(60) Provisional application No. 61/974,304, filed on Apr. 2, 2014.

Various embodiments of the present invention relate to a method for welding a workpiece comprising the steps of: making a first weld at a first position on said workpiece with a high energy beam, deflecting the high energy beam with at least one deflection lens for making a second weld at a second position on said workpiece, focusing the high energy beam on said workpiece with at least one focusing lens, shaping the high energy beam on said workpiece with at least one astigmatism lens so that the shape of the high energy beam on said workpiece is longer in a direction parallel to a deflection direction of said high energy beam than in a direction perpendicular to said deflection direction of said high energy beam. The invention is also related to the use of an astigmatism lens and to a method for forming a three dimensional article.

## METHOD FOR FUSING A WORKPIECE

### CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims priority to and the benefit of U.S. Provisional Patent Application Ser. No. 61/974,304, filed Apr. 2, 2014, the contents of which as are hereby incorporated by reference in their entirety.

### BACKGROUND

[0002] 1. Related Field

[0003] Various embodiments of the present invention relates to a method for welding a workpiece and a method for forming a three-dimensional article.

[0004] 2. Description of Related Art

[0005] Freeform fabrication or additive manufacturing is a method for forming three-dimensional articles through successive fusion of chosen parts of powder layers applied to a worktable. A method and apparatus according to this technique is disclosed in US 2009/0152771.

[0006] Such an apparatus may comprise a work table on which the three-dimensional article is to be formed, a powder dispenser, arranged to lay down a thin layer of powder on the work table for the formation of a powder bed, a ray gun for delivering energy to the powder whereby fusion of the powder takes place, elements for control of the ray given off by the ray gun over the powder bed for the formation of a cross section of the three-dimensional article through fusion of parts of the powder bed, and a controlling computer, in which information is stored concerning consecutive cross sections of the three-dimensional article. A three-dimensional article is formed through consecutive fusions of consecutively formed cross sections of powder layers, successively laid down by the powder dispenser.

[0007] There is always a demand for decreasing or minimizing the time for fusing powder material in additive manufacturing or when welding pieces together. One way to increase the efficiency and the speed in AM or when welding in general is to increase the power of the energy beam and at the same time increase the speed of deflection of said energy beam. The deposited power per surface unit can thereby be kept constant but being distributed faster over the surface which is to be fused or welded. However, this only works until a predetermined power and speed of deflection of said energy beam. If increasing the power over a predetermined value, the speed of deflection will be too fast so that the heat from the energy beam will not have sufficient time to penetrate into the material to be fused or welded. With a too high power and thereby a too fast speed of deflection of said energy beam, the surface temperature will become too high so that the material which is to be fused or welded is instead evaporated.

[0008] There is a need in the art to beyond that predetermined power and speed of deflection in welding and without evaporating the material which is to be fused or welded.

### BRIEF SUMMARY

[0009] Having this background, an object of the invention is to provide a method for welding or additive manufacturing with improved efficiency. The above-mentioned object is achieved by the features according to the claims contained herein.

[0010] According to various embodiments, a method for welding a workpiece is provided. The method comprising the

steps of: making a first weld at a first position on said workpiece with a high energy beam, deflecting the high energy beam with at least one deflection lens for making a second weld at a second position on said workpiece, focusing the high energy beam on said workpiece with at least one focusing lens, shaping the high energy beam on said workpiece with at least one astigmatism lens so that the shape of the high energy beam on said workpiece is longer in a direction parallel to a deflection direction of said high energy beam than in a direction perpendicular to said deflection direction of said high energy beam, wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is varying as a function of the power of said energy beam on said workpiece.

[0011] An advantage of the present invention is that the beam power may be increased substantially or very substantially, as one increases the astigmatism and the scan speed while still fusing the powder or welding the pieces together to a sufficient depth while avoiding evaporation due to excessive temperatures. This may also result in decreased building time. Another advantage of the present invention is that the fusing accuracy or melt width perpendicular to the scanning direction may be kept constant irrespective of the used beam power and scan speed.

[0012] In an example embodiment of the present invention said energy beam is a laser beam or an electron beam. A non-limiting advantage of at least this embodiment is that the invention is independent of the energy beam source used.

[0013] In still another example embodiment of the present invention a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction may also be varied as a function of the position of said high energy beam on said workpiece. A non-limiting advantage of at least this embodiment is that the protraction of the beam spot may not only be beam power dependent but may also be depending on the pattern which is to be fused.

[0014] According to another aspect of the present invention it is provided a method of using an astigmatism lens in additive manufacturing for forming a three-dimensional article through successive fusion, with a high energy beam, of parts of at least one layer of a powder bed provided on a work table, which parts correspond to successive cross sections of the three dimensional article, said astigmatism lens may be used for prolonging the size the high energy beam on said layer of powder bed in a direction parallel to a deflection direction more than in a direction perpendicular to said deflection direction, wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is varying as a function of the power of said energy beam on said workpiece.

[0015] A non-limiting advantage of at least this embodiment is that the method of using the astigmatism lens may be widened from the normal use where the beam spot shape is corrected back to its original shape due to distortions introduced in the lens system between the energy beam source and the target surface. According to the present invention the astigmatism lens system, which may be a true lens system in case of a laser beam and an electrical coil system in case of an electron beam, may be used for shaping the beam so as to protract the beam size in a direction parallel to the deflection direction giving a beam shape which is longer in a direction parallel to the scanning direction compared to a direction

perpendicular to said scanning direction. The degree of said protraction is at least varying as a function of the power of said energy beam.

**[0016]** In still another aspect of the present invention it is provided a method for forming a three-dimensional article through successively depositing individual layers of powder material that are fused together so as to form the article, said method comprising the steps of: providing at least one high energy beam source for emitting a high energy beam for at least one of heating or fusing said powder material, providing a deflection source for deflecting the high energy beam on said powder material, providing a focus lens for focusing said high energy beam on said powder material, shaping the high energy beam on said powder layer with at least one astigmatism lens so that the shape of the high energy beam on said layer of powder is longer in a direction parallel to a deflection direction of said high energy beam than in a direction perpendicular to said deflection direction of said high energy beam, wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is varying as a function of the power of said energy beam on said workpiece.

**[0017]** A non-limiting advantage of various embodiments of the present invention is that the power may be increased substantially or very substantially, the more power the more astigmatism and faster scan speed. This also results in decreased building time for additively manufactured parts. Another advantage of the present invention is that the fusing accuracy or melt width perpendicular to the scanning direction may be kept constant irrespective of the used beam power and scan speed, meaning that the accuracy is not affected when decreasing the building time for additively manufactured parts according to the present invention.

**[0018]** In an example embodiment of the present invention said energy beam is a laser beam or an electron beam. A non-limiting advantage of at least this embodiment is that the invention is independent of the energy beam source used.

**[0019]** In still another example embodiment of the present invention a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is also varying as a function of the position of said high energy beam on said workpiece. A non-limiting advantage of at least this embodiment is that the protraction of the beam spot is not only beam power dependent but also depending on the pattern which is to be fused.

