ABSTRACT

A depth camera assembly (DCA) determines distances between the DCA and objects in a local area within a field of view of the DCA. The DCA projects a series of sinusoidal patterns into the local area DCA and captures images of the sinusoidal patterns via a sensor. Each pixel of the augmented sensor includes a plurality of charge bins, and charge accumulated by a photodiode of a pixel during different time intervals (e.g., times when different sinusoidal patterns are emitted) is stored in a different charge storage bin. Charge may be retrieved from different charge storage bins to determine depth from the DCA.

APPLICATIONS**

[0001] This application is a continuation of U.S. patent application Ser. No. 16/298,278, which claims the benefit of U.S. Provisional Application No. 62/642,199, filed Mar. 13, 2018, which are incorporated by reference in its entirety.

BACKGROUND

[0002] The present disclosure generally relates to virtual or augmented reality systems and more specifically relates to headsets for virtual reality systems that obtain depth information of a local area.

[0003] Providing virtual reality (VR) or augmented reality (AR) content to users through a head mounted display (HMD) often relies on localizing a user's position in an arbitrary environment and determining a three dimensional mapping of the surroundings within the arbitrary environment. The user's surroundings within the arbitrary environment may then be represented in a virtual environment or the user's surroundings may be overlaid with additional content.

[0004] Conventional HMDs include one or more quantitative depth cameras to determine surroundings of a user within the user's environment. Typically, conventional depth cameras use structured light or time of flight to determine the HMD's location within an environment. Structured light depth cameras use an active illumination source to project known patterns into the environment surrounding the HMD. However, structured light commonly requires a pattern that is projected to be configured so different portions of the pattern include different characteristics that are later identified. Having different characteristics of different portions of the pattern causes significant portions of a resulting image of the projected pattern to not be illuminated. This inefficiently uses a sensor capturing the resulting image; for example, projection of the pattern by a structured light depth camera results in less than 10% of sensor pixels collecting light from the projected pattern, while requiring multiple sensor pixels to be illuminated to perform a single depth measurement.

[0005] Time of flight depth cameras measure a round trip travel time of light projected into the environment surrounding a depth camera and returning to pixels on a sensor array. While time of flight depth cameras are capable of measure depths of different objects in the environment independently via each sensor pixel, light incident on a sensor pixel may be a combination of light received from multiple optical paths in the environment surrounding the depth camera. Existing techniques to resolve the optical paths of light incident on a sensor pixels are computationally complex and do not fully disambiguate between optical paths in the environment.

SUMMARY

[0006] A headset in a virtual reality (VR) or augmented reality (AR) system environment includes a depth camera assembly (DCA) configured to determine distances between a head mounted display (HMD) and one or more objects in an area surrounding the HMD and within a field of view of an imaging device included in the headset (i.e., a "local

area"). The DCA includes the imaging device, such as a camera, and an illumination source that is displaced by a specific distance relative to the illumination source. The illumination source is configured to emit a series of periodic illumination patterns (e.g., a sinusoid) into the local area. Each periodic illumination pattern of the series is phase shifted by a different amount. The periodicity of the illumination pattern is a spatial periodicity observed on an object illuminated by the illumination pattern, and the phase shifts are lateral spatial phase shifts along the direction of periodicity. In various embodiments, the periodicity of the illumination pattern is in a direction that is parallel to a displacement between the illumination source and a center of the imaging device of the DCA.

[0007] The imaging device captures frames including the periodic illumination patterns via a sensor including multiple pixels and coupled to a processor. For each pixel of the sensor, the processor relates intensities captured by a pixel in multiple images to a phase shift of a periodic illumination pattern captured by the multiple images. From the phase shift of the periodic illumination pattern captured by the pixel, the processor determines a depth of a location within the local area from which the pixel captured the intensities of the periodic illumination pattern from the HMD. Each pixel of the sensor may independently determine a depth based on captured intensities of the periodic illumination pattern, optimally using the pixels of the sensor of the DCA.

[0008] In various embodiments, each pixel of the sensor comprises a photodiode coupled to multiple charge storage bins by transfer gates. For example, a pixel of the sensor includes a photodiode coupled to three charge storage bins, with a different transfer gate coupling the photodiode to different charge storage bins. At different times, the pixel receives a control signal opening a specific transfer gate, while other transfer gates remain closed. Charge accumulated by the photodiode of the pixel is accumulated in the charge storage bin via the opened specific transfer gate. Subsequently, the specific transfer gate is closed and charge is accumulated by the photodiode. A subsequent control signal received by the pixel opens another transfer gate at a different time, so charge accumulated by the photodiode is accumulated in another charge storage bin through the other transfer gate. In various embodiments, different transfer gates are opened at different times when the illumination source emits the periodic illumination pattern. For example, a first transfer gate is opened, while other transfer gates remain closed, during a time interval when the illumination source emits the periodic illumination pattern. The first transfer gate is closed when the illumination source stops emitting the periodic illumination pattern. Subsequently, a different transfer gate is opened when the illumination source emits the periodic illumination pattern during another time interval, while the first transfer gate and other transfer gates are closed. Hence, different charge storage bins store charge accumulated by the sensor at different times. Charge accumulated in different charge storage bins is retrieved and used to determine depth of a location in the local area from which the pixel captured intensity of light.

[0009] In some embodiments a method is described. It is determined that an illumination source is emitting a first periodic illumination pattern during a first time interval. During the first time interval, a first control sensor is communicated to a sensor, the first control signal opening a first transfer gate coupling a photodiode of a pixel to a first

charge storage bin and other control signals closing other transfer gates coupling the photodiode of the pixel to other charge storage bins apart from the first charge storage bin. It is determined that the illumination source is emitting a second periodic illumination pattern having a different spatial phase shift during a second time interval. During the second time interval, a second control signal is communicated to the sensor, the second control signal opening up a second transfer gate coupling the photodiode of the pixel to a second charge storage bin and other control signals closing other transfer gates coupling the photodiode of the pixel to other charge storage bins apart from the second charge storage bin.

BRIEF DESCRIPTION OF THE DRAWINGS

[0010] FIG. 1 is a block diagram of a system environment for providing virtual reality or augmented reality content, in accordance with an embodiment.

[0011] FIG. 2 is a diagram of a head mounted display (HMD), in accordance with an embodiment.

[0012] FIG. 3 is a cross section of a front rigid body of a head mounted display (HMD), in accordance with an embodiment.

[0013] FIG. 4 is an example of light emitted into a local area and captured by a depth camera assembly, in accordance with an embodiment.

[0014] FIG. 5 is an example of using multiple frequencies of a continuous intensity pattern of light emitted by a DCA to identify a phase shift for a pixel of the sensor, in accordance with an embodiment.

[0015] FIG. 6A is an example pixel of a sensor included in an imaging device of a depth camera assembly, in accordance with an embodiment.

[0016] FIG. 6B is an example of control signals operating the example pixel shown in FIG. 6A, in accordance with an embodiment.

[0017] FIG. 7 is another example of control signals operating the example pixel shown in FIG. 6A, in accordance with an embodiment.

[0018] The figures depict embodiments of the present disclosure for purposes of illustration only. One skilled in the art will readily recognize from the following description that alternative embodiments of the structures and methods illustrated herein may be employed without departing from the principles, or benefits touted, of the disclosure described herein.

DETAILED DESCRIPTION

System Overview

[0019] FIG. 1 is a block diagram of one embodiment of a system environment 100 in which a console 110 operates. The system environment 100 shown in FIG. 1 may provide augmented reality (AR) or virtual reality (VR) content to users in various embodiments. Additionally or alternatively, the system environment 100 generates one or more virtual environments and presents a virtual environment with which a user may interact to the user. The system environment 100 shown by FIG. 1 comprises a head mounted display (HMD) 105 and an input/output (I/O) interface 115 that is coupled to a console 110. While FIG. 1 shows an example system environment 100 including one HMD 105 and one I/O interface 115, in other embodiments any number of these

components may be included in the system environment 100. For example, there may be multiple HMDs 105 each having an associated I/O interface 115, with each HMD 105 and I/O interface 115 communicating with the console 110. In alternative configurations, different and/or additional components may be included in the system environment 100. Additionally, functionality described in conjunction with one or more of the components shown in FIG. 1 may be distributed among the components in a different manner than described in conjunction with FIG. 1 in some embodiments. For example, some or all of the functionality of the console 110 is provided by the HMD 105.

