[57] ABSTRACT

A method for detection of a sequential data stream which can be performed without host computer intervention is disclosed featuring examination of a data record and channel program during read operations for signals indicative that the data is not part of a sequential data stream, for example, embedded seek instructions. If a particular sought for record does not contain such indications, the successive record or records may then be staged to a faster access memory device such as a solid-state cache. The invention is described in a plug-compatible, software-transparent configuration.

DETECTION OF SEQUENTIAL DATA STREAM FOR IMPROVEMENTS IN CACHE DATA STORAGE

FIELD OF THE INVENTION

This invention relates to the field of data storage and management. More particularly, the invention relates to a method for detecting whether a particular data set having been requested from long term storage by a host computer is likely to be part of a sequence of such sets to be called for.

BACKGROUND OF THE INVENTION

Modern data processing systems typically comprise a host computer, consisting of an arithmetic and logic unit and a main memory unit for containment of data and instructions presently being processed, and longterm storage means for storage of data and processing instructions at other times. The long-term storage 20 means is typically connected to the host computer by means of a channel. When the host desires a particular data set or record, it issues a command over the channel to the long-term storage means, which then reads the data, from whatever medium it is stored upon, e.g., 25 magnetic disk or tape memory media, over the channel into the main memory of the host. The substantial length of time required to retrieve data from long term storage limits the throughput or usage of the host computer. To minimize this loss of use of the host computer, 30 the host will typically issue a series of requests for data and then perform other tasks while the data is being retrieved from long term disk or tape memory. However, even when this "queueing" is performed there is substantial host computer computation time lost due to 35 the time required for accessing data. Accordingly, it has remained an unsolved problem in the art and it is an object of the present invention to improve host computer throughput by reducing queueing times.

It has been proposed in the prior art that such queue- 40 art. ing times be reduced by "staging" data surrounding all data which is the object of a "SEEK" command issued by a host from a disk or tape memory into a solid-state memory of much higher access speed. The solid-state memory is located external to the host, i.e., outboard of 45 the channel from the host. Thus when the host issues subsequent "READ" commands, the data sought may be already contained in the high speed solid-state memory and can be supplied to the host more or less instantaneously. However, if all data sets surrounding records 50 accessed by the host are read into a solid-state memory external to the host as described above, the problem of queueing is not entirely eliminated, as then the channel and director usage time consumed while data is read into cache memory is added to the actual latency time 55 required for the data set to be read from disk into the cache memory.

Moreover, it will be appreciated that there are generally two ways in which data is accessed by a host computer. All the data in a given data set may be called for 60 by the host at a given time, or the host may initiate a separate call for each portion of the data set as each is required. In the first case, addition of the cache memory to the system adds no performance improvement, as but a single latency time is required to satisfy each input-output request. In the second case, wherein each individual host instruction is part of a sequence of instructions typically directed to access successive portions of

a physical record such as a tape or disk drive, there is latency time for each call to access a portion of the data set. In this situation, the latency time can be reduced to that of a single access operation involving a single latency time, if successive portions of the data are read into the cache, as the subsequent requests can then be satisfied directly from solid-state memory without involving second and successive physical access operations. That is, if the data is cached in anticipation of a subsequent "SEEK" command it will be available immediately upon issuance of a "READ" command. Accordingly, it is desirable that means be provided for determining which data supplied to a host in response to input/output requests are likely to be part of a sequence of such requests such that only the sequential data called for in requests will be cached. In this way use of the cache will be optimized at no cost to non-sequential operations.

It would not, of course, be impossible for the host computer to issue a signal indicating whether or not a particular data set called for is part of a sequence of such sets. This would of course simplify the decision as to whether or not to "stage" the subsequent record from the long-term data storage means into a cache memory. However, present day computing systems of commercial importance (such as the IBM Corporation's line of computers) do not provide such a signal. Nor is it desirable to modify these computers, nor in particular their operating systems, in order to provide such a signal as such modifications are difficult to implement correctly and are not popular with computer users.

Accordingly, it is desirable to render the caching of data function more efficient by using improved means and methods to determine whether a particular data set sought by a host computer is part of a sequence of such sets (in which event the subsequent sets would be cached) while data which is not amenable to efficient caching is processed in the same manner as in the prior

It is a further object of the invention to provide a system in which sequential data sets can be cached so as to improve throughput of a host computer system, without requiring modification to the host.

Yet another object of the invention is to provide a means and method for detecting whether or not a data record is part of a sequence of such records, wherein the means and method operates using information contained within the data record itself, whereby implementation of the method of the invention is rendered simple and relatively inexpensive.

