[0001] This non-provisional application claims priority from provisional application U.S. Ser. No. 60/355,302 filed Feb. 8, 2002.

**FIELD OF THE INVENTION**

[0002] The present invention relates to novel (oxime)carbamoyl derivatives and pharmaceutical compositions comprising said derivatives which inhibit fatty acid amide hydrolase and are useful for the treatment of conditions which can be effected by inhibiting fatty acid amide hydrolase.

**BACKGROUND OF THE INVENTION**

[0003] Effective treatment of pain with current therapies is limited by adverse effects and a lack of efficacy against all components of pain.

[0004] Current research is aimed at understanding the molecular and physiological components of pain processing to develop more effective analgesics (Levine, J. D., *New Directions in Pain Research: Meeting Report Molecules to Maladies*, *Neuron* 20: 649-654, 1998; Pasternak, G. W., *The Central Questions in Pain Perception May Be Peripheral*, *PNAS* 95:10354-10355, 1998).

[0005] The analgesic properties of cannabinoids have been known for many years and to many cultures. Cannabinoids are active in many pre-clinical models of pain, including neuropathic pain. Within the last few years, several endogenous cannabinoids, including the fatty acid amides arachidonylethanolamide (anandamide), and arachidonyl amino acids such as N-arachidonylglycine, homo- $\gamma$ -linolenyl-ethanolamide and docosatetraenyl-ethanolamide, as well as 2-arachidonyl-glycerol, have been shown to induce analgesia in laboratory animals (DeVane, W. A. et al., *Isolation and Structure of a Brain Constituent That Binds to the Cannabinoid Receptors*, *Science* 258:1946-1949, 1992; Hanus, L. et al., *Two New Unsaturated Fatty Acid Ethanolamides in Brain that Bind to the Cannabinoid Receptor*, *J. Med. Chem.* 36: 3032-3034, 1993; Machoulam, R. et al., *Identification of an Endogenous 2-Monoglyceride, Present in Canine Gut, That Binds To Cannabinoid Receptors*, *Biochem. Pharmacol.* 50: 83-90, 1995; Vogel, Z. et al., *Cannabinomimetic Behavioral Effects of and Adenylate Cyclase Inhibition By Two New Endogenous Anandamides*, *Eur. J. Pharmacol.* 287: 145-152, 1995; Hargreaves, K. M. et al., *Cannabinoids Reduce Hyperalgesia and Inflammation Via Interaction With Peripheral CB1 Receptors*, *Pain* 75: 111-119, 1998; Rice, A. S. C., et al., *The Anti-Hyperalgesic Actions of the Cannabinoid Anandamide and the Putative CB2 Receptor Agonist Palmitoylethanolamide in Visceral and Somatic Inflammatory Pain*, *Pain* 76:189-199, 1998; Huang, S. M., et al., *Identification of a New Class of Molecules, the Arachidonyl Amino Acids, and Characterization of One Member That Inhibits Pain*, *J. Biological Chemistry*, 276: 46, 42639-42644, 2001). The ability of cannabinoid receptor antagonists and cannabinoid receptor antisense to induce hyperalgesia in animals suggests that endogenous cannabinoids regulate the nociceptive threshold

(Hargreaves, K. M. et al., *Hypoactivity of the Spinal Cannabinoid System Results in NMDA-Dependent Hyperalgesia*, *J. Neurosci.* 18: 451-457, 1998; Piomelli, D. et al., *Control of Pain Initiation By Endogenous Cannabinoids*, *Nature* 394: 277-281, 1998; Fields, H. L. et al., *An Analgesia Circuit Activated By Cannabinoids*, *Nature* 395: 381-383, 1998). Elevation of levels of neuroactive fatty acid amides such as anandamide may provide a unique mechanism to achieve analgesia. The mechanisms by which endogenous cannabinoids are synthesized are not well understood; therefore, targets for drugs aimed at increasing the synthesis of these compounds are slow to be identified.

[0006] Anandamide and the other identified endogenous cannabinoids are inactivated through a cleavage mechanism by a membrane-bound enzyme, fatty acid amide hydrolase (FAAH). FAAH, therefore, provides an important target for regulating the activity of endogenous cannabinoids. The inhibition of FAAH may elevate levels of anandamide or other endogenous cannabinoids to increase the nociceptive threshold. Furthermore, the inhibition of FAAH would also extend the therapeutic benefits of other cannabinoid agonists in the treatment of emesis, anxiety, feeding behaviors, movement disorders, glaucoma, neuroprotection and cardiovascular disease.

[0198] R<sup>2</sup> is preferably hydrogen or methyl, and R<sup>3</sup> is preferably methyl, or phenyl optionally substituted with one or more halo, haloalkyl or nitro.