[0020] The head mounted display (HMD) 105 presents content to a user comprising augmented views of a physical, real-world environment with computer-generated elements (e.g., two dimensional (2D) or three dimensional (3D) images, 2D or 3D video, sound, etc.) or presents content comprising a virtual environment. In some embodiments, the presented content includes audio that is presented via an external device (e.g., speakers and/or headphones) that receives audio information from the HMD 105, the console 110, or both, and presents audio data based on the audio information. An embodiment of the HMD 105 is further described below in conjunction with FIGS. 2 and 3. The HMD 105 may comprise one or more rigid bodies, which may be rigidly or non-rigidly coupled to each other together. A rigid coupling between rigid bodies causes the coupled rigid bodies to act as a single rigid entity. In contrast, a non-rigid coupling between rigid bodies allows the rigid bodies to move relative to each other.

[0021] The HMD 105 includes a depth camera assembly (DCA) 120, an electronic display 125, an optics block 130, one or more position sensors 135, and an inertial measurement unit (IMU) 140. Some embodiments of The HMD 105 have different components than those described in conjunction with FIG. 1. Additionally, the functionality provided by various components described in conjunction with FIG. 1 may be differently distributed among the components of the HMD 105 in other embodiments.

[0022] The DCA 120 captures data describing depth information of an area surrounding the HMD 105. Some embodiments of the DCA 120 include one or more imaging devices (e.g., a camera, a video camera) and an illumination source configured to emit a series of periodic illumination patterns, with each periodic illumination pattern phase shifted by a different amount. As another example, the illumination source emits a series of sinusoids that each have a specific spatial phase shift. The periodicity of the illumination pattern is a spatial periodicity observed on an object illuminated by the illumination pattern, and the phase shifts are lateral spatial phase shifts along the direction of periodicity. In various embodiments, the periodicity of the illumination pattern is in a direction that is parallel to a displacement between the illumination source and a center of the imaging device of the DCA 120

[0023] For example, the illumination source emits a series of sinusoids that each have a different spatial phase shift into an environment surrounding the HMD 105. In other examples, the illumination source emits a sinusoidal pattern multiplied by a low frequency envelope, such as a Gaussian, which changes relative signal intensity over the field of view of the imaging device. This change in relative signal intensity over the imaging device's field of view changes temporal noise characteristics without affecting the depth deter-

mination, which is further described below in conjunction with FIGS. 4 and 5 provided the higher frequency signal is a sinusoid. The imaging device of the DCA 120 includes a sensor comprising multiple pixels that determine a phase shift of a periodic illumination pattern included in multiple images captured by the imaging device based on relative intensities included in the multiple captured images. As the phase shift is a function of depth, the DCA 120 determines a depth of a location within the local area from which images of the periodic illumination from the determined phase shift, as further described below in conjunction with FIGS. 4 and 5. In various embodiments, each pixel of the sensor of the imaging device determines a depth of a location within the local area from which a pixel captured intensities of the periodic illumination pattern based on a phase shift determined for the periodic illumination pattern captured by the pixel.

[0024] The imaging device captures and records particular ranges of wavelengths of light (i.e., “bands” of light). Example bands of light captured by an imaging device include: a visible band (~380 nm to 750 nm), an infrared (IR) band (~750 nm to 2,200 nm), an ultraviolet band (100 nm to 380 nm), another portion of the electromagnetic spectrum, or some combination thereof. In some embodiments, an imaging device captures images including light in the visible band and in the infrared band.

[0025] The electronic display 125 displays 2D or 3D images to the user in accordance with data received from the console 110. In various embodiments, the electronic display 125 comprises a single electronic display or multiple electronic displays (e.g., a display for each eye of a user). Examples of the electronic display 125 include: a liquid crystal display (LCD), an organic light emitting diode (OLED) display, an active-matrix organic light-emitting diode display (AMOLED), some other display, or some combination thereof.

[0026] The optics block 130 magnifies image light received from the electronic display 125, corrects optical errors associated with the image light, and presents the corrected image light to a user of the HMD 105. In various embodiments, the optics block 130 includes one or more optical elements. Example optical elements included in the optics block 130 include: an aperture, a Fresnel lens, a convex lens, a concave lens, a filter, a reflecting surface, or any other suitable optical element that affects image light. Moreover, the optics block 130 may include combinations of different optical elements. In some embodiments, one or more of the optical elements in the optics block 130 may have one or more coatings, such as anti-reflective coatings.

[0027] Magnification and focusing of the image light by the optics block 130 allows the electronic display 125 to be physically smaller, weigh less and consume less power than larger displays. Additionally, magnification may increase the field of view of the content presented by the electronic display 125. For example, the field of view of the displayed content is such that the displayed content is presented using almost all (e.g., approximately 110 degrees diagonal), and in some cases all, of the user’s field of view. Additionally, in some embodiments, the amount of magnification may be adjusted by adding or removing optical elements.

[0028] In some embodiments, the optics block 130 may be designed to correct one or more types of optical error. Examples of optical error include barrel distortions, pin-cushion distortions, longitudinal chromatic aberrations, or

transverse chromatic aberrations. Other types of optical errors may further include spherical aberrations, comatic aberrations or errors due to the lens field curvature, astigmatism, or any other type of optical error. In some embodiments, content provided to the electronic display 125 for display is pre-distorted, and the optics block 130 corrects the distortion when it receives image light from the electronic display 125 generated based on the content.

[0029] The IMU 140 is an electronic device that generates data indicating a position of the HMD 105 based on measurement signals received from one or more of the position sensors 135 and from depth information received from the DCA 120. A position sensor 135 generates one or more measurement signals in response to motion of the HMD 105. Examples of position sensors 135 include: one or more accelerometers, one or more gyroscopes, one or more magnetometers, another suitable type of sensor that detects motion, a type of sensor used for error correction of the IMU 140, or some combination thereof. The position sensors 135 may be located external to the IMU 140, internal to the IMU 140, or some combination thereof.

[0030] Based on the one or more measurement signals from one or more position sensors 135, the IMU 140 generates data indicating an estimated current position of the HMD 105 relative to an initial position of the HMD 105. For example, the position sensors 135 include multiple accelerometers to measure translational motion (forward/back, up/down, left/right) and multiple gyroscopes to measure rotational motion (e.g., pitch, yaw, roll). In some embodiments, the IMU 140 rapidly samples the measurement signals and calculates the estimated current position of the HMD 105 from the sampled data. For example, the IMU 140 integrates the measurement signals received from the accelerometers over time to estimate a velocity vector and integrates the velocity vector over time to determine an estimated current position of a reference point on the HMD 105. Alternatively, the IMU 140 provides the sampled measurement signals to the console 110, which interprets the data to reduce error. The reference point is a point that may be used to describe the position of the HMD 105. The reference point may generally be defined as a point in space or a position related to the HMD’s 105 orientation and position.

[0031] The IMU 140 receives one or more parameters from the console 110. As further discussed below, the one or more parameters are used to maintain tracking of the HMD 105. Based on a received parameter, the IMU 140 may adjust one or more IMU parameters (e.g., sample rate). In some embodiments, certain parameters cause the IMU 140 to update an initial position of the reference point so it corresponds to a next position of the reference point. Updating the initial position of the reference point as the next calibrated position of the reference point helps reduce accumulated error associated with the current position estimated the IMU 140. The accumulated error, also referred to as drift error, causes the estimated position of the reference point to “drift” away from the actual position of the reference point over time. In some embodiments of the HMD 105, the IMU 140 may be a dedicated hardware component. In other embodiments, the IMU 140 may be a software component implemented in one or more processors.