SUMMARY OF THE INVENTION

The present invention satisfies the needs of the art and the objects of the invention as noted above by examining each data record that is read from long-term data storage means by a host computer. Control signals contained in the data and the (conventional) channel program are used to provide indications that the record is not one of a sequence of records stored together on long-term storage means. If none of these indicators is found during the "retrieval" of a given record from long-term storage to a host computer, the succeeding record(s) are then cached. Upon the receipt of each successive "read request" from the host computer, the request is compared with a directory which keeps track of which records have been cached so that the host's request will be satisfied from the cache if possible. In a

particularly preferred embodiment, if a first record on a given disk track is read from the disk storage device into the host and no indicator that the first record is not part of a sequence of records on the given track is detected, then the remainder of the data on the given track is then 5 cached. If the data on the rest of the given track is then called for by the host computer, the track next succeeding the given track is then cached, again without host intervention, and so on.

BRIEF DESCRIPTION OF THE DRAWINGS

The invention will be better understood if reference is made to the accompanying drawings, in which:

FIG. 1 represents a simplified view of the system within which the invention forms a part; and

FIG. 2 represents a flowchart of the decision making process according to the invention.

DESCRIPTION OF THE PREFERRED **EMBODIMENTS**

As described above, the method of detection of a sequential data stream of the invention was designed in particular to operate within the cache memory buffered subsystem which is the subject of copending application Ser. No. 325,346 filed Nov. 27, 1981. The chief objec- 25 tive of the cache memory buffered system which is the subject of the copending application referred to above and of which the present invention forms a part is to save on latency time required to complete a "SEEK" instruction given by the host computer by reading data 30 into a faster access, typically solid-state, memory from a slower access, long-term magnetic storage device, in advance of the host actually calling for the data. In this way, if the cached record is then called for, a physical delay need not be undergone. Clearly, it is desirable that 35 only those records which, in fact, are portions of sequentially accessed sequences of records be staged to the solid-state memory or "cached". Otherwise, caching of data will have beneficial effects only when substantially all the records sought for are, in fact, sequen- 40 tial, e.g., on the order of 90%. This is not the case in typical commercial systems. Accordingly, it is required that some means be provided to detect which records are portions of sequences of records and to cache only those. The present invention relates to means for mak- 45 ing the determination.

As also discussed above, the invention is designed to operate in a cache buffered memory subsystem operating as a add-on to a pre-existing memory system which is plug-compatible with a host computer, in a preferred 50 embodiment with an IBM 370 Series machine operating under a typical IBM operating system. The broad layout of the system of the copending application referred to above is shown in FIG. 1. There, the host computer 10 passes commands and data over and receives data 55 from a channel interface indicated generally at 12. In the event that the data to be accessed is stored on a disk drive such as at 14, access commands are passed to a storage director 16 which converts it into a form suitable for controlling a control module 18 which actually 60 is conducted throughout the reading, while the actual controls the movement of the disk drives 14, e.g., the radial movement of the read/write heads with respect to the disks and the like. The system as thus far described is conventional. What is added by the invention of the copending application referred to above is a 65 additional decision-making carried out independent of cache memory subsystem indicated generally at 20 comprising a solid-state cache memory 22 and a cache manager 24 for determining which data is to be staged

into the cache memory 22 from the disks 14. It is accordingly the cache manager 24 which carries out the method of the present invention, which will now be described in detail.

When the host computer 10 seeks to obtain data from a disk storage system 14, it issues a well defined "SEEK" command over the channel 12, which is acted upon by the storage director to cause the control module 18 to access the data sought for. The data is then passed back through the control module 18 and the storage director 16 and over the channel interface 12 to the host 10. The actual reading and writing of data is performed under a channel program also defined by IBM, as is the channel interface itself, in a document 15 entitled "I/O Interface Channel to Control Unit", IBM Publication GA22-6974-4. As will be appreciated by those skilled in the art, this well defined protocol permits the data itself to contain additional instructions for further data reading and writing. For example, if a 20 given data set is stored at several different locations on disk, for example, on several different "cylinders", these being areas of data storage spaced at varying distances from the central axis of the disk stack, a "CYLINDER SEEK" command may be encountered during the reading of data. The control module and storage director then cause the head to access the new cylinder sought for and to continue the reading operation. Similar instructions include head seek commands. Thus, typically in the prior art the storage director will follow such "embedded" commands in addition to those received from the host. Similarly, the channel program processed by the storage director itself may contain such commands. Inasmuch as the system of the present invention is desirably "software transparent" to the host, i.e., requires no modification thereto, it continues to obey these instructions. However, it additionally comprises means for examining the data as it is read from the disks to the host, and the channel program's performance, for determining whether additional data should be staged from the disk to the cache after completion of the actual operation ordered by the host. Specifically, the cache manager 24 examines the data as it passes through the storage director 16 for commands such as those above. If it receives no indications that the data is not of sequential nature—these being defined more fully below— it then continues with the reading of all the data stored on a given track (i.e., an area of data storage on a single surface of a disk one full revolution long) into the cache. If the host then calls for the remainder of the track, the cache manager detects this and causes the next track to be similarly staged to the cache without host intervention, and so on. In this connection, note that the "next track" may not be physically adjacent to the last on the same disk surface. Depending on the organization of the disk system, the "next track" may be on an entirely different disk surface, though usually one located above or below the last in a stack of disks, so as to save on both seek and latency delay times.