**[0020]** In yet another example embodiment of the present invention a mean spot size on said workpiece in a direction perpendicular to the scanning direction is smaller than a mean spot size on said workpiece in a direction parallel to the scanning direction for a full scan length, a full cross section and/or for a full 3-dimensional article. A non-limiting advantage of at least this embodiment is that one may choose for which part of the build the mean spot size in a direction parallel to the scanning direction is longer than the mean spot size in a direction perpendicular to the scanning direction.

**[0021]** In yet another example embodiment of the present invention, any of the described methods may be performed, at least in part via execution of one or more computer processors.

**[0022]** In yet another example embodiment of the present invention, an apparatus is provided for forming a three-dimensional article through successively depositing individual layers of powder material that are fused together so as to form the article. The apparatus comprises: at least one high energy

beam source for emitting a high energy beam for at least one of heating or fusing said powder material; a deflection source for deflecting the high energy beam on said powder material; a focus lens for focusing said high energy beam on said powder material; at least one astigmatism lens; and at least one controller configured to control said at least one astigmatism lens so as to shape the high energy beam on said powder layer such that the shape of the high energy beam on said layer of powder is longer in a direction parallel to a deflection direction of said high energy beam than in a direction perpendicular to said deflection direction of said high energy beam, wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is varying as a function of the power of said energy beam on said workpiece.

**[0023]** In yet another example embodiment of the present invention an apparatus for welding a workpiece is provided. The apparatus comprises in certain embodiments: a high energy beam configured to make a first weld at a first position on said workpiece; at least one deflection lens configured to deflect the high energy beam so as to cause the high energy beam to make a second weld at a second position on said workpiece; at least one focusing lens configured to focus the high energy beam on said workpiece; and at least one astigmatism lens; and at least one controller configured to: shape the high energy beam on said workpiece with said at least one astigmatism lens so that the shape of the high energy beam on said workpiece is longer in a direction parallel to a deflection direction of said high energy beam than in a direction perpendicular to said deflection direction of said high energy beam, wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is varying as a function of the power of said energy beam on said workpiece.

**[0024]** In yet another example embodiment of the present invention a computer program product for forming a three-dimensional article through successively depositing individual layers of powder material that are fused together so as to form the article is provided. The computer program product comprises at least one non-transitory computer-readable storage medium having computer-readable program code portions stored therein. The computer-readable program code portions comprise: an executable portion configured to provide at least one high energy beam source for emitting a high energy beam for at least one of heating or fusing said powder material; an executable portion configured to provide a deflection source for deflecting the high energy beam on said powder material; an executable portion configured to provide a focus lens for focusing said high energy beam on said powder material; and an executable portion configured to shape the high energy beam on said powder layer with at least one astigmatism lens so that the shape of the high energy beam on said layer of powder is longer in a direction parallel to a deflection direction of said high energy beam than in a direction perpendicular to said deflection direction of said high energy beam, wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is varying as a function of the power of said energy beam on said workpiece.

**[0025]** In yet another example embodiment of the present invention a computer program product for welding a workpiece is provided. The computer program product comprises at least one non-transitory computer-readable storage medium having computer-readable program code portions

stored therein. The computer-readable program code portions comprise: an executable portion configured to make a first weld at a first position on said workpiece with a high energy beam; an executable portion configured to deflect the high energy beam with at least one deflection lens for making a second weld at a second position on said workpiece; an executable portion configured to focus the high energy beam on said workpiece with at least one focusing lens; and an executable portion configured to shape the high energy beam on said workpiece with at least one astigmatism lens so that the shape of the high energy beam on said workpiece is longer in a direction parallel to a deflection direction of said high energy beam than in a direction perpendicular to said deflection direction of said high energy beam, wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is varying as a function of the power of said energy beam on said workpiece.

#### BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

[0026] Having thus described the invention in general terms, reference will now be made to the accompanying drawings, which are not necessarily drawn to scale, and wherein:

[0027] FIG. 1 depicts a schematic graph of a beam power as a function of scan speed;

[0028] FIG. 2 depicts a view from above of an additive manufacturing process with an enlarged view of the beam spot configuration;

[0029] FIG. 3 depicts an example embodiment of a freeform fabrication or additive manufacturing apparatus in which the method may be implemented;

[0030] FIG. 4A depicts a beam spot configuration according to prior art;

[0031] FIG. 4B depicts an example embodiment of a beam spot configuration according to the present invention;

[0032] FIG. 5A-5C depicts three different beam spot configurations for different beam power;

[0033] FIG. 6 depicts an example embodiment for accomplishing an appropriate beam spot shape in a laser beam based system,

[0034] FIG. 7 depicts an example embodiment for accomplishing an appropriate beam spot shape in an electron beam based system, and

[0035] FIG. 8 depicts a schematic flow chart of a method according to the present invention.

[0036] FIG. 9 is a block diagram of an exemplary system 1020 according to various embodiments;

[0037] FIG. 10A is a schematic block diagram of a server 1200 according to various embodiments; and

[0038] FIG. 10B is a schematic block diagram of an exemplary mobile device 1300 according to various embodiments.

#### DETAILED DESCRIPTION OF VARIOUS EMBODIMENTS

[0039] Various embodiments of the present invention will now be described more fully hereinafter with reference to the accompanying drawings, in which some, but not all embodiments of the invention are shown. Indeed, embodiments of the invention may be embodied in many different forms and should not be construed as limited to the embodiments set forth herein. Rather, these embodiments are provided so that this disclosure will satisfy applicable legal requirements.

Unless otherwise defined, all technical and scientific terms used herein have the same meaning as commonly known and understood by one of ordinary skill in the art to which the invention relates. The term “or” is used herein in both the alternative and conjunctive sense, unless otherwise indicated. Like numbers refer to like elements throughout.

[0040] Still further, to facilitate the understanding of this invention, a number of terms are defined below. Terms defined herein have meanings as commonly understood by a person of ordinary skill in the areas relevant to the present invention. Terms such as “a”, “an” and “the” are not intended to refer to only a singular entity, but include the general class of which a specific example may be used for illustration. The terminology herein is used to describe specific embodiments of the invention, but their usage does not delimit the invention, except as outlined in the claims.

[0041] The term “three-dimensional structures” and the like as used herein refer generally to intended or actually fabricated three-dimensional configurations (e.g., of structural material or materials) that are intended to be used for a particular purpose. Such structures, etc. may, for example, be designed with the aid of a three-dimensional CAD system.

[0042] The term “electron beam” as used herein in various embodiments refers to any charged particle beam. The sources of charged particle beam can include an electron gun, a linear accelerator and so on.

[0043] FIG. 3 depicts an embodiment of a freeform fabrication or additive manufacturing apparatus 300 in which the present method may be implemented. The apparatus 300 comprising an electron gun 302; two powder hoppers 306, 307; a start plate 316; a build tank 312; a powder distributor 310; a build platform 314; beam managing optics 305; and a vacuum chamber 320.

[0044] The vacuum chamber 320 is capable of maintaining a vacuum environment by means of a vacuum system, which system may comprise a turbo-molecular pump, a scroll pump, an ion pump and one or more valves which are well known to a skilled person in the art and therefore need no further explanation in this context. The vacuum system is controlled by a control unit 340.