[0032] The I/O interface 115 is a device that allows a user to send action requests and receive responses from the console 110. An action request is a request to perform a

particular action. For example, an action request may be an instruction to start or end capture of image or video data or an instruction to perform a particular action within an application. The I/O interface 115 may include one or more input devices. Example input devices include: a keyboard, a mouse, a game controller, or any other suitable device for receiving action requests and communicating the action requests to the console 110. An action request received by the I/O interface 115 is communicated to the console 110, which performs an action corresponding to the action request. In some embodiments, the I/O interface 115 includes an IMU 140, as further described above, that captures calibration data indicating an estimated position of the I/O interface 115 relative to an initial position of the I/O interface 115. In some embodiments, the I/O interface 115 may provide haptic feedback to the user in accordance with instructions received from the console 110. For example, haptic feedback is provided when an action request is received, or the console 110 communicates instructions to the I/O interface 115 causing the I/O interface 115 to generate haptic feedback when the console 110 performs an action.

[0033] The console 110 provides content to the HMD 105 for processing in accordance with information received from one or more of: the DCA 120, the HMD 105, and the VR I/O interface 115. In the example shown in FIG. 1, the console 110 includes an application store 150, a tracking module 155 and a content engine 145. Some embodiments of the console 110 have different modules or components than those described in conjunction with FIG. 1. Similarly, the functions further described below may be distributed among components of the console 110 in a different manner than described in conjunction with FIG. 1.

[0034] The application store 150 stores one or more applications for execution by the console 110. An application is a group of instructions, that when executed by a processor, generates content for presentation to the user. Content generated by an application may be in response to inputs received from the user via movement of the HMD 105 or the I/O interface 115. Examples of applications include: gaming applications, conferencing applications, video playback applications, or other suitable applications.

[0035] The tracking module 155 calibrates the system environment 100 using one or more calibration parameters and may adjust one or more calibration parameters to reduce error in determination of the position of the HMD 105 or of the I/O interface 115. For example, the tracking module 155 communicates a calibration parameter to the DCA 120 to adjust the focus of the DCA 120 to more accurately determine depths of locations within the local area surrounding the HMD 105 from captured intensities. Calibration performed by the tracking module 155 also accounts for information received from the IMU 140 in the HMD 105 and/or an IMU 140 included in the I/O interface 115. Additionally, if tracking of the HMD 105 is lost (e.g., the DCA 120 loses line of sight of at least a threshold number of SL elements), the tracking module 140 may re-calibrate some or all of the system environment 100.

[0036] The tracking module 155 tracks movements of the HMD 105 or of the I/O interface 115 using information from the DCA 120, the one or more position sensors 135, the IMU 140 or some combination thereof. For example, the tracking module 155 determines a position of a reference point of the HMD 105 in a mapping of a local area based on information

from the HMD 105. The tracking module 155 may also determine positions of the reference point of the HMD 105 or a reference point of the I/O interface 115 using data indicating a position of the HMD 105 from the IMU 140 or using data indicating a position of the I/O interface 115 from an IMU 140 included in the I/O interface 115, respectively. Additionally, in some embodiments, the tracking module 155 may use portions of data indicating a position of the HMD 105 from the IMU 140 as well as representations of the local area from the DCA 120 to predict a future location of the HMD 105. The tracking module 155 provides the estimated or predicted future position of the HMD 105 or the I/O interface 115 to the content engine 145.

[0037] The content engine 145 generates a 3D mapping of the area surrounding the HMD 105 (i.e., the “local area”) based on information received from the DCA 120 included in the HMD 105. In some embodiments, the content engine 145 determines depth information for the 3D mapping of the local area based on depths determined by each pixel of the sensor in the imaging device from a phase shift determined from relative intensities captured by a pixel of the sensor in multiple images. In various embodiments, the content engine 145 uses different types of information determined by the DCA 120 or a combination of types of information determined by the DCA 120 to generate the 3D mapping of the local area.

[0038] The content engine 145 also executes applications within the system environment 100 and receives position information, acceleration information, velocity information, predicted future positions, or some combination thereof, of the HMD 105 from the tracking module 155. Based on the received information, the content engine 145 determines content to provide to the HMD 105 for presentation to the user. For example, if the received information indicates that the user has looked to the left, the content engine 145 generates content for the HMD 105 that mirrors the user’s movement in a virtual environment or in an environment augmenting the local area with additional content. Additionally, the content engine 145 performs an action within an application executing on the console 110 in response to an action request received from the I/O interface 115 and provides feedback to the user that the action was performed. The provided feedback may be visual or audible feedback via the HMD 105 or haptic feedback via the I/O interface 115.

Head Mounted Display

[0039] FIG. 2 is a wire diagram of one embodiment of a head mounted display (HMD) 200. The HMD 200 is an embodiment of the HMD 105, and includes a front rigid body 205, a band 210, a reference point 215, a left side 220A, a top side 220B, a right side 220C, a bottom side 220D, and a front side 220E. The HMD 200 shown in FIG. 2 also includes an embodiment of a depth camera assembly (DCA) 120 including an imaging device 225 and an illumination source 230, which are further described below in conjunction with FIGS. 3 and 4. The front rigid body 205 includes one or more electronic display elements of the electronic display 125 (not shown), the IMU 130, the one or more position sensors 135, and the reference point 215.

[0040] In the embodiment shown by FIG. 2, the HMD 200 includes a DCA 120 comprising an illumination source 225, such as a camera, and an illumination source 230 configured to emit a series of periodic illumination patterns, with each

periodic illumination pattern phase shifted by a different amount into a local area surrounding the HMD 200. In various embodiments, the illumination source 230 emits a sinusoidal pattern, a near sinusoidal pattern, or any other periodic pattern (e.g., a square wave). For example, the illumination source 230 emits a series of sinusoids that each have a different phase shift into an environment surrounding the HMD 200. In various embodiments, the illumination source 230 includes an acousto-optic modulator configured to generate two Gaussian beams of light that interfere with each other in the local area so a sinusoidal interference pattern is generated. However, in other embodiments the illumination source 230 includes one or more of an acousto-optic device, an electro-optic device, physical optics, optical interference, a diffractive optical device, or any other suitable components configured to generate the periodic illumination pattern. In some embodiments, the illumination source 230 includes additional optical elements that modify the generated sinusoidal interference pattern to be within an intensity envelope (e.g., within a Gaussian intensity pattern); alternatively, the HMD 200 includes the additional optical elements and the Gaussian beams of light generated by the illumination source 230 are directed through the additional optical elements before being emitted into the environment surrounding the HMD 200. The imaging device 225 captures images of the local area, which are used to calculate depths relative to the HMD 200 of various locations within the local area, as further described below in conjunction with FIGS. 3-5.

[0041] FIG. 3 is a cross section of the front rigid body 205 of the HMD 200 depicted in FIG. 2. As shown in FIG. 3, the front rigid body 205 includes an imaging device 225 and an illumination source 230. The front rigid body 205 also has an optical axis corresponding to a path along which light propagates through the front rigid body 205. In some embodiments, the imaging device 225 is positioned along the optical axis and captures images of a local area 305, which is a portion of an environment surrounding the front rigid body 205 within a field of view of the imaging device 225. Additionally, the front rigid body 205 includes the electronic display 125 and the optics block 130, which are further described above in conjunction with FIG. 1. The front rigid body 205 also includes an exit pupil 335 where the user's eye 340 is located. For purposes of illustration, FIG. 3 shows a cross section of the front rigid body 205 in accordance with a single eye 340. The local area 305 reflects incident ambient light as well as light projected by the illumination source 230, which is subsequently captured by the imaging device 225.

