not included or defined in a probe request variant ML element, when a STA requests information on a non-Tx BSSID, a receiving address (RA) field and/or a destination address (DA) field may be configured as a value corresponding to a Non-Tx BSSID in a probe request frame. In this case, instead of a Non-Tx BSSID that received a probe request frame, a Tx BSSID may transmit a probe response frame including a MBSSID IE to a corresponding STA.

As another example, if a MLD ID is not included or defined in a probe request variant ML element, when a STA requests information on a non-Tx BSSID, a RA/DA field may be configured as a value corresponding to a Tx BSSID in a probe request frame. In this case, a Tx BSSID that received a probe request frame may transmit a probe response frame including a MBSSID IE to a corresponding STA.

When a ML element is included in a probe response frame body (i.e., when an AP transmitting a ML element (e.g., a Tx BSSID) transmits a ML element including its information and/or information of other AP(s) belonging to a MLD to which it belongs by including it in a probe response frame body), a ML element may be fragmented when a size of a ML element is larger than a predetermined threshold, and in this case, a complex problem related to a MBSSID may not occur. In other words, there is no problem in performing a fragment of a ML element itself which includes information on itself or another AP belonging to a MLD to which it belongs in a Tx BSSID or a Non-Tx BSSID that transmits it.

In contrast, when an AP (e.g., a Tx BSSID) transmits information on another MLD to which it does not belong (e.g., a MLD to which a non-Tx BSSID belongs) by including it in a ML element of a probe response frame body, a complex problem may occur. For example, a MBSSID element may include a profile for at least one non-Tx BSSID, and each non-Tx BSSID profile may include a ML element. In this case, when a ML element included in a MBSSID element exceeds 255 octets and a fragment is applied, it is necessary to define a complex rule to decode it.

By considering it, when a probe request addresses a first AP (e.g., a non-Tx BSSID) or when a probe request addresses a second AP (e.g., a Tx BSSID) and includes information indicating a first MLD (e.g., when a MLD ID of a probe request variant ML element indicates a MLD to which a first AP (e.g., a non-Tx BSSID) belongs), a method of using a probe response frame to provide a MBSSID element including a ML element in a new method that does not cause a complex problem even if a size of a ML element exceeds 255 octets is described below.

Embodiment 1

This embodiment relates to a method in which a non-Tx BSSID provides information related to at least one AP by defining a new frame type.

A new management frame type (e.g., a multi-link probe response frame) may be defined, and a non-Tx BSSID may

be defined as being capable of transmitting only the new type of management frame. In other words, a non-Tx BSSID does not basically transmit a management frame, but a new type of management frame may be defined as being able to transmit it exceptionally.

In this embodiment, since a non-Tx BSSID directly provides AP-related information, it may be applied by modifying a response rule and definition of a new frame type in the existing method in which a Tx BSSID provides AP-related information.

FIG. 19 is a diagram showing an example of an AP-related information request and response process according to the present disclosure.

STA 1 assumes a case in which information on a MLD (e.g., MLD 1) to which AP 1-a belongs and AP b belonging to a corresponding MLD is requested to AP 1-a (non-Tx BSSID) belonging to the same MBSSID set as AP 1 (Tx BSSID) operating in link 1 (L1). In this case, AP 1-a is a non-Tx BSSID, but may transmit a new type of probe response (e.g., a ML probe response). Accordingly, AP 1-a may be transmitted to STA 1 through a probe response frame including a ML element (here, a (existing) basic ML element may be used as a ML element) including information on another AP (e.g., AP b) belonging to its MLD.

If a corresponding ML element exceeds 255 octets, AP 1-a may apply a fragment to a ML element and transmit it to STA 1.

Embodiment 2

This embodiment relates to a method in which a Tx BSSID provides information related to at least one AP by defining a new ML element type.

When transmitting information on a MLD to which a Non-Tx BSSID belongs and other APs of a corresponding MLD, a Tx BSSID may use a new type of ML element (e.g., a non-Tx variant ML element). It may be notified that information included in a new type of ML element includes information on a Non-Tx BSSID, information on a MLD to which a Non-Tx BSSID belongs and information on other requested AP(s) (e.g., other AP(s) belonging to a MLD to which a Non-Tx BSSID belongs).

Accordingly, a probe response frame transmitted by a Tx BSSID may include two ML elements of a different type/format/variant. For example, a basic variant ML element including common information on a MLD to which a Tx BSSID belongs may be provided as before. Additionally, a new type (e.g., non-Tx variant) ML element may be provided that includes information on requested AP(s) belonging to the same MLD as a non-Tx BSSID and information on a corresponding MLD.

Information on an AP (e.g., a Tx BSSID) transmitting a ML element may be included in a probe response frame body. In other words, information of a Tx BSSID is not included in a ML element, but may be included in a probe response frame body itself.