[0045] The electron gun 302 is generating an electron beam which is used for melting or fusing together powder material 318 provided on the start plate 316. The electron gun 302 may be provided in or in connection to the vacuum chamber 320. The control unit 340 may be used for controlling and managing the electron beam emitted from the electron beam gun 302. The beam managing optics may comprise at least one focusing coil, at least one deflection coil and at least one astigmatism coil which may be electrically connected to the control unit 340. In an example embodiment of the invention the electron gun may generate a focusable electron beam with an accelerating voltage of about 60 kV and with a beam power in the range of 0-10 kW. The pressure in the vacuum chamber may be in the range of  $1 \times 10^{-3}$ - $1 \times 10^{-6}$  mBar when building the three-dimensional article by fusing the powder layer by layer with the energy beam.

[0046] Instead of using one or a plurality of electron beam sources one or a plurality of laser beam sources may be used for generating one or a plurality of laser beams for melting the powder material or for welding pieces together according to the present invention.

[0047] The powder hoppers 306, 307 comprise the powder material to be provided on the start plate 316 in the build tank 312. The powder material may for instance be pure metals or

metal alloys such as titanium, titanium alloys, aluminum, aluminum alloys, stainless steel, Co—Cr—W alloy, etc. Instead of using two powder hoppers one powder hopper may be used. In another example embodiment another known type of powder feed and/or powder storage may be used.

[0048] The powder distributor **310** is arranged to lay down a thin layer of the powder material on the start plate **316**. During a work cycle the build platform **314** will be lowered successively in relation to the ray gun, electron beam based or laser beam based, after each added layer of powder material. In order to make this movement possible, the build platform **314** is in one embodiment of the invention arranged movably in vertical direction, i.e., in the direction indicated by arrow P. This means that the build platform **314** starts in an initial position, in which a first powder material layer of necessary thickness has been laid down on the start plate **316**. The build platform is thereafter lowered in connection with laying down a new powder material layer for the formation of a new cross section of a three-dimensional article. Means for lowering the build platform **314** may for instance be through a servo engine equipped with a gear, adjusting screws etc.

[0049] A three-dimensional article which is formed through successive fusion of parts of a powder bed, which parts corresponds to successive cross sections of the three-dimensional article, comprising a step of providing a model of the three dimensional article. The model may be generated via a CAD (Computer Aided Design) tool.

[0050] A first powder layer may be provided on the work table **316** by distributing powder evenly over the worktable according to several methods. One way to distribute the powder is to collect material fallen down from the hopper **306**, **307** by a rake system. The rake is moved over the build tank thereby distributing the powder over the start plate. The distance between a lower part of the rake and the upper part of the start plate or previous powder layer determines the thickness of powder distributed over the start plate. The powder layer thickness can easily be adjusted by adjusting the height of the build platform **314**.

[0051] An energy beam is directed over the work table **316** causing the first powder layer to fuse in selected locations to form a first cross section of the three-dimensional article. The energy beam may be an electron beam or a laser beam. The beam is directed over the work table **316** from instructions given by a control unit **340**. In the control unit instructions for how to control the beam gun for each layer of the three-dimensional article is stored.

[0052] After a first layer is finished, i.e., the fusion of powder material for making a first layer of the three-dimensional article, a second powder layer is provided on the work table **316**. The second powder layer is preferably distributed according to the same manner as the previous layer. A powder distributor in the form of a single rake system, i.e., where one rake is catching powder fallen down from both a left powder hopper **306** and a right powder hopper **307**, the rake as such can change design.

[0053] After having distributed the second powder layer on the work table **316**, the energy beam is directed over the work table causing the second powder layer to fuse in selected locations to form a second cross section of the three-dimensional article. Fused portions in the second layer may be bonded to fused portions of the first layer. The fused portions in the first and second layer may be melted together by melt-

ing not only the powder in the uppermost layer but also remelting at least a fraction of a thickness of a layer directly below the uppermost layer.

[0054] FIG. 1 depicts a schematic graph **175** of a beam power as a function of scan speed. For beam power lower than a predetermined value an essentially circular beam spot may be used for fusing powder material or for welding pieces together. If increasing the beam power over a predetermined value, and thereby increasing the scan speed over a predetermined value, the material will start to boil instead of melt. The reason for this boiling of material is that the deflection or scan speed of the energy beam will be too fast so that the heat from the energy beam will not have sufficient time to penetrate into the material to be fused or welded. With a too high power and thereby a too fast speed of deflection of said energy beam, the surface temperature will become too high so that the material which is to be fused or welded is instead evaporated.

[0055] The invention solves this problem by protracting the spot, i.e., extending the spot dimension parallel to the scan direction and essentially keeping its dimension perpendicular to the scan direction. In FIG. 1 an essentially circular spot may be used for beam power and scan speed below P1 and S1 respectively. For beam power and scan speed above P1 and S1 respectively the beam spot is protracted in the direction parallel to the scan direction. By letting the beam spot being protracted parallel to the scan direction the surface temperature may be decreased since the power in said beam is distributed over a larger area. The heat from the beam spot may, because of this beam power distribution over a larger area, have sufficient time to penetrate into the material and thereby minimizing the radiated energy from the melt pool and thereby minimizing the boiling or evaporation of material. By protracting the beam spot in parallel to the scan direction, larger beam powers may be used compared to if a circular spot would have been used with a maintained resolution of the fusing or welding. The protracted beam spot may follow an intended scanning path so that the longer dimension of said beam spot follows the beam path, i.e., the dimension perpendicular to the scanning direction is smaller than the dimension parallel to the scanning direction irrespective of the direction of the intended beam path.

[0056] FIG. 2 depicts a view from above of an additive manufacturing process with an enlarged view **200** of the beam spot configuration. In FIG. 2 a cross section **270** of a three dimensional article is being built by melting powder material inside a build chamber **290** with an energy beam **210**. The energy beam **210** is melting the material according to predetermined instructions stored in a control unit. The scan direction in FIG. 2 is denoted by an arrow **240**. A number of scan lines **250** have already been provided onto the powder material in order to build the cross section of the three dimensional article. One scan line **220** is being provided onto the powder material and an enlarged view **200** of the beam spot **230** illustrates that the actual length L of the beam spot **230** in parallel to the scan direction **240** is larger than the dimension of the beam spot **230** perpendicular to the scan direction denoted by H.

[0057] FIG. 4A illustrates a beam spot shape when using beam power lower than a predetermined value. In FIG. 4A the horizontal size L1 of the beam spot in parallel to the scan direction is essentially equal to the vertical size H1 of the beam spot perpendicular to the scan direction.

[0058] FIG. 4B illustrates a beam spot shape when using a beam power higher than said predetermined value. In FIG. 4B

the horizontal size **L2** of the beam spot in parallel to the scan direction is substantially larger than the vertical size **H1** of the beam spot perpendicular to the scan direction. As can be seen the vertical size **H1** of the beam spot perpendicular to the scan direction is equal in FIGS. 4A and 4B. Any scan direction may be used, i.e. not only the horizontal scan direction as have been illustrated in the figures. The beam spot size for beam powers larger than a predetermined value may be larger in a direction in parallel to the scan direction than in a direction perpendicular to the scan direction for any scan direction.