[0042] As described above in conjunction with FIG. 1, the electronic display 125 emits light forming an image toward the optics block 130, which alters the light received from the electronic display 125. The optics block 130 directs the altered image light to the exit pupil 335, which is a location of the front rigid body 205 where a user's eye 340 is positioned. FIG. 3 shows a cross section of the front rigid body 205 for a single eye 340 of the user, with another electronic display 125 and optics block 130, separate from those shown in FIG. 3, included in the front rigid body 205 to present content, such as an augmented representation of the local area 305 or virtual content, to another eye of the user.

[0043] As further described above in conjunction with FIG. 2, the illumination source 230 of the depth camera

assembly (DCA) emits a series of periodic illumination patterns, with each periodic illumination pattern phase shifted by a different amount into the local area 305, and the imaging device 225 captures images of the periodic illumination patterns projected onto the local area 305 using a sensor comprising multiple pixels. Each pixel captures intensity of light emitted by the illumination source 230 from the local area 305 in various images and communicates the captured intensity to a controller or to the console 110, which determines a phase shift for each image, as further described below in conjunction with FIGS. 4-6B, and determines a depth of a location within the local area onto which the light emitted by the illumination source 230 captured by the imaging device 225 was captured, also further described below in conjunction with FIGS. 4-6B.

Depth Camera Assembly

[0044] FIG. 4 example of light emitted into a local area and captured by a depth camera assembly included in a head mounted display (HMD) 105. FIG. 4 shows an imaging device 225 and an illumination source 230 of a depth camera assembly (DCA) 120 included in the HMD. As shown in FIG. 4, imaging device 225 and the illumination source 230 are separated by a specific distance D (also referred to as a "baseline"), which is specified when the DCA 120 is assembled. The distance D between the imaging device 225 and the illumination source 230 is stored in a storage device coupled to the imaging device 225, coupled to a controller included in the DCA 120, or coupled to the console 110 in various embodiments.

[0045] In the example of FIG. 4, the illumination source 230 emits a smooth continuous intensity pattern of light 405 onto a flat target 410 within a local area surrounding the HMD 105 and within a field of view of the imaging device 225. The continuous intensity pattern of light 405 has a period T known to the DCA 120. However, in other embodiments, the illumination source 230 emits any suitable intensity pattern having a period T known to the DCA 120. Additionally, FIG. 4 identifies an angle θ_i that is one half of the period T of the continuous intensity pattern of light 405. As the continuous intensity pattern of light 405 scales laterally with the depth from the DCA 120, θ_i defines a depth independent periodicity of the illumination. Similarly, FIG. 4 depicts an angle θ_c and a line perpendicular to a plane including the imaging device 225 and a location on the target 410 from which a particular pixel of a sensor included in the imaging device 225 captures intensities of the continuous intensity pattern of light 405 in different images; hence, θ_c specifies an angle between the line perpendicular to the plane including the imaging device 225 and the location on the target 410 from which the specific pixel captures intensities of the continuous intensity pattern of light 405 emitted by the illumination source 230.

[0046] Each pixel of the sensor of the imaging device 225 provides an intensity of light from the continuous intensity pattern of light 405 captured in multiple images to a controller or to the console 110, which determines a phase shift, ϕ , of the continuous intensity pattern of light 405 captured by each pixel of the sensor. Each image captured by the imaging device 225 is a digital sampling of the continuous intensity pattern of light 405, so the set of images captured by the sensor represent a Fourier transform of the continuous intensity pattern of light 405, and the Fourier components, a_1 and b_1 , of the fundamental harmonic of the continuous

intensity pattern **405** are directly related to the phase shift for a pixel of the sensor. For images captured by a pixel of the sensor, the Fourier components a_1 and b_1 are determined using the following equations:

$$a_1 = \sum_{n=1}^N S_n \cos(\theta_n) \Delta\theta \quad (1)$$

$$b_1 = \sum_{n=1}^N S_n \sin(\theta_n) \Delta\theta \quad (2)$$

In the preceding, S_n denotes an intensity of the pixel of the sensor in a particular image, n , captured by the sensor, and the set θ_n of represents the phase shifts introduced into the continuous intensity pattern of light **405**. For example, if three phase shifts are used, the set of θ_n includes 0 degrees, 120 degrees, and 240 degrees. As another example, if four phase shifts are used the set of θ_n includes 0 degrees, 90 degrees, 180 degrees, and 270 degrees. In some embodiments, the set of θ_n is determines so 0 degrees and 360 degrees are uniformly sampled by the captured images, but the set of θ_n may include any values in different implementations.

[0047] From the Fourier components a_1 and b_1 determined as described above, the controller or the console determines the phase shift ϕ of the continuous intensity pattern of light **405** captured by a pixel of the sensor as follows:

$$\phi(R) = \tan^{-1}\left(\frac{a_1}{b_1}\right) - \theta_1 \quad (3)$$

$$R = \sqrt{a_1^2 + b_1^2} \quad (4)$$

[0048] In the preceding, ϕ is the phase shift of the first harmonic of the continuous intensity pattern of light **405**, R is the magnitude of the first harmonic of the continuous intensity pattern of light **405**, and θ_1 is a calibration offset. For each spatial frequency of the continuous intensity pattern of light **405**, the DCA **120** determines phase shifts using the intensity of the pixel of the sensor in at least three images.

[0049] The phase shift of the first harmonic of the continuous intensity pattern **405** determined through equation (3) above is used by a controller **430** coupled to the imaging device **225** and to the illumination source **230**. In various embodiments the controller **430** is a processor that may be included in in the imaging device **225**, in the illumination source **230**, or in the console **110** to determine the depth of the location of the target **410** from which the pixel of the sensor captures intensities of the continuous intensity pattern of light **405** as follows:

$$z = \frac{D}{\frac{\tan(\theta_i)}{\pi}(\phi_{ij} - \phi_{ij,cal}) - \tan(\theta_c)} \quad (5)$$

Where z is the depth of the location of the target **410** from which the pixel of the sensor captures intensities of the continuous intensity pattern of light **405**; D is the distance between the illumination source **230** and the imaging device

225; θ_i is one half of the period T of the continuous intensity pattern of light **405**; and θ_c is an angle between and a line perpendicular to a plane including the imaging device **225** and a the location on the target **410** from which a particular pixel located at row i and column j of the sensor included in the imaging device **225** captured intensities of the continuous intensity pattern of light **405**. Additionally, ϕ_{ij} is the phase shift determined for the pixel at row i and column j of the sensor, determined as further described above. Further, $\phi_{ij,cal}$ is a calibration offset for the pixel of the sensor at row i and column j of the sensor, which is determined as further described below.

[0050] The DCA **120** determines phase shifts for each of at least a set of pixels of the sensor of the imaging device **225**, as described above. For each of at least the set of pixels, the DCA **120** determines a depth from the DCA **120** to a location within the local area surrounding the DCA **120** from which a pixel of the set captured intensities of the continuous intensity pattern of light **405** emitted into the local area. This allows different pixels of the sensor of the imaging device **225** to determine depths of locations within the local area from which different pixels captured intensities of the continuous intensity pattern of light **405**. In some embodiments, each pixel of the sensor of the imaging device **225** determines a depth from the DCA **120** to a location within the local area surrounding the DCA **120** from which a pixel captured intensities of the continuous intensity pattern of light **405** in various images. The DCA **120** may generate a depth map identifying depths from the DCA **120** to different locations within the local area from which different pixels captured intensities of the continuous intensity pattern of light **405**. For example, the generated depth map identifies depths from the DCA **120** to different locations within the local area based on intensities captured by each pixel of the sensor, with a depth corresponding to a pixel of the sensor that captured intensities used to determine the depth.