When a complete profile of other AP(s) belonging to the same MLD as an AP transmitting a ML element is requested, an inheritance rule may be applied from information of an AP transmitting it. According to the above-described examples, information of a Tx BSSID is included in a probe response frame body, and it may be difficult to apply an inheritance rule to AP information included in a non-Tx ML element. Accordingly, a first per-STA profile sub-element of a link information field of a non-Tx variant ML element may include information on a non-Tx BSSID designated by a STA, and at least one subsequent per-STA profile sub-

element may include information on at least one other (requested) AP(s) belonging to the same MLD as a corresponding non-Tx BSSID, respectively. For the at least one subsequent per-STA profile sub-element, an inheritance rule based on information of the first per-STA profile sub-element may be applied.

According to Embodiment 2, as in the existing operation, a Tx BSSID transmits a frame responding to a STA's request, so there is no need to modify a basic response rule, but an additional type for a ML element must be defined, and a plurality of ML elements of a different type need to be defined to be included in a probe response frame.

FIG. 20 is a diagram showing an additional example of an AP-related information request and response process according to the present disclosure.

STA 1 assumes a case in which information on a MLD (e.g., MLD 1) to which AP 1-a belongs and AP b belonging to a corresponding MLD is requested to AP 1-a (non-Tx BSSID) belonging to the same MBSSID set as AP 1 (Tx BSSID) operating in link 1 (L1). In this case, AP 1-a may not transmit a probe response because it is a non-TX BSSID, and AP 1, a Tx BSSID, may transmit a probe response frame. A probe response frame may include a basic ML element and a non-Tx ML element. A basic ML element may include common information on a MLD (e.g., MLD 2) to which a Tx BSSID belongs. A non-Tx ML element may include common information on a MLD (e.g., MLD 1) to which a non-Tx BSSID belongs, and link information on APs (e.g., AP 1-a and AP b) belonging to a corresponding MLD.

When a basic ML element and/or a non-Tx ML element exceeds 255 octets, AP 1 may apply a fragment to each corresponding ML element and transmit it to STA 1.

Embodiment 3

This embodiment relates to a method in which a Tx BSSID provides information related to at least one AP by utilizing a plurality of basic ML elements.

Embodiment 3 is similar to Embodiment 2, but unlike Embodiment 2 which defined a new type of ML element, Embodiment 3 may utilize the existing basic variant ML element to provide non-Tx BSSID related information. In this case, a basic variant ML element may include additional indication information showing that a corresponding ML element includes information related to a non-Tx BSSID (or a MLD to which a non-Tx BSSID belongs). For example, the additional indication information may be expressed by using a reserved bit of a multi-link control field, a type field, a 1-bit of a presence field, etc.

For Embodiment 3, by replacing a new type of ML element (e.g., a non-Tx variant ML element) in Embodiment 2 with a basic variant ML element including the additional indication information, a description included in Embodiment 2 may be equally applied to Embodiment 3.

According to Embodiment 3, as in the existing operation, a Tx BSSID transmits a frame responding to a STA's request, so there is no need to modify a basic response rule, and an existing ML element may be utilized, but there is the need to define modification of a ML element for new indication information.

FIG. 21 is a diagram showing an additional example of an AP-related information request and response process according to the present disclosure.

STA 1 assumes a case in which information on a MLD (e.g., MLD 1) to which AP 1-a belongs and AP b belonging to a corresponding MLD is requested to AP 1-a (non-Tx BSSID) belonging to the same MBSSID set as AP 1 (Tx

BSSID) operating in link 1 (L1). In this case, AP 1-a may not transmit a probe response because it is a non-TX BSSID, and AP 1, a Tx BSSID, may transmit a probe response frame. A probe response frame may include a plurality of basic ML elements. A plurality of ML elements may have the same type/format/variant. A first basic ML element may include common information on a MLD (e.g., MLD 2) to which a Tx BSSID belongs. A second basic ML element may include common information on a MLD to which a non-Tx BSSID belongs (e.g., MLD 1), and link information on APs (e.g., AP 1-a and AP b) belonging to a corresponding MLD.

When at least one basic ML element exceeds 255 octets, AP 1 may apply a fragment to each corresponding ML element and transmit it to STA 1.

Embodiments described above are that elements and features of the present disclosure are combined in a predetermined form. Each element or feature should be considered to be optional unless otherwise explicitly mentioned. Each element or feature may be implemented in a form that it is not combined with other element or feature. In addition, an embodiment of the present disclosure may include combining a part of elements and/or features. An order of operations described in embodiments of the present disclosure may be changed. Some elements or features of one embodiment may be included in other embodiment or may be substituted with a corresponding element or a feature of other embodiment. It is clear that an embodiment may include combining claims without an explicit dependency relationship in claims or may be included as a new claim by amendment after application.

It is clear to a person skilled in the pertinent art that the present disclosure may be implemented in other specific form in a scope not going beyond an essential feature of the present disclosure. Accordingly, the above-described detailed description should not be restrictively construed in every aspect and should be considered to be illustrative. A scope of the present disclosure should be determined by reasonable construction of an attached claim and all changes within an equivalent scope of the present disclosure are included in a scope of the present disclosure.