[0059] FIG. 5A-5C depicts three different beam spot configurations for three different beam power. The first beam spot **510** in FIG. 5A has a first beam power. The second beam spot **520** in FIG. 5B has a second beam power which is higher than said first beam power. The third beam spot **530** in FIG. 5C has a third beam power which is higher than said second beam power. The first length **L3** of said first beam spot **510** is shorter than said second length **L4** of said second beam spot **520** which is shorter than the third length **L5** of said third beam spot **530**. The first, second and third beam spot have all the same size **H1** perpendicular to the scan direction. In FIG. 5A-5C the shape of the beam spot is illustrated to be elliptical. However, any protracted shape of the beam spot may be used such as rectangular or polygonal or any other suitable mathematical function where the size of the beam spot is protracted in the scanning direction compared to the size perpendicular to the scanning direction.

[0060] FIG. 6 depicts an example embodiment of beam management optics in a laser beam based system. A laser beam **605** is emanating from a laser beam source **610**. Before reaching a target surface **660** which may be a powder layer in a layer based additive manufacturing process or solid pieces which are about to be welded together, said laser beam **605** is passing through an astigmatism lens system **620**, a focusing lens system **630**, a deflection lens system **640**, and an optional reflective surface **650**. A control unit **680** may be controlling the laser beam source **610** and said lens systems **620**, **630**, **640**. The focusing lens **630** system may comprise one or a plurality of lenses which may be rotatable and/or tiltable and/or translatable (movable along the optical axis) with respect to an optical axis. The focusing lens system **630** may be creating a predetermined beam spot size on the target surface **660**. The lenses in the focusing lens system **630** may be fully or partially transparent. The deflection lens system **640** may comprise one or a plurality of lenses which may be rotatable and/or tiltable and/or translatable (movable along the optical axis) with respect to an optical axis. The deflection lens system **640** may position the beam spot at any predetermined position within given limitations, which are defined by the maximum deflection of the beam spot, at said target surface **660**.

[0061] The astigmatism lens system **620** may comprise one or a plurality of lenses which may be rotatable and/or tiltable and/or translatable (movable along the optical axis) with respect to an optical axis. When a beam is deflected certain aberrations is introduced into the beam spot which is depending on the degree of deflection. The beam is more or less distorted depending on the degree of deflection which may be compensated by the astigmatism lens system **620**. According to the present invention said beam spot may not only be compensated for distortions which may be introduced by the other lens systems, but said astigmatism lens system **620** may also intentionally distorting the beam spot shape so as to protract the beam spot in a direction parallel to the direction of

beam deflection. The degree of protraction in said direction parallel to said deflection direction may at least be depending on the beam power of said energy beam. In an example embodiment said beam spot shape is protracted parallel to said deflection direction as a linearly function of said beam power above a predetermined beam power. In another example embodiment said beam spot shape is protracted parallel to said deflection direction as a polynomial function of said beam power above a predetermined beam power.

[0062] FIG. 7 depicts an example embodiment of beam management optics in a electron beam based system. An electron beam **750** is emanating from an electron beam source **710**. Before reaching a target surface **760**, which may be a powder layer in a layer based additive manufacturing process or solid pieces which are about to be welded together, said electron beam **750** may be passing through a astigmatism lens system **720**, a focusing lens system **730**, an deflection lens system **740**. A control unit **680** may control the electron beam source and said beam shaping optics. The focusing lens system **730** may comprise one or a plurality of focusing coils. The focusing lens system **730** may create a predetermined beam spot size on the target surface **760**.

[0063] The deflection lens system **740** may comprise one or a plurality of deflection coils. The deflection lens system **740** may position the beam spot at any predetermined position within given limitations, which are defined by the maximum deflection of the beam spot, at said target surface **760**.

[0064] The astigmatism lens system **720** may comprise one or a plurality of astigmatism coils. When a beam is deflected certain aberrations is introduced into the beam spot which is depending on the degree of deflection. The beam may be more or less distorted depending on the degree of deflection which may be compensated by the astigmatism lens system **720**. According to the present invention said beam spot is not only compensated for distortions, which may be introduced by the other lens systems, but said astigmatism lens system **720** may also intentionally distort the beam spot shape so as to protract the beam spot in a direction parallel to the direction of beam deflection. The degree of protraction in said direction parallel to said deflection direction may at least be depending on the beam power of said energy beam. In an example embodiment said beam spot shape may be protracted parallel to said deflection direction as a linearly function of said beam power above a predetermined beam power. In another example embodiment said beam spot shape may be protracted parallel to said deflection direction as a polynomial function of said beam power above a predetermined beam power. In an example embodiment a plurality of astigmatism lenses may be used for generating an arbitrary orientation of said protracted beam in any position of the workpiece.

[0065] In a laser beam based and electron beam based system said protraction parallel to the deflection direction may not only depend on the power of said energy beam but also on the position on said target surface. More particularly said protraction of said energy beam may depend, in addition to said energy beam power, on the actual fusing or welding position of said energy beam spot on said target surface. In an additive manufacturing process, said protraction may depend on the actual position of said energy beam spot with respect to said pattern which is to be fused, i.e., a more protracted beam spot may be used in the middle section of a scan length compared to at the start or stop position of the scan line. If melting a contour the protraction may be altered during the melting of said contour depending on the derivate of the

contour and the distance to said contour derivate. In an example embodiment the protraction, power and scan speed of the beam spot on said workpiece may be chosen so as to optimize the build time.

**[0066]** FIG. 8 depicts a schematic flow chart of a method according to the present invention for welding a workpiece or for fusing together powder material according to a predetermined scheme for building a three dimensional article layer by layer. In a first step denoted **810** a first weld is made at a first position on said workpiece or powder surface with a high energy beam. In a second step denoted **820** the high energy beam is deflected with at least one deflection lens for making a second weld at a second position on said workpiece or said powder surface. In a third step denoted **830** the high energy beam is focused on said workpiece with at least one focusing lens. In a fourth step denoted **840** the high energy beam is shaped on said workpiece or powder surface with at least one astigmatism lens so that the shape of the high energy beam on said workpiece is longer in a direction parallel to a deflection direction of said high energy beam than in a direction perpendicular to said deflection direction of said high energy beam, wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is varying as a function of the power of said energy beam on said workpiece. An increased power of the beam spot on said workpiece will demand for higher scan speed of said beam spot on said workpiece.

**[0067]** The ratio of said length in said parallel direction and said length in said perpendicular direction with respect to said deflection direction of said energy beam may be one of a group of 5, 10, 15 or 20. In an example embodiment said length in said parallel direction and said perpendicular direction is essentially equal for beam power below a predetermined value which will not cause evaporation of the material to fuse with a predetermined weld or fusing width, since the speed and powder of said beam spot on said workpiece will not cause evaporation of the workpiece material.

**[0068]** In an example embodiment of the present invention a mean spot size on said workpiece in a direction perpendicular to the scanning direction is smaller than the mean spot size on said workpiece in a direction parallel to the scanning direction for a full scan length, a full cross section and/or for a full 3-dimensional article.