[0051] However, because the phase shift is within a range of 0 and 2π radians, there may be ambiguities in resolving phase shifts that are integer multiples of 2π when determining the phase shift as described above. To avoid these potential ambiguities, in some embodiments, the continuous intensity pattern of light **405** emitted by the illumination source **230** as a single, relatively lower, spatial frequency; however, use of a relatively lower spatial frequency may decrease precision of the depth determination by the DCA **120**. Alternatively, the continuous intensity pattern of light **405** includes two or more spatial frequencies in sequence. Using two or more spatial frequencies increases a range of phases within which phase shifts may be unambiguously identified. The range of phases is extended for a subset of pixels within the sensor of the imaging device **225** based on a maximum parallax expected during operation of the imaging device **225**, which may be determined based on a difference between a maximum range and a minimum range of the imaging device **225**. Hence, the range of phases is extended for the subset of pixels of the sensor most likely to capture light from the continuous intensity pattern of light **405**.

[0052] FIG. 5 shows an example of using two frequencies of a continuous intensity pattern of light emitted by a DCA **120** to identify a phase shift for a pixel of the sensor. In the example of FIG. 5, phase shifts identified from frequency **505** repeat through the interval of 0 and 2π radians three times in a time interval, while phase shifts identified from

frequency **510** repeat through the interval of 0 and 2π radians twice in the time interval, as shown in plot **520**. Hence, emitting light patterns having frequency **505** and frequency **510** allows the DCA **120** to identify a phase shift in the time interval over a larger interval than between 0 and 2π (i.e., “unwraps” the phase shifts that may be unambiguously identified). FIG. **5** shows another example where, phase shifts identified from frequency **505** repeat through the interval of 0 and 2π radians five times in a time interval, while phase shifts identified from frequency **515** repeat through the interval of 0 and 2π radians twice in the time interval, as shown in plot **530**. This similarly allows the DCA **120** to identify a phase shift in the time interval over a larger interval than between 0 and 2π (i.e., “unwraps” the phase shifts that may be unambiguously identified). Additionally, FIG. **5** also shows an analogous three dimensional plot **540** of frequency **505**, frequency **510**, and frequency **515**, which may further extend the range of phases over which phase shifts may be unambiguously identified. In other embodiments, any number of frequencies of the continuous intensity pattern of light may be used to identify the phase shift for the pixel of the sensor using the process further described above.

Depth Camera Assembly Calibration

[**0053**] Referring again to FIG. **4**, a pixel of the sensor of the imaging device **225** captures intensity of the continuous intensity pattern of light **405** at a position of $D+x_0$ relative to the illumination source **230**, where x_0 is a distance from a principal point of the imaging device **225** (e.g., an optical center of a detector) along an axis separating the illumination source **230** and the sensor (e.g., along a horizontal axis along which the illumination source **230** and the sensor are positioned). As further described above in conjunction with FIG. **4**, the position of the pixel along the axis separating the illumination source **230** and the sensor is related to the phase shift, ϕ_{ij} , determined for the pixel. Additionally, as further described above θ_i defines the spatial periodicity of the continuous intensity pattern of light **405** in the local area and corresponds to half of the period T of the continuous intensity pattern of light. As the continuous intensity pattern of light **405** expands angularly as depth z from the DCA **120** increases, the period T of the continuous intensity pattern of light **405** corresponds to a specific depth z from the DCA **120**, while the periodicity defined by θ_i is independent of depth z from the DCA **120**. The dependence of the period T of the continuous intensity pattern of light **405**, in combination with the distance D between the imaging device **225** and the illumination source **230** allows the DCA **120** to determine the depth z of an object onto which the continuous intensity pattern of light **405** is emitted, as the lateral distance at which the pixel captures a phase, $D+x_0$, is equal to a product of the period T of the continuous intensity pattern of light **405** captured by the imaging device **225** and a ratio of the phase shift, ϕ_{ij} , determined for the pixel to 2π (i.e., $D+x_0=T(\phi_{ij}/2\pi)$). This relationship between the depth-dependent period T , the distance from a principal point of the imaging device **225**, and phase shift, ϕ_{ij} , determined for the pixel equates to an estimate of lateral extent at the camera plane and the plane including the object onto which the continuous intensity pattern of light **405** was emitted, which both measure a distance from a center of the continuous intensity pattern of light **405** to a central ray of the pixel.

[**0054**] The continuous intensity pattern of light **405** may be calibrated or determined using any suitable method, and scales with depth from the DCA **120**. Accordingly, the period T of the continuous intensity pattern of light **405** at the depth z from the DCA **120** is equal to double a product of the depth z from the DCA **120** and a tangent of the angle, θ_i , which defines half of the period T of the continuous intensity pattern of light (i.e., $T=2(z)(\tan(\theta_i))$). Similarly, the location of the pixel relative to the illumination source **230** along an axis separating the illumination source **230** and the sensor, x_0 , is a product of the depth from the DCA **120**, z , and a tangent of the angle, θ_c , between the line perpendicular to the plane including the imaging device **225** and the location on the target **410** from which the specific pixel captures intensities of the continuous intensity pattern of light **405** emitted by the illumination source **230** (i.e., $x_0=z(\tan(\theta_c))$). Accordingly,

$$D + z(\tan\theta_c) = 2z(\tan\theta_i)\left(\frac{\phi_{ij}}{2\pi}\right) \quad (6)$$

[**0055**] Solving equation 6 above for depth, z :

$$z = \frac{D}{\frac{\tan\theta_i}{\pi}\phi_{ij} - \tan\theta_c} \quad (7)$$

[**0056**] However, equation 7 above is based on the phase shift, ϕ_{ij} , when the location, x_0 , of the pixel relative to the illumination source **230** along equals the inverse of the specific distance D separating the imaging device **225** and the illumination source **230** is zero (i.e., $\phi_{ij}(x_0=D)=0$). To satisfy this condition, a calibration offset, $\phi_{ij,cal}$, is determined for each pixel via a calibration process where the sensor of the imaging device **225** captures intensities from the continuous illumination pattern of light **405** emitted onto a target at an accurately predetermined depth, z_{cal} . In various embodiments, the target is a Lambertian surface or other surface that reflects at least a threshold amount of light incident on the target. Accounting for the calibration offset modifies equation (7) above into equation (5),

$$z = \frac{D}{\frac{\tan(\theta_i)}{\pi}(\phi_{ij} - \phi_{ij,cal}) - \tan(\theta_c)},$$

which was previously described above in conjunction with FIG. **4**. With the predetermined depth, z_{cal} , the calibration offset for each pixel is determined as:

$$\phi_{ij,cal} = \phi_{ij} - \frac{\pi}{\tan\theta_i} \left[\frac{D}{z_{cal}} + \tan\theta_c \right] \quad (8)$$

[**0057**] The calibration offset is determined for each pixel of the sensor and for each frequency of the continuous intensity pattern of light **405** based on the predetermined depth z_{cal} and is stored in the DCA **120** for use during operation. A calibration offset for each pixel of the sensor is determined for each period of continuous intensity pattern of

light **405** emitted by the illumination source **230** and stored during the calibration process. For example, the DCA **120** stores a calibration offset for a pixel of the sensor in association with a location (e.g., a row and a column) of the pixel within the sensor and in association with a frequency of the continuous intensity pattern of light **405**. In various embodiments, the DCA **120** stores a parameterized function for determining the calibration offset of different pixels of the sensor based on location within the sensor and frequency of the continuous intensity pattern of light **405** instead of storing calibration offsets determined for individual pixels of the sensor. The DCA **120** stores a parameterized function corresponding to each period T of continuous intensity patterns of light **405** emitted by the illumination source **230** in various embodiments. In some embodiments, the parameterized function determining the calibration offset of different pixels is a linear function.