[0199] When B is represented by Formula IV:

[0200] X is preferably CH, R<sup>4</sup> is preferably halo, and b is 1. When X is nitrogen, however, b is preferably 0.

[0201] When B is represented by Formula V:

[0202] X is preferably nitrogen.

[0203] The description of the invention herein should be construed in congruity with the laws and principals of chemical bonding. For example, when a moiety is optionally substituted and said substitution requires the removal of a hydrogen atom from the moiety to be substituted, the description of the moiety should be read to include the moiety with or without said hydrogen atom. As another example, if a variable is defined as a particular moiety or atom and is further defined to have value of 0 or some integer, the bond(s) attaching said moiety should be suitably removed in the event the variable equals 0.

[0204] An embodiment or aspect which depends from another embodiment or aspect, will describe only the variables having values and provisos that differ from the embodiment or aspect from which it depends. For example, if a dependent embodiment describes a variable as being "phenyl or pyridyl", wherein said phenyl and pyridyl were described in the independent embodiment as being "optionally substituted", then the phenyl and pyridyl of the dependent embodiment will also be optionally substituted.

[0205] It is to be understood that the present invention may include any and all possible stereoisomers, geometric isomers, diastereoisomers, enantiomers, anomers and optical isomers, unless a particular description specifies otherwise. More particularly, the groups attached to the oxime portion of compounds of Formula (I), i.e., N=C, may assume transoid or cisoid configurations.

[0206] As used herein, "halo" or "halogen" includes fluoro, chloro, bromo and iodo. As used herein, "alkyl" or "alkylene" includes straight or branched chain configurations.

[0207] The compounds of this invention can exist in the form of pharmaceutically acceptable salts. Such salts include addition salts with inorganic acids such as, for example, hydrochloric acid and sulfuric acid, and with organic acids such as, for example, acetic acid, citric acid, methanesulfonic acid, toluenesulfonic acid, tartaric acid and maleic acid. Further, in case the compounds of this invention contain an acidic group, the acidic group can exist in the form of alkali metal salts such as, for example, a potassium salt and a sodium salt; alkaline earth metal salts such as, for example, a magnesium salt and a calcium salt; and salts with organic bases such as a triethylammonium salt and an arginine salt. The compounds of the present invention may be hydrated or non-hydrated.

[0208] The compounds of this invention can be administered in such oral dosage forms as tablets, capsules (each of which includes sustained release or timed release formulations), pills, powders, granules, elixirs, tinctures, suspensions, syrups and emulsions. The compounds of this invention may also be administered intravenously, intraperitoneally, subcutaneously, or intramuscularly, all using dosage forms well known to those skilled in the pharmaceutical arts. The compounds can be administered alone, but generally will be administered with a pharmaceutical carrier selected upon the basis of the chosen route of administration and standard pharmaceutical practice. Compounds of this invention can also be administered in intranasal form by topical use of suitable intranasal vehicles, or by transdermal routes, using transdermal skin patches. When compounds of this invention are administered transdermally the dosage will be continuous throughout the dosage regimen.

[0209] The dosage and dosage regimen and scheduling of a compounds of the present invention must in each case be carefully adjusted, utilizing sound professional judgment and considering the age, weight and condition of the recipient, the route of administration and the nature and extent of the disease condition. In accordance with good clinical practice, it is preferred to administer the instant compounds at a concentration level that will produce effective beneficial effects without causing any harmful or untoward side effects.

## EXAMPLE 155

[0618]

[0619] (1Z)-N-[[[(4-butoxyphenyl)amino]carbonyl]oxy]ethanimidoyl chloride This compound was synthesized in accordance with the following literature references: Ivanov, Y. et al., Anticholinesterase activity of O-carbamoylated acylhydroxymoyl chlorides, *Khim-Farm Zh.*, 26:5, 62-63, 1992; and Sakamoto, T. et al., A new synthesis of nitriles from N-alkoxyimidoyl halides with zinc, *Synthesis*, 9: 750-752, 1991.

[0620] Biological Data:

[0621] Homogenates of crude membranes were prepared from H4 cells that express transfected human FAAH (H4-FAAH cells). Briefly, cells were grown in DMEM supplemented with 10% FBS and Geneticin at a final concentration of 500  $\mu\text{g/ml}$  (Gibco BRL, Rockville, Md.). Confluent cultures of H4-FAAH cells were rinsed twice with phosphate-buffered saline [138 mM NaCl, 4.1 mM KCl, 5.1 mM  $\text{Na}_2\text{PO}_4$ , 1.5 mM  $\text{KH}_2\text{PO}_4$  (pH 7.5), 37° C.] and incubated for 5 to 10 minutes at 4° C. in lysis buffer [1 mM sodium bicarbonate]. Cells were transferred from plates to polypropylene tubes (16x100 mm), homogenized and centrifuged at 32,000xg for 30 minutes. Pellets were resuspended by homogenization in lysis buffer and centrifuged at 32,000xg for 30 minutes. Pellets were resuspended in lysis buffer (15-20  $\mu\text{g}$  protein/ml) then stored at -80° C. until needed. On the day of an experiment, membranes were diluted to 2.67  $\mu\text{g}$  protein/ml in 125 mM Tris-Cl, pH 9.0.