**[0069]** Fusing or welding with a protracted beam spot may have the effect of using higher beam spot power and higher beam scanning speed. A protracted beam spot may decrease the surface temperature for a given scanning speed compared with a circular spot having the same power and a diameter equal to the smaller dimension of the protracted beam spot. A protracted beam spot may allow for a higher scanning speed with preserved resolution in a direction perpendicular to the scanning direction compared with a circular spot having a diameter equal to the smaller dimension of the protracted beam spot. A protracted beam spot may allow for heat to penetrate into the material instead of evaporating the material as may be the case with a circular spot. A protracted beam spot may decrease the manufacturing time for an additively manufactured 3-dimensional article compared with a circular spot having the same power and a diameter equal to the smaller dimension of the protracted beam spot.

**[0070]** In another aspect of the invention it is provided a program element configured and arranged when executed on a computer to implement a method for forming at least one three-dimensional article through successive fusion of parts

of a powder bed, which parts correspond to successive cross sections of the three-dimensional article, the method comprising the steps of: providing a model of the at least one three-dimensional article; applying a first powder layer on a work table; directing a first energy beam from a first energy beam source over the work table so as to cause the first powder layer to fuse in first selected locations according to corresponding models so as to form a first cross section of the three-dimensional article, where the first energy beam is configured to fuse at least a first region of a first cross section with two or more parallel scan lines in a first direction; and determining a distance between two adjacent of the two or more parallel scan lines, which are used for fusing the powder layer, as a function of a length of at least one of the two adjacent scan lines. The program element may be installed in a computer readable storage medium. The computer readable storage medium may be any control unit as described elsewhere herein or another separate and distinct control unit. The computer readable storage medium and the program element, which may comprise computer-readable program code portions embodied therein, may further be contained within a non-transitory computer program product. Further details regarding these features and configurations are provided, in turn, below.

**[0071]** As mentioned, various embodiments of the present invention may be implemented in various ways, including as non-transitory computer program products. A computer program product may include a non-transitory computer-readable storage medium storing applications, programs, program modules, scripts, source code, program code, object code, byte code, compiled code, interpreted code, machine code, executable instructions, and/or the like (also referred to herein as executable instructions, instructions for execution, program code, and/or similar terms used herein interchangeably). Such non-transitory computer-readable storage media include all computer-readable media (including volatile and non-volatile media).

**[0072]** In one embodiment, a non-volatile computer-readable storage medium may include a floppy disk, flexible disk, hard disk, solid-state storage (SSS) (e.g., a solid state drive (SSD), solid state card (SSC), solid state module (SSM)), enterprise flash drive, magnetic tape, or any other non-transitory magnetic medium, and/or the like. A non-volatile computer-readable storage medium may also include a punch card, paper tape, optical mark sheet (or any other physical medium with patterns of holes or other optically recognizable indicia), compact disc read only memory (CD-ROM), compact disc compact disc-rewritable (CD-RW), digital versatile disc (DVD), Blu-ray disc (BD), any other non-transitory optical medium, and/or the like. Such a non-volatile computer-readable storage medium may also include read-only memory (ROM), programmable read-only memory (PROM), erasable programmable read-only memory (EPROM), electrically erasable programmable read-only memory (EEPROM), flash memory (e.g., Serial, NAND, NOR, and/or the like), multimedia memory cards (MMC), secure digital (SD) memory cards, SmartMedia cards, CompactFlash (CF) cards, Memory Sticks, and/or the like. Further, a non-volatile computer-readable storage medium may also include conductive-bridging random access memory (CBRAM), phase-change random access memory (PRAM), ferroelectric random-access memory (FeRAM), non-volatile random-access memory (NVRAM), magnetoresistive random-access memory (MRAM), resistive random-access memory

(RRAM), Silicon-Oxide-Nitride-Oxide-Silicon memory (SONOS), floating junction gate random access memory (FJG RAM), Millipede memory, racetrack memory, and/or the like.

**[0073]** In one embodiment, a volatile computer-readable storage medium may include random access memory (RAM), dynamic random access memory (DRAM), static random access memory (SRAM), fast page mode dynamic random access memory (FPM DRAM), extended data-out dynamic random access memory (EDO DRAM), synchronous dynamic random access memory (SDRAM), double data rate synchronous dynamic random access memory (DDR SDRAM), double data rate type two synchronous dynamic random access memory (DDR2 SDRAM), double data rate type three synchronous dynamic random access memory (DDR3 SDRAM), Rambus dynamic random access memory (RDRAM), Twin Transistor RAM (TTRAM), Thyristor RAM (T-RAM), Zero-capacitor (Z-RAM), Rambus in-line memory module (RIMM), dual in-line memory module (DIMM), single in-line memory module (SIMM), video random access memory VRAM, cache memory (including various levels), flash memory, register memory, and/or the like. It will be appreciated that where embodiments are described to use a computer-readable storage medium, other types of computer-readable storage media may be substituted for or used in addition to the computer-readable storage media described above.

**[0074]** As should be appreciated, various embodiments of the present invention may also be implemented as methods, apparatus, systems, computing devices, computing entities, and/or the like, as have been described elsewhere herein. As such, embodiments of the present invention may take the form of an apparatus, system, computing device, computing entity, and/or the like executing instructions stored on a computer-readable storage medium to perform certain steps or operations. However, embodiments of the present invention may also take the form of an entirely hardware embodiment performing certain steps or operations.

**[0075]** Various embodiments are described below with reference to block diagrams and flowchart illustrations of apparatuses, methods, systems, and computer program products. It should be understood that each block of any of the block diagrams and flowchart illustrations, respectively, may be implemented in part by computer program instructions, e.g., as logical steps or operations executing on a processor in a computing system. These computer program instructions may be loaded onto a computer, such as a special purpose computer or other programmable data processing apparatus to produce a specifically-configured machine, such that the instructions which execute on the computer or other programmable data processing apparatus implement the functions specified in the flowchart block or blocks.

**[0076]** These computer program instructions may also be stored in a computer-readable memory that can direct a computer or other programmable data processing apparatus to function in a particular manner, such that the instructions stored in the computer-readable memory produce an article of manufacture including computer-readable instructions for implementing the functionality specified in the flowchart block or blocks. The computer program instructions may also be loaded onto a computer or other programmable data processing apparatus to cause a series of operational steps to be performed on the computer or other programmable apparatus to produce a computer-implemented process such that the

instructions that execute on the computer or other programmable apparatus provide operations for implementing the functions specified in the flowchart block or blocks.

**[0077]** Accordingly, blocks of the block diagrams and flowchart illustrations support various combinations for performing the specified functions, combinations of operations for performing the specified functions and program instructions for performing the specified functions. It should also be understood that each block of the block diagrams and flowchart illustrations, and combinations of blocks in the block diagrams and flowchart illustrations, could be implemented by special purpose hardware-based computer systems that perform the specified functions or operations, or combinations of special purpose hardware and computer instructions.

**[0078]** FIG. 9 is a block diagram of an exemplary system 1020 that can be used in conjunction with various embodiments of the present invention. In at least the illustrated embodiment, the system 1020 may include one or more central computing devices 1110, one or more distributed computing devices 1120, and one or more distributed handheld or mobile devices 1300, all configured in communication with a central server 1200 (or control unit) via one or more networks 1130. While FIG. 9 illustrates the various system entities as separate, standalone entities, the various embodiments are not limited to this particular architecture.