[0058] In embodiments where the illumination source **230** includes an acousto-optic modulator configured to generate two Gaussian beams of light that interfere with each other in the local area so a sinusoidal interference pattern is generated as the continuous intensity pattern of light **405** emitted into the local area, the period T of the continuous intensity pattern of light **405** is determined as:

$$\frac{T}{2} = \frac{z}{\sqrt{\left(\frac{2a}{\lambda}\right)^2 - 1}} \quad (9)$$

[0059] In equation **9**, λ is a wavelength of the illumination source **230** and a is the separation of the Gaussian beams generated by the acousto-optic modulator to generate the continuous intensity pattern of light **405** emitted into the local area surrounding the DCA **120**. The determined period T may then be used to determine the calibration offset for various pixels of the detector, as further described above.

Imaging Device Sensor

[0060] FIG. **6A** shows an example pixel **600** of a sensor included in an imaging device **225** of a depth camera assembly (DCA) **120**. In the example of FIG. **6**, the pixel **600** includes a photodiode **605** coupled to multiple charge storage bins **615**, **625**, **635**. While FIG. **6A** shows three charge storage bins **615**, **625**, **635** coupled to the photodiode **605**, in other embodiments, the pixel **600** is coupled to more than three charge storage bins **615**, **625**, **635**. The photodiode **605** is coupled to charge storage bin **615** via transfer gate **610**, coupled to charge storage bin **625** via transfer gate **620**, and coupled to charge storage bin **635** via transfer gate **630**.

[0061] A controller is coupled to the illumination source **230** of the DCA **120**, which is further described above in conjunction with FIG. **4**, and also to the sensor of the imaging device **225**. The controller provides control signals to transfer gate **610**, transfer gate **620**, and transfer **630** based on times when the illumination source **230** emits a periodic illumination pattern. In various embodiments, the illumination source **230** is activated to emit a periodic illumination pattern, is deactivated, and is activated again to emit another periodic illumination pattern. When the illumination source **230** is deactivated, the controller communicates control signals to transfer gate **610**, transfer gate **620**, and transfer

gate **630**. The control signals cause a single transfer gate **610**, **620**, **630** to open, while the other transfer gates **610**, **620**, **630** remain closed, so charge accumulated by the photodiode **605** while the illumination source **230** was activated is transferred to the charge storage bin **615**, **625**, **635** coupled to the photodiode via the open single transfer gate **610**, **620**, **630**. The open transfer gate **610**, **620**, **630** is closed when the illumination source **230** is again activated, and control signals from the controller open another transfer gate **610**, **620**, **630**, so charge accumulated by the photodiode **605** while the illumination source **230** was active is transferred to a charge storage bin **615**, **625**, **635** via the open transfer gate **610**, **620**, **630**.

[0062] FIG. **6B** is one example of control signals regulating operation of the pixel **600** shown in FIG. **6A**. For purposes of illustration, FIG. **6B** identifies a signal **650** indicating times when the illumination source **230** emits a periodic illumination pattern. When the signal **650** has a maximum value in FIG. **6B**, the illumination source **230** emits a periodic illumination pattern. FIG. **6B** also shows control signals provided to transfer gate **610**, transfer gate **620**, and transfer gate **630**. In the example of FIG. **6B**, when a control signal provided to a transfer gate **610**, **620**, **630** has a maximum value, the transfer gate **610**, **620**, **630** receiving the control signal is open; when the control signal provided to a transfer gate **610**, **620**, **630** has a minimum value, the transfer gate **610**, **620**, **630** is closed.

[0063] In the example of FIG. **6B**, when the illumination source **230** is initially activated and emits a periodic illumination pattern, transfer gate **610**, transfer gate **620**, and transfer gate **630** are closed. When the illumination source **230** is deactivated and stops emitting the periodic illumination pattern, transfer gate **610** receives a control signal that opens transfer gate **610**, while transfer gate **620** and transfer gate **630** remain closed. Charge accumulated by the photodiode **605** while the illumination source **230** was activated is transferred into charge storage bin **615** via transfer gate **610**. The control signal closes transfer gate **610** before the illumination source **230** is activated again, and the photodiode **605** accumulates charge from light captured while the illumination source **230** is activated. When the illumination source **230** is deactivated, transfer gate **620** receives a control signal that opens transfer gate **620**, while transfer gate **610** and transfer gate **630** remain closed; hence, charge accumulated by the photodiode **605** is transferred to charge storage bin **625**. The control signal closes transfer gate **620** before the illumination source **230** is activated, and the photodiode **605** accumulates charge from light captured while the illumination source **230** is activated. When the illumination source **230** is again deactivated, transfer gate **630** receives a control signal that opens transfer gate **630**, while transfer gate **610** and transfer gate **620** remain closed. Accordingly, charge accumulated by the photodiode **605** is transferred to charge storage bin **635**. Transfer gate **630** closes before the illumination source **230** is again activated, and the control signals received by transfer gate **610**, transfer gate **620**, and transfer gate **630** open and close the transfer gates **610**, **620**, **630** as described above while the illumination source **230** is activated and deactivated.

[0064] In some embodiments, the controller determines a signal to noise ratio from the charge is accumulated in charge storage bins **615**, **625**, **635** and compares the determined signal to noise ratio to a threshold. If the determined signal to noise ratio is less than the threshold, the controller

provides control signals to open and close transfer gates **610**, **620**, **630**, as further described above, until the signal to noise ratio determined from the charge accumulated in charge storage bins **615**, **625**, **635** equals or exceeds the threshold. If the determined signal to noise ratio equals or exceeds the threshold, the controller combines the charge stored in each of charge storage bin **615**, **625**, **635** to determine an intensity of light from the illumination source **230** captured by the pixel **600** and determines a depth of a location within the local area surrounding the DCA **120** from which the pixel **600** captured light from the illumination source **230**, as further described above in conjunction with FIGS. **4** and **5**. Accumulating charge in a single charge storage bin **615**, **625**, **635** coupled to the photodiode **605** by an open transfer gate **610**, **620**, **630** limits accumulation of background noise caused by the photodiode **605** capturing light from sources other than the illumination source **230**, allowing the pixel **600** to have a higher signal to noise ratio than other techniques. Additionally, accumulating charge from the photodiode **605** in different charge storage bins **615**, **625**, **635** allows the pixel to multiplex phase shift determinations for the periodic illumination pattern captured by the pixel **600**, which reduces the number of images for the image capture device **225** to capture to determine the phase shift of the periodic illumination pattern captured by the pixel **600** and reduces an amount of time the pixel **600** captures light emitted from the illumination source.

[0065] Referring back to FIG. **6A**, the pixel **600** also includes a drain **645** coupled to the photodiode **605** via a shutter **640**. When the illumination source **230** is deactivated, the controller provides a control signal to the shutter **640** that causes the shutter **640** to open and couple the photodiode **605** to the drain **645**. Coupling the photodiode **605** to the drain **645** while the illumination source is deactivated discharges charge produced by the photodiode **605** from ambient light in the local area surrounding the DCA **120**. When the illumination source **230** is activated, the controller provides an alternative control signal to the shutter **640** that closes the shutter **640** to decouple the photodiode **605** from the drain **645**. Additionally, the shutter **640** may be configured to open if a charge accumulated by the photodiode **605** from captured light equals or exceeds a threshold value, allowing charge accumulated by the photodiode **605** to be removed via the drain **604**, preventing the photodiode **605** from saturating and preventing charge accumulated by the photodiode **605** from being transferred into adjacent pixels **600**. The shutter **640** is configured to couple the photodiode **605** to the drain **645** until the charge accumulated by the photodiode **605** is less than the threshold or is at least a threshold amount below the threshold in some embodiments.