[0622] Activity of FAAH was measured using a modification of the method described by Omeir et al., 1995 (*Life Sci* 56:1999, 1995). Membrane homogenates (240 ng protein) were incubated at room temperature for one hour with 1.67 nM anandamide [ethanolamine 1- $^3\text{H}$ ] (available from American Radiolabeled Chemical Inc., St Louis, Mo.) and 10  $\mu\text{M}$  anandamide (available from Sigma/RBI, St. Louis, Mo.) in the absence and presence of inhibitors. The reaction was stopped by the addition of 1 volume of a solution of 1:1 methanol and dichloroethane. The mixture was shaken and then centrifuged at 1000xg for 15 minutes to separate the aqueous and organic phases. An aliquot of the aqueous phase, containing [ $^3\text{H}$ ]-ethanolamine was withdrawn and counted by scintillation spectroscopy. Data were expressed as the percentage of [ $^3\text{H}$ ]-ethanolamine formed versus vehicle, after subtraction of the background radioactivity determined in the presence of 10  $\mu\text{M}$  arachidonyl trifluoromethyl ketone (ATFMK), an inhibitor of FAAH.  $\text{IC}_{50}$  values were determined using a four-parameter logistic equation for dose-response curves. Compounds for which  $\text{IC}_{50}$  values are not provided herein showed no FAAH inhibition or marginal FAAH inhibition in preliminary tests.

**[0623]** The following pain models below utilized Example 5. CARRAGEENAN-INDUCED THERMAL HYPERALGESIA (Chronic Inflammatory Pain): Example 5 (40 mg/kg, i.p.) suppressed the development of thermal hyperalgesia induced by paw carrageenan. Paw carrageenan injection ( $\diamond$ , 0.45 Carr) produced strong thermal hyperalgesia as evidenced by the short escape latencies seen in vehicle treated rats ( $\diamond$ , 2:15 hr, Carr) as compared to the long baseline latencies (0:00 hr). Animals pretreated with Example 5 (#1, 0:15 hr) failed to exhibit hyperalgesic responses (compare  $\diamond$  to  $\blacksquare$  at 2:15 hr) and instead the latencies for drug treated animals were comparable to baseline. By 120 min post-carrageenan (2:45 hr), partial development of hyperalgesia was observed, that was reversed by a second injection of Example 5 (#2, 3:00 hr) which maintained thermal escape responses at basal levels for another hour (3:00-4:00 hr). No side effects were observed at 40 mg/kg, i.p. in drug ( $\blacksquare$ ) or vehicle ( $\diamond$ ) treated controls (CEW=Cremophor:Ethanol:Water 10:10:80, 2 ml/kg). Data are mean  $\pm$  s.e.m. (n=8 per group). \* p<0.05, \*\* p<0.01 Tukey's HSD, compared to vehicle. The results are shown in Table II below.

[0624] HARGREAVES TEST (Acute Thermal Pain)  
Example 5 (10 & 30 mg/kg; 2 ml/kg; i.v. hand infusion)  
produced a significant reversal of acute thermal pain behavior at 15 min post injection, which did not persist beyond this time. No significant side effects were observed at 10 mg/kg.

However, at 30 mg/kg side effects included strong sedation, reduced activity and splayed hindlimbs. Data are mean  $\pm$  s.e.m. (n=8 per group). \*\* p<0.01 Dunnett's Test, compared to vehicle control. The results are shown in Table III below.

**[0625]** PAW EDEMA MODEL (Inflammation-induced Edema) The effects of Example 5 on carrageenan-induced edema were examined in a quantitative manner (plethysmometry). Injections of carrageenan (2% lambda) into the plantar aspect of both hind paws, resulted in an increase in combined total paw volume (swelling) measured 3 hours

post-injection. Example 5 inhibited swelling by 26% at 40 mg/kg (Ex. 5-40, ip administered at -30 min and +2hr relative to carrageenan) but showed no efficacy at 20 mg/kg (Ex. 5-20, ip). The reference agent dexamethasone (Dex, 1 mg/kg, ip) inhibited swelling by 70%. Table IV, below, summarizes the data.