**[0079]** According to various embodiments of the present invention, the one or more networks 1130 may be capable of supporting communication in accordance with any one or more of a number of second-generation (2G), 2.5G, third-generation (3G), and/or fourth-generation (4G) mobile communication protocols, or the like. More particularly, the one or more networks 1130 may be capable of supporting communication in accordance with 2G wireless communication protocols IS-136 (TDMA), GSM, and IS-95 (CDMA). Also, for example, the one or more networks 1130 may be capable of supporting communication in accordance with 2.5G wireless communication protocols GPRS, Enhanced Data GSM Environment (EDGE), or the like. In addition, for example, the one or more networks 1130 may be capable of supporting communication in accordance with 3G wireless communication protocols such as Universal Mobile Telephone System (UMTS) network employing Wideband Code Division Multiple Access (WCDMA) radio access technology. Some narrow-band AMPS (NAMPS), as well as TACS, network(s) may also benefit from embodiments of the present invention, as should dual or higher mode mobile stations (e.g., digital/analog or TDMA/CDMA/analog phones). As yet another example, each of the components of the system 1020 may be configured to communicate with one another in accordance with techniques such as, for example, radio frequency (RF), Bluetooth™, infrared (IrDA), or any of a number of different wired or wireless networking techniques, including a wired or wireless Personal Area Network (“PAN”), Local Area Network (“LAN”), Metropolitan Area Network (“MAN”), Wide Area Network (“WAN”), or the like.

**[0080]** Although the device(s) 1110-1300 are illustrated in FIG. 9 as communicating with one another over the same network 1130, these devices may likewise communicate over multiple, separate networks.

**[0081]** According to one embodiment, in addition to receiving data from the server 1200, the distributed devices 1110, 1120, and/or 1300 may be further configured to collect and transmit data on their own. In various embodiments, the devices 1110, 1120, and/or 1300 may be capable of receiving

data via one or more input units or devices, such as a keypad, touchpad, barcode scanner, radio frequency identification (RFID) reader, interface card (e.g., modem, etc.) or receiver. The devices **1110**, **1120**, and/or **1300** may further be capable of storing data to one or more volatile or non-volatile memory modules, and outputting the data via one or more output units or devices, for example, by displaying data to the user operating the device, or by transmitting data, for example over the one or more networks **1130**.

[0082] In various embodiments, the server **1200** includes various systems for performing one or more functions in accordance with various embodiments of the present invention, including those more particularly shown and described herein. It should be understood, however, that the server **1200** might include a variety of alternative devices for performing one or more like functions, without departing from the spirit and scope of the present invention. For example, at least a portion of the server **1200**, in certain embodiments, may be located on the distributed device(s) **1110**, **1120**, and/or the handheld or mobile device(s) **1300**, as may be desirable for particular applications. As will be described in further detail below, in at least one embodiment, the handheld or mobile device(s) **1300** may contain one or more mobile applications **1330** which may be configured so as to provide a user interface for communication with the server **1200**, all as will be likewise described in further detail below.

[0083] FIG. 10A is a schematic diagram of the server **1200** according to various embodiments. The server **1200** includes a processor **1230** that communicates with other elements within the server via a system interface or bus **1235**. Also included in the server **1200** is a display/input device **1250** for receiving and displaying data. This display/input device **1250** may be, for example, a keyboard or pointing device that is used in combination with a monitor. The server **1200** further includes memory **1220**, which preferably includes both read only memory (ROM) **1226** and random access memory (RAM) **1222**. The server's ROM **1226** is used to store a basic input/output system **1224** (BIOS), containing the basic routines that help to transfer information between elements within the server **1200**. Various ROM and RAM configurations have been previously described herein.

[0084] In addition, the server **1200** includes at least one storage device or program storage **210**, such as a hard disk drive, a floppy disk drive, a CD Rom drive, or optical disk drive, for storing information on various computer-readable media, such as a hard disk, a removable magnetic disk, or a CD-ROM disk. As will be appreciated by one of ordinary skill in the art, each of these storage devices **1210** are connected to the system bus **1235** by an appropriate interface. The storage devices **1210** and their associated computer-readable media provide nonvolatile storage for a personal computer. As will be appreciated by one of ordinary skill in the art, the computer-readable media described above could be replaced by any other type of computer-readable media known in the art. Such media include, for example, magnetic cassettes, flash memory cards, digital video disks, and Bernoulli cartridges.

[0085] Although not shown, according to an embodiment, the storage device **1210** and/or memory of the server **1200** may further provide the functions of a data storage device, which may store historical and/or current delivery data and delivery conditions that may be accessed by the server **1200**. In this regard, the storage device **1210** may comprise one or more databases. The term "database" refers to a structured collection of records or data that is stored in a computer

system, such as via a relational database, hierarchical database, or network database and as such, should not be construed in a limiting fashion.

[0086] A number of program modules (e.g., exemplary modules **1400-1700**) comprising, for example, one or more computer-readable program code portions executable by the processor **1230**, may be stored by the various storage devices **1210** and within RAM **1222**. Such program modules may also include an operating system **1280**. In these and other embodiments, the various modules **1400**, **1500**, **1600**, **1700** control certain aspects of the operation of the server **1200** with the assistance of the processor **1230** and operating system **1280**. In still other embodiments, it should be understood that one or more additional and/or alternative modules may also be provided, without departing from the scope and nature of the present invention.

[0087] In various embodiments, the program modules **1400**, **1500**, **1600**, **1700** are executed by the server **1200** and are configured to generate one or more graphical user interfaces, reports, instructions, and/or notifications/alerts, all accessible and/or transmittable to various users of the system **1020**. In certain embodiments, the user interfaces, reports, instructions, and/or notifications/alerts may be accessible via one or more networks **1130**, which may include the Internet or other feasible communications network, as previously discussed.

[0088] In various embodiments, it should also be understood that one or more of the modules **1400**, **1500**, **1600**, **1700** may be alternatively and/or additionally (e.g., in duplicate) stored locally on one or more of the devices **1110**, **1120**, and/or **1300** and may be executed by one or more processors of the same. According to various embodiments, the modules **1400**, **1500**, **1600**, **1700** may send data to, receive data from, and utilize data contained in one or more databases, which may be comprised of one or more separate, linked and/or networked databases.

[0089] Also located within the server **1200** is a network interface **1260** for interfacing and communicating with other elements of the one or more networks **1130**. It will be appreciated by one of ordinary skill in the art that one or more of the server **1200** components may be located geographically remotely from other server components. Furthermore, one or more of the server **1200** components may be combined, and/or additional components performing functions described herein may also be included in the server.

[0090] While the foregoing describes a single processor **1230**, as one of ordinary skill in the art will recognize, the server **1200** may comprise multiple processors operating in conjunction with one another to perform the functionality described herein. In addition to the memory **1220**, the processor **1230** can also be connected to at least one interface or other means for displaying, transmitting and/or receiving data, content or the like. In this regard, the interface(s) can include at least one communication interface or other means for transmitting and/or receiving data, content or the like, as well as at least one user interface that can include a display and/or a user input interface, as will be described in further detail below. The user input interface, in turn, can comprise any of a number of devices allowing the entity to receive data from a user, such as a keypad, a touch display, a joystick or other input device.