[0066] However, in other embodiments, different control signals regulate operation of the pixel **600** shown in FIG. **6A**. For example, the illumination source **230** is activated and remains activated, while different transfer gates **610**, **620**, **630** are activated at different times, so charge is accumulated in different bins **615**, **625**, **635** at different times. For example, during a time interval, the illumination source **230** remains activated and emitting the periodic illumination pattern, and control signals alternately activate transfer gates **610**, **620**, **630** during different time periods, so charge accumulated by the photodiode **605** is alternately transferred into bins **615**, **625**, **635**, respectively, during the time interval. As an example, during a first time period while

the illumination source **230** is activated, transfer gate **610** is activated and transfer gates **620**, **630** are closed, so charge accumulated by the photodiode **605** is transferred into bin **615**. During a second time period while the illumination source **230** remains activated, transfer gate **620** is activated and transfer gates **610**, **630** are closed, so charge accumulated by the photodiode **605** is transferred into bin **625**. Similarly, During a third time period while the illumination source **230** remains activated, transfer gate **630** is activated and transfer gates **610**, **620** are closed, so charge accumulated by the photodiode **605** is transferred into bin **635**. The different transfer gates **610**, **620**, **630** may alternately be activated as described above during a time interval while the illumination source **230** is emitting the periodic illumination pattern.

[0067] In other embodiments, relative timing between control signals activating the illumination source **230** and controls activating transfer gates **610**, **620**, **630** may differ. For example, a control signal activates a transfer gate **610**, **620**, **630** so the transfer gate **610**, **620**, **630** is active for at least a portion of a time while the illumination source **230** is active and emitting the periodic illumination pattern. As another example, control signals activating a transfer gate **610**, **620**, **630** are received by a transfer gate **610**, **620**, **630** after the illumination source **230** has been deactivated for a specific amount of time, adding a delay between deactivation of the illumination source **230** and activation of a transfer gate **610**, **620**, **630**. However, the preceding are merely examples, and the pixel **600** may be operated in any suitable manner in different embodiments.

[0068] FIG. **7** is another example of control signals regulating operation of the pixel **600** shown in FIG. **6A**. In the example of FIG. **7**, each transfer gate **610**, **620**, **630** is activated in a sequence separated by a fixed drain time. For purposes of illustration, FIG. **7** indicates times when the illumination source **230** emits light. As illustrated in FIG. **7** an illumination source **230**, further described above in conjunction with FIGS. **3** and **4**, emits pulses of light during a time interval when one of transfer gate **610**, transfer gate **620**, or transfer gate **630** is open. In the example shown by FIG. **7**, the illumination source **230** emits pulses of light synchronized with opening of each transfer gate **610**, **620**, **630**. As shown in FIG. **7**, during a time interval when the illumination source **230** emits pulse of light **710**, transfer gate **610** is open and transfer gate **620** and transfer gate **630** are closed; hence, charge accumulated when pulse of light **710** is emitted is transferred into charge storage bin **615** via transfer gate **610**. Similarly, during an additional time interval when the illumination source **230** emits pulse of light **720**, transfer gate **620** is open, while transfer gate **610** and transfer gate **630** are closed; therefore, charge accumulated during emission of pulse of light **720** is transferred into charge storage bin **625** via transfer gate **620**. During a further time interval, illumination source **230** emits pulse of light **730** and transfer gate **630** is open, while and transfer gate **610** and transfer gate **620** are closed; thus, charge accumulated when pulse of light **730** is emitted is transferred into charge storage bin **635** via transfer gate **630**. In various embodiments, opening of transfer gate **610**, transfer gate **620**, and transfer gate **630** is synchronized with emission of pulse of light **710**, pulse of light **720**, and pulse of light **730**, respectively.

[0069] In the example of FIG. **7**, the shutter **645** is opened during intervals when the illumination source **230** is not

emitting pulse of light 710, pulse of light 720, or pulse of light 730. Opening the shutter 645 during intervals between opening of different transfer gates 610, 620, 630 removes ambient background light captured by the photodiode 605 during times when the illumination source 230 is not emitting light by transferring the captured ambient background light to the drain 640. In various embodiments, the shutter 645 is opened within a threshold time interval from a time when the illumination source 230 stops emitting pulse of light 710, pulse of light 720, or pulse of light 730. For example, the shutter 645 is open from within a threshold time interval from a time when the illumination source 230 stops emitting pulse of light 710 until a time when the illumination source 230 starts emitting pulse of light 720 (or until a time within the threshold time interval when the illumination source 230 starts emitting pulse of light 720). Similarly, shutter 645 may be open from a time within the threshold time interval from a time when the illumination source 230 stops emitting pulse of light 730 until a time when the illumination source 230 starts emitting pulse of light 720 (or until a time within the threshold time interval when the illumination source 230 starts emitting pulse of light 720). Similarly, shutter 645 may be open from a time within the threshold time interval from a time when the illumination source 230 stops emitting pulse of light 730 until a time when the illumination source 230 starts emitting pulse of light 730; the shutter 645 may further be open from a time that is within the threshold time interval from a time when the illumination source 230 stops emitting pulse of light 730 until a time when the illumination source 230 starts emitting another pulse of light (or within a threshold time interval from the time when the illumination source 230 starts emitting another pulse of light). However, in other embodiments, the pixel 600 does not include the shutter 640 and the drain 645.

[0070] While FIG. 7 shows example timing of illumination of pulses of light, opening of transfer gate 610, transfer gate 620, transfer gate 630, and the shutter 640, different implementations may have different timings. For example, the shutter 640 may be opened for a longer or a shorter time interval than shown in FIG. 7; in an embodiment, the shutter 640 is opened for a fraction of an amount of time between emission of consecutive pulses of light by the illumination source 230 (e.g., for 10% of a time between emission of consecutive pulses of light by the illumination source 230, for 50% of a time between emission of consecutive pulses of light by the illumination source 230). Alternatively, the shutter is opened for a specific amount of time between emission of consecutive pulses of light by the illumination source 230. In some embodiments, the shutter 640 may not be opened. Similarly, transfer gate 610, transfer gate 630, or transfer gate 640 may be opened for a longer or a shorter length of time than those shown in FIG. 7.

[0071] In some embodiments, the illumination source 230 emits a different pattern of light when different transfer gates 610, 620, 630 are open. For example, when transfer gate 610 is open, the illumination source 230 emits a pulse of light (e.g., pulse of light 710 in FIG. 7) having a first illumination pattern, emits a pulse of light (e.g., pulse of light 720 in FIG. 7) having a second illumination pattern when transfer gate 620 is open, and emits a pulse of light (e.g., pulse of light 730 in FIG. 7) having a third illumination pattern when transfer gate 630 is open. In various embodiments, the first illumination pattern, the second illumination pattern, and the third illumination pattern are different from each other. Accordingly, the illumination source 230 emits pulses of light having different illumination patterns during time intervals when different transfer gates 610, 620, 630 are open.

[0072] Additionally, in some embodiments, the illumination source 230 emits a variable number of pulses of light that are synchronized with opening of one of transfer gate 610, transfer gate 620, and transfer gate 630; the number of emitted pulses of light may be fixed or may dynamically vary (e.g., based on an auto-exposure mechanism). A different number of pulses of light may be synchronized with opening of different transfer gates 610, 620, 630 in some embodiments. For example, the illumination source 230 emits pulses of light synchronized with 1000 openings of transfer gate 610, emits pulses of light synchronized with 2000 openings of transfer gate 620, and emits pulses of light synchronized with 3000 openings of transfer gate 630; however, the illumination source 230 may emit any arbitrary number of pulses of light differing for opening of different transfer gates 610, 620, 630 and synchronized with opening of different transfer gates 610, 620, 630.