A scope of the present disclosure includes software or machine-executable commands (e.g., an operating system, an application, a firmware, a program, etc.) which execute an operation according to a method of various embodiments in a device or a computer and a non-transitory computer-readable medium that such a software or a command, etc. are stored and are executable in a device or a computer. A command which may be used to program a processing system performing a feature described in the present disclosure may be stored in a storage medium or a computer-readable storage medium and a feature described in the present disclosure may be implemented by using a computer program product including such a storage medium. A storage medium may include a high-speed random-access memory such as DRAM, SRAM, DDR RAM or other random-access solid state memory device, but it is not limited thereto, and it may include a nonvolatile memory such as one or more magnetic disk storage devices, optical disk storage devices, flash memory devices or other non-volatile solid state storage devices. A memory optionally includes one or more storage devices positioned remotely from processor(s). A memory or alternatively, nonvolatile memory device(s) in a memory include a non-transitory computer-readable storage medium. A feature described in the present disclosure may be stored in any one of machine-readable mediums to control a hardware of a processing system and may be integrated into a software and/or a

35

firmware which allows a processing system to interact with other mechanism utilizing a result from an embodiment of the present disclosure. Such a software or a firmware may include an application code, a device driver, an operating system and an execution environment/container, but it is not limited thereto. 5

A method proposed by the present disclosure is mainly described based on an example applied to an IEEE 802.11-based system, 5G system, but may be applied to various WLAN or wireless communication systems other than the IEEE 802.11-based system. 10

What is claimed is:

1. A method performed by a non-access point multi-link device (non-AP MLD), the method comprising:
 - transmitting, by the non-AP MLD, a request frame including information indicating a first AP that is affiliated with a first AP MLD or information indicating the first AP MLD; and
 - receiving, by the non-AP MLD from a second AP, a response frame responding to the request frame, 15
 wherein the response frame includes a first multi-link (ML) element related to the first AP MLD and at least one AP affiliated with the first AP MLD, and
 - wherein the response frame also includes a second ML element related to a second AP MLD with which the second AP is affiliated. 20
2. The method of claim 1, wherein:
 - the first ML element included in the response frame includes information indicating that information on the first AP MLD is included in the first ML element. 25
3. The method of claim 2, wherein:
 - the first ML element is a first basic ML element, and the second ML element is a second basic ML element.
4. The method of claim 1, wherein:
 - the first AP is an AP corresponding to non-transmitted basic service set identification information (BSSID), 30
 - the second AP is an AP corresponding to transmitted BSSID.
5. The method of claim 4, wherein:
 - the first AP and the second AP are included in a same multiple BSSID (MBSSID) set. 35
6. The method of claim 1, wherein:
 - the information indicating the first AP is included in address information of the request frame, or
 - the information indicating a first AP MLD is included in AP MLD identification information of the request frame. 40
7. The method of claim 1, wherein:
 - the response frame includes a multiple BSSID element, the first ML element and the second ML element are included in a frame body of the response frame, and 45

36

locations of the first ML element and the second ML element are outside the multiple BSSID element.

8. The method of claim 1, wherein:
 - based on a size of the first ML element exceeding 255 octets, a fragment for the first ML element is generated,
 - based on a size of the second ML element exceeding 255 octets, a fragment for the second ML element is generated.
9. The method of claim 1, wherein:
 - the request frame is a probe request frame,
 - the response frame is a probe response frame.
10. A non-access point multi-link device (non-AP MLD) comprising:
 - at least one transceiver; and
 - at least one processor coupled with the at least one transceiver, 50
 wherein the at least one processor is configured to:
 - transmit, through the at least one transceiver, a request frame including information indicating a first AP that is affiliated with a first AP MLD or information indicating first AP MLD; and
 - receive, through the at least one transceiver, from a second AP, a response frame responding to the request frame,
 wherein the response frame includes a first multi-link (ML) element related to the first AP MLD and at least one AP affiliated with the first AP MLD, and
 - wherein the response frame also includes a second ML element related to a second AP MLD with which the second AP is affiliated.
11. A second access point (AP) affiliated with a second AP multi-link device (MLD), the second AP comprising:
 - at least one transceiver; and
 - at least one processor coupled with the at least one transceiver,
 wherein the at least one processor is configured to:
 - receive, through the at least one transceiver, from a non-AP MLD, a request frame including information indicating of a first AP that is affiliated with a first AP MLD or information indicating the first AP MLD; and
 - transmit, through the at least one transceiver, to the non-AP MLD, a response frame responding to the request frame,
 wherein the response frame includes a first multi-link (ML) element related to the first AP MLD and at least one AP affiliated with the first AP MLD, and
 - wherein the response frame also includes a second ML element related to the second AP MLD with which the second AP is affiliated.