[0091] Still further, while reference is made to the "server" **1200**, as one of ordinary skill in the art will recognize, embodiments of the present invention are not limited to tra-

ditionally defined server architectures. Still further, the system of embodiments of the present invention is not limited to a single server, or similar network entity or mainframe computer system. Other similar architectures including one or more network entities operating in conjunction with one another to provide the functionality described herein may likewise be used without departing from the spirit and scope of embodiments of the present invention. For example, a mesh network of two or more personal computers (PCs), similar electronic devices, or handheld portable devices, collaborating with one another to provide the functionality described herein in association with the server **1200** may likewise be used without departing from the spirit and scope of embodiments of the present invention.

[0092] According to various embodiments, many individual steps of a process may or may not be carried out utilizing the computer systems and/or servers described herein, and the degree of computer implementation may vary, as may be desirable and/or beneficial for one or more particular applications.

[0093] FIG. 10B provides an illustrative schematic representative of a mobile device **1300** that can be used in conjunction with various embodiments of the present invention. Mobile devices **1300** can be operated by various parties. As shown in FIG. 10B, a mobile device **1300** may include an antenna **1312**, a transmitter **1304** (e.g., radio), a receiver **1306** (e.g., radio), and a processing element **1308** that provides signals to and receives signals from the transmitter **1304** and receiver **1306**, respectively.

[0094] The signals provided to and received from the transmitter **1304** and the receiver **1306**, respectively, may include signaling data in accordance with an air interface standard of applicable wireless systems to communicate with various entities, such as the server **1200**, the distributed devices **1110**, **1120**, and/or the like. In this regard, the mobile device **1300** may be capable of operating with one or more air interface standards, communication protocols, modulation types, and access types. More particularly, the mobile device **1300** may operate in accordance with any of a number of wireless communication standards and protocols. In a particular embodiment, the mobile device **1300** may operate in accordance with multiple wireless communication standards and protocols, such as GPRS, UMTS, CDMA2000, 1xRTT, WCDMA, TD-SCDMA, LTE, E-UTRAN, EVDO, HSPA, HSDPA, Wi-Fi, WiMAX, UWB, IR protocols, Bluetooth protocols, USB protocols, and/or any other wireless protocol.

[0095] Via these communication standards and protocols, the mobile device **1300** may according to various embodiments communicate with various other entities using concepts such as Unstructured Supplementary Service data (USSD), Short Message Service (SMS), Multimedia Messaging Service (MMS), Dual-Tone Multi-Frequency Signaling (DTMF), and/or Subscriber Identity Module Dialer (SIM dialer). The mobile device **1300** can also download changes, add-ons, and updates, for instance, to its firmware, software (e.g., including executable instructions, applications, program modules), and operating system.

[0096] According to one embodiment, the mobile device **1300** may include a location determining device and/or functionality. For example, the mobile device **1300** may include a GPS module adapted to acquire, for example, latitude, longitude, altitude, geocode, course, and/or speed data. In one embodiment, the GPS module acquires data, sometimes

known as ephemeris data, by identifying the number of satellites in view and the relative positions of those satellites.

[0097] The mobile device **1300** may also comprise a user interface (that can include a display **1316** coupled to a processing element **1308**) and/or a user input interface (coupled to a processing element **308**). The user input interface can comprise any of a number of devices allowing the mobile device **1300** to receive data, such as a keypad **1318** (hard or soft), a touch display, voice or motion interfaces, or other input device. In embodiments including a keypad **1318**, the keypad can include (or cause display of) the conventional numeric (0-9) and related keys (#, \*), and other keys used for operating the mobile device **1300** and may include a full set of alphabetic keys or set of keys that may be activated to provide a full set of alphanumeric keys. In addition to providing input, the user input interface can be used, for example, to activate or deactivate certain functions, such as screen savers and/or sleep modes.

[0098] The mobile device **1300** can also include volatile storage or memory **1322** and/or non-volatile storage or memory **1324**, which can be embedded and/or may be removable. For example, the non-volatile memory may be ROM, PROM, EPROM, EEPROM, flash memory, MMCs, SD memory cards, Memory Sticks, CBRAM, PRAM, FeRAM, RRAM, SONOS, racetrack memory, and/or the like. The volatile memory may be RAM, DRAM, SRAM, FPM DRAM, EDO DRAM, SDRAM, DDR SDRAM, DDR2 SDRAM, DDR3 SDRAM, RDRAM, RIMM, DIMM, SIMM, VRAM, cache memory, register memory, and/or the like. The volatile and non-volatile storage or memory can store databases, database instances, database mapping systems, data, applications, programs, program modules, scripts, source code, object code, byte code, compiled code, interpreted code, machine code, executable instructions, and/or the like to implement the functions of the mobile device **1300**.

[0099] The mobile device **1300** may also include one or more of a camera **1326** and a mobile application **1330**. The camera **1326** may be configured according to various embodiments as an additional and/or alternative data collection feature, whereby one or more items may be read, stored, and/or transmitted by the mobile device **1300** via the camera. The mobile application **1330** may further provide a feature via which various tasks may be performed with the mobile device **1300**. Various configurations may be provided, as may be desirable for one or more users of the mobile device **1300** and the system **1020** as a whole.

[0100] The invention is not limited to the above-described embodiments and many modifications are possible within the scope of the following claims. Such modifications may, for example, involve using a different source of energy beam than the exemplified electron beam such as a laser beam. Other materials than metallic powder may be used, such as the non-limiting examples of: electrically conductive polymers and powder of electrically conductive ceramics. Indeed, a person of ordinary skill in the art would be able to use the information contained in the preceding text to modify various embodiments of the invention in ways that are not literally described, but are nevertheless encompassed by the attached claims, for they accomplish substantially the same functions to reach substantially the same results. Therefore, it is to be understood that the invention is not limited to the specific embodiments disclosed and that modifications and other embodiments are intended to be included within the scope of the appended claims. Although specific terms are employed

herein, they are used in a generic and descriptive sense only and not for purposes of limitation.

That which is claimed:

**1.** A method for welding a workpiece, said method comprising the steps of:

making a first weld at a first position on said workpiece with a high energy beam;

deflecting the high energy beam with at least one deflection lens to make a second weld at a second position on said workpiece;

focusing the high energy beam on said workpiece with at least one focusing lens; and

shaping the high energy beam on said workpiece with at least one astigmatism lens so that the shape of the high energy beam on said workpiece is longer in a direction parallel to a deflection direction of said high energy beam than in a direction perpendicular to said deflection direction of said high energy beam,

wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is varying as a function of the power of said energy beam on said workpiece.

**2.** The method according to claim **1**, wherein said high energy beam is at least one of an electron beam or a laser beam.

**3.** The method according to claim **1**, wherein said deflection source is at least one of a tiltable mirror or a tiltable lens.

**4.** The method according to claim **1**, wherein said deflection source is a deflection coil.

**5.** The method according to claim **1**, wherein said workpiece is a powder material layer in an additive manufacturing process.

**6.** The method according to claim **1**, wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is also varying as a function of the position of said high energy beam on said workpiece.