[0073] Alternatively, the illumination source 230 continuously emits a pattern of light instead of discrete pulses of light. The continuous pattern of light emitted by the illumination source slowly changes over time in various embodiments (e.g. as a fringe pattern that is moving continuously in time, as further described above in conjunction with FIGS. 3 and 4). When the illumination source 230 emits the continuous pattern of light, the transfer gates 610, 620, 630 and shutter 640 are opened as described in conjunction with FIG. 7, so the continuous pattern of light is integrated over a fixed discrete time. In such a scenario, the emitted illumination pattern is configured to return to a previously emitted pattern over a specified time interval; hence, the illumination pattern changes over time, but repeats with a specific frequency or period. Opening of each transfer gate 610, 620, 630 is also synchronized to repeat using the specified time interval, causing different transfer gates 610, 620, 630 to be opened when the same portion of the illumination pattern is emitted during different periods. For example, transfer gate 610 is synchronized to be opened when a specific portion of the continuous illumination pattern is emitted during each period of the continuous illumination pattern, so transfer gate 610 integrates the specific portion of the continuous illumination pattern during each period of the continuous illumination pattern. Similarly, transfer gate 620 is synchronized with the illumination source 230 so a different specific portion of the continuous illumination pattern is emitted during each period of the continuous illumination pattern, so transfer gate 620 integrates the different specific portion of the continuous illumination pattern during each period of the continuous illumination pattern.

[0074] The language used in the specification has been principally selected for readability and instructional purposes, and it may not have been selected to delineate or circumscribe the inventive subject matter. It is therefore intended that the scope of the patent rights be limited not by this detailed description, but rather by any claims that issue on an application based hereon. Accordingly, the disclosure of the embodiments is intended to be illustrative, but not limiting, of the scope of the patent rights.

1. A method comprising:
 - determining an illumination source is emitting a first periodic illumination pattern during a first time interval;
 - during the first time interval, communicating to a sensor a first control signal opening a first transfer gate cou-

- pling a photodiode of a pixel to a first charge storage bin and other control signals closing other transfer gates coupling the photodiode of the pixel to other charge storage bins apart from the first charge storage bin;
- determining the illumination source is emitting a second periodic illumination pattern having a different spatial phase shift during a second time interval; and
- during the second time interval, communicating to the sensor a second control signal opening up a second transfer gate coupling the photodiode of the pixel to a second charge storage bin and other control signals closing other transfer gates coupling the photodiode of the pixel to other charge storage bins apart from the second charge storage bin.
- 2.** The method of claim **1**, further comprising:
communicating an additional control signal to the sensor that closes the first transfer gate to decouple the photodiode of the pixel to the first charge storage bin while other transfer gates coupled to the photodiode of the pixel remain closed within a threshold time interval from a time when the illumination source stopped emitting the first periodic illumination pattern.
- 3.** The method of claim **2**, further comprising:
determining an additional time interval when the illumination source is emitting the first periodic illumination pattern; and
communicating an alternative control signal to the sensor opening an additional transfer gate to couple the photodiode of the pixel to an additional charge storage bin while the first transfer gate and other transfer gates coupled to the photodiode of the pixel remain closed in response to determining the illumination source is emitting the first periodic illumination pattern during the additional time interval.
- 4.** The method of claim **3**, further comprising:
communicating a further control signal to the sensor closing the additional transfer gate to decouple the photodiode of the pixel to the additional charge storage bin while the first transfer gate and other transfer gates coupled to the photodiode of the pixel remain closed within the threshold time interval from the time when the illumination source stopped emitting the first periodic illumination pattern.
- 5.** The method of claim **3**, further comprising:
determining an alternative time interval when the illumination source is emitting the first periodic illumination pattern; and
communicating a further control signal to the sensor opening an alternative transfer gate to couple the photodiode of the pixel to an alternative charge storage bin while the first transfer gate, the additional transfer gate, and other transfer gates coupled to the photodiode of the pixel remain closed in response to determining the illumination source is emitting the first periodic illumination pattern during the alternative time interval.
- 6.** The method of claim **1**, wherein each pixel further comprises a drain coupled to the photodiode by a shutter.
- 7.** The method of claim **6**, further comprising:
providing a signal to the sensor opening the shutter for charge accumulated by the photodiode to be directed to the drain within a threshold time interval from a time when the illumination source stopped emitting the first periodic illumination pattern.
- 8.** The method of claim **1**, further comprising:
communicating control signals to the sensor opening different transfer gates at different times corresponding to emission of the first periodic illumination pattern by the illumination source.
- 9.** The method of claim **1**, further comprising:
emitting different periodic illumination patterns at different times; and
communicating control signals to the sensor that open different transfer gates at times when the illumination source emits different periodic illumination patterns.
- 10.** The method of claim **1**, further comprising:
combining charge accumulated in each of a plurality of charge storage bins coupled to the photodiodes.
- 11.** A non-transitory computer-readable storage medium comprising stored instructions, the instructions when executed by a processor of a device, cause the device to:
determine an illumination source is emitting a first periodic illumination pattern during a first time interval;
during the first time interval, communicate to a sensor a first control signal opening a first transfer gate coupling a photodiode of a pixel to a first charge storage bin and other control signals closing other transfer gates coupling the photodiode of the pixel to other charge storage bins apart from the first charge storage bin;
determine the illumination source is emitting a second periodic illumination pattern having a different spatial phase shift during a second time interval; and
during the second time interval, communicate to the sensor a second control signal opening up a second transfer gate coupling the photodiode of the pixel to a second charge storage bin and other control signals closing other transfer gates coupling the photodiode of the pixel to other charge storage bins apart from the second charge storage bin.
- 12.** The non-transitory computer-readable storage medium of claim **11**, further comprising stored instructions that when executed cause the device to:
communicate an additional control signal to the sensor that closes the first transfer gate to decouple the photodiode of the pixel to the first charge storage bin while other transfer gates coupled to the photodiode of the pixel remain closed within a threshold time interval from a time when the illumination source stopped emitting the first periodic illumination pattern.
- 13.** The non-transitory computer-readable storage medium of claim **12**, further comprising stored instructions that when executed cause the device to:
determine an additional time interval when the illumination source is emitting the first periodic illumination pattern; and
communicate an alternative control signal to the sensor opening an additional transfer gate to couple the photodiode of the pixel to an additional charge storage bin while the first transfer gate and other transfer gates coupled to the photodiode of the pixel remain closed in response to determining the illumination source is emitting the first periodic illumination pattern during the additional time interval.
- 14.** The non-transitory computer-readable storage medium of claim **13**, further comprising stored instructions that when executed cause the device to:
communicate a further control signal to the sensor closing the additional transfer gate to decouple the photodiode

of the pixel to the additional charge storage bin while the first transfer gate and other transfer gates coupled to the photodiode of the pixel remain closed within the threshold time interval from the time when the illumination source stopped emitting the first periodic illumination pattern.

15. The non-transitory computer-readable storage medium of claim **13**, further comprising stored instructions that when executed cause the device to:

determine an alternative time interval when the illumination source is emitting the first periodic illumination pattern; and

communicate a further control signal to the sensor opening an alternative transfer gate to couple the photodiode of the pixel to an alternative charge storage bin while the first transfer gate, the additional transfer gate, and other transfer gates coupled to the photodiode of the pixel remain closed in response to determining the illumination source is emitting the first periodic illumination pattern during the alternative time interval.

16. The non-transitory computer-readable storage medium of claim **11**, wherein each pixel further comprises a drain coupled to the photodiode by a shutter.

17. The non-transitory computer-readable storage medium of claim **16**, further comprising stored instructions that when executed cause the device to:

provide a signal to the sensor opening the shutter for charge accumulated by the photodiode to be directed to the drain within a threshold time interval from a time when the illumination source stopped emitting the first periodic illumination pattern.

18. non-transitory computer-readable storage medium of claim **11**, further comprising stored instructions that when executed cause the device to:

communicate control signals to the sensor opening different transfer gates at different times corresponding to emission of the first periodic illumination pattern by the illumination source.

19. non-transitory computer-readable storage medium of claim **11**, further comprising stored instructions that when executed cause the device to:

emit different periodic illumination patterns at different times; and

communicate control signals to the sensor that open different transfer gates at times when the illumination source emits different periodic illumination patterns.

20. non-transitory computer-readable storage medium of claim **11**, further comprising stored instructions that when executed cause the device to:

combine charge accumulated in each of a plurality of charge storage bins coupled to the photodiodes.