**7.** The method according to claim **1**, wherein said energy beam is at least five (5) times longer in a direction parallel to the deflection direction compared to a direction perpendicular to said deflection direction.

**8.** The method according to claim **1**, wherein said energy beam is at least ten (10) times longer in a direction parallel to the deflection direction compared to a direction perpendicular to said deflection direction.

**9.** The method according to claim **1**, wherein a mean spot size on said workpiece in a direction perpendicular to the scanning direction is smaller than a mean spot size on said workpiece in a direction parallel to the scanning direction for a full scan length, a full cross section and/or for a full 3-dimensional article.

**10.** The method according to claim **1**, wherein one or more of the steps of deflecting, focusing, and shaping the high energy beam are performed via execution of one or more computer processors.

**11.** A method of using of an astigmatism lens in additive manufacturing for forming a three-dimensional article through successive fusion, with a high energy beam, of parts of at least one layer of a powder bed provided on a work table, which parts correspond to successive cross sections of the three dimensional article, said method comprising the step of:

using said astigmatism lens to prolong the size the high energy beam on said layer of powder bed in a direction parallel to a deflection direction more than in a direction perpendicular to said deflection direction,

wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is varying as a function of the power of said energy beam on said workpiece.

**12.** A method for forming a three-dimensional article through successively depositing individual layers of powder material that are fused together so as to form the article, said method comprising the steps of:

providing at least one high energy beam source for emitting a high energy beam for at least one of heating or fusing said powder material;

providing a deflection source for deflecting the high energy beam on said powder material;

providing a focus lens for focusing said high energy beam on said powder material; and

shaping the high energy beam on said powder layer with at least one astigmatism lens so that the shape of the high energy beam on said layer of powder is longer in a direction parallel to a deflection direction of said high energy beam than in a direction perpendicular to said deflection direction of said high energy beam,

wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is varying as a function of the power of said energy beam on said workpiece.

**13.** The method according to claim **12**, wherein said high energy beam is at least one of an electron beam or a laser beam.

**14.** The method according to claim **12**, wherein said deflection source is at least one of a tiltable mirror or a tiltable lens.

**15.** The method according to claim **12**, wherein said deflection source is a deflection coil.

**16.** The method according to claim **12**, wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is also varying as a function of the position of said high energy beam on said workpiece.

**17.** The method according to claim **12**, wherein said energy beam is at least five (5) times longer in a direction parallel to the deflection direction compared to a direction perpendicular to said deflection direction.

**18.** The method according to claim **12**, wherein said energy beam is at least ten (10) times longer in a direction parallel to the deflection direction compared to a direction perpendicular to said deflection direction.

**19.** The method according to claim **12**, wherein a mean spot size on said workpiece in a direction perpendicular to the scanning direction is smaller than a mean spot size on said workpiece in a direction parallel to the scanning direction for a full scan length, a full cross section and/or for a full 3-dimensional article.

**20.** The method according to claim **12**, wherein:

the method further comprises the step of receiving and storing, within one or more memory storage areas, a model of said at least one three-dimensional article; and at least the step of shaping the high energy beam is performed via execution of one or more computer processors.

**21.** An apparatus for forming a three-dimensional article through successively depositing individual layers of powder material that are fused together so as to form the article, said apparatus comprising:

at least one high energy beam source for emitting a high energy beam for at least one of heating or fusing said powder material;

a deflection source for deflecting the high energy beam on said powder material;  
 a focus lens for focusing said high energy beam on said powder material;  
 at least one astigmatism lens; and  
 at least one controller configured to control said at least one astigmatism lens so as to shape the high energy beam on said powder layer such that the shape of the high energy beam on said layer of powder is longer in a direction parallel to a deflection direction of said high energy beam than in a direction perpendicular to said deflection direction of said high energy beam, wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is varying as a function of the power of said energy beam on said workpiece.

**22.** The apparatus according to claim **21**, wherein said high energy beam is at least one of an electron beam or a laser beam.

**23.** The apparatus according to claim **21**, wherein said deflection source is at least one of a tiltable mirror or a tiltable lens or a deflection coil.

**24.** The apparatus according to claim **21**, wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is also varying as a function of the position of said high energy beam on said workpiece.

**25.** The apparatus according to claim **21**, wherein said energy beam is at least five (5) times longer in a direction parallel to the deflection direction compared to a direction perpendicular to said deflection direction.

**26.** The apparatus according to claim **21**, wherein said energy beam is at least ten (10) times longer in a direction parallel to the deflection direction compared to a direction perpendicular to said deflection direction.

**27.** The apparatus according to claim **21**, wherein a mean spot size on said workpiece in a direction perpendicular to the scanning direction is smaller than a mean spot size on said workpiece in a direction parallel to the scanning direction for a full scan length, a full cross section and/or for a full 3-dimensional article.

**28.** An apparatus for welding a workpiece, said apparatus comprising:

a high energy beam configured to make a first weld at a first position on said workpiece;  
 at least one deflection lens configured to deflect the high energy beam so as to cause the high energy beam to make a second weld at a second position on said workpiece;  
 at least one focusing lens configured to focus the high energy beam on said workpiece; and  
 at least one astigmatism lens; and  
 at least one controller configured to:

shape the high energy beam on said workpiece with said at least one astigmatism lens so that the shape of the high energy beam on said workpiece is longer in a direction parallel to a deflection direction of said high energy beam than in a direction perpendicular to said deflection direction of said high energy beam,

wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is varying as a function of the power of said energy beam on said workpiece.

**29.** A computer program product for forming a three-dimensional article through successively depositing individual layers of powder material that are fused together so as to form the article, the computer program product comprising at least one non-transitory computer-readable storage medium having computer-readable program code portions stored therein, the computer-readable program code portions comprising:

an executable portion configured to provide at least one high energy beam source for emitting a high energy beam for at least one of heating or fusing said powder material;

an executable portion configured to provide a deflection source for deflecting the high energy beam on said powder material;

an executable portion configured to provide a focus lens for focusing said high energy beam on said powder material;

an executable portion configured to shape the high energy beam on said powder layer with at least one astigmatism lens so that the shape of the high energy beam on said layer of powder is longer in a direction parallel to a deflection direction of said high energy beam than in a direction perpendicular to said deflection direction of said high energy beam,

wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is varying as a function of the power of said energy beam on said workpiece.

**30.** A computer program product for welding a workpiece, the computer program product comprising at least one non-transitory computer-readable storage medium having computer-readable program code portions stored therein, the computer-readable program code portions comprising:

an executable portion configured to make a first weld at a first position on said workpiece with a high energy beam;

an executable portion configured to deflect the high energy beam with at least one deflection lens for making a second weld at a second position on said workpiece;

an executable portion configured to focus the high energy beam on said workpiece with at least one focusing lens; and

an executable portion configured to shape the high energy beam on said workpiece with at least one astigmatism lens so that the shape of the high energy beam on said workpiece is longer in a direction parallel to a deflection direction of said high energy beam than in a direction perpendicular to said deflection direction of said high energy beam,

wherein a ratio of a length of said high energy beam in said parallel direction and said perpendicular direction is varying as a function of the power of said energy beam on said workpiece.