Accordingly, examination of the data read to the host decision as to whether the following track should be staged is made at completion of the request; that is, at the end of performance of the conventional "channel program". The present invention therefore relates to the host by the cache controller 24. Specifically, the storage director 16 reports to the cache controller or manager 24 certain information or "statistics" which

enable the cache manager 24 to make decisions concerning the desirability of staging successive tracks. In a presently preferred embodiment, these statistics may include:

1. Was the first record on the track among the re- 5 cords processed?

2. Was the last record on the track among the records processed?

3. Was the end of file record among the records processed?

4. Was the channel program processed against the cache or direct to the disk storage device?

5. Were there cache or disk read errors encountered?

6. Was an embedded head or cylinder seek command encountered in the channel program?

7. Did a write command occur during the channel program?

8. How many records were processed in the track during the channel program? and

9. How long were the records processed?

As discussed above there are two basic types of decisions relating to stagings to be made following execution of the channel program. First, if the channel program was processed directly from the storage director to the disk drive, i.e., a non-cached record was read, the 25 question as to whether the remainder of the track should be staged into the cache arises. Future accesses would then be directed to the cache; that is, subsequent SEEKs are considered by the cache manager to see whether the record sought for by the host has previ- 30 ously been cached. The second question arises when the channel program was processed to the cache, that is, the data sought for by the channel program was found in the cache, and concerns whether it is desirable to "prestage" the entire next disk track into the cache. Of the 35 above statistics, the following disqualify data from being cached: errors, write commands, embedded seek commands, or "End of File" records. These are all counterindicators of the desirability of caching, as they indicate that the next record on the disk is not necessar- 40 ily part of the same program as that read.

FIG. 2 shows the decision making process in the form of a flowchart. The process shown would be undergone at the completion of each read operation. The examination of the statistics kept by the director to determine 45 whether any of the statistics disqualify the record from staging is performed first, as indicated at block 30 where "no stage" indicators are looked for. If there are such indicators the data is not staged as noted at 32. If there are no such indicators, the next question is whether the 50 previous access was directly from the disk to the host or whether the operation was from the cache to the host, as indicated at decision block 34. If the operation was from disk to host ("NO" answer to block 34) the data is then looked at to see whether both the first record on 55 the track was read and that more than one-half of the track remains to be read, as shown at 36. If both these conditions are true then the remainder of the track is staged, as noted at 38. Parenthetically, the reason why whether more than 1 of the track remains is considered 60 herein by reference is a complete "pseudocode" rendiis simply to insure that it is worthwhile to do the staging (i.e., read the remainder of the track into the cache) at this particular point. Returning to consideration of block 34, if the previous operation was from the cache to the host, then the question is whether prestage of the 65 next track is desirable. At decision block 40 the question is whether prestage is allowed for records stored on a particular disk device. This allows the system designer

to prevent the data stored on certain disk devices from being cached, i.e., allows him to save certain disks for data he knows will be random. For example, so-called "fixed head disks" which typically have less latency time than movable head disk drives would ordinarily not be used for sequential data sets. If prestage is not allowed, then the decision is made simply not to stage. If prestage is permitted, the cache manager 24 (FIG. 1) then determines if prestage is desirable. For example, 10 the decision might consider whether both the last record of the track was read and whether there were at least 3 access commands to the track as noted at 42. Both these conditions are to be satisifed before prestaging is accomplished. If so, prestage is undergone, at 44, by reading the next track into the cache. If the last record of the track has not been read, clearly prestaging is inappropriate. Even if this condition is fulfilled, if there were less than three access commands per track, the records are evidently quite long and prestaging is 20 not required to reduce operating time lost to latency to a workable minimum. Similarly, the manager might look at the length of the record requested in a given request, and stage more than the remainder of the track, or more than a single following track, if it appears that one or more subsequent similar requests will not otherwise be satisfied by the data staged to the cache.

The flowchart above will be appreciated by those skilled in the art as one designed to operare as a subprogram within a cache manager control program. In particular, the method of the invention as described above is designed to operate within the Model 8880 disk controller available from Storage Technology Corporation, the assignee of the present invention. Indeed, the present invention together with that described in the copending application referred to and incorporated by reference above, is field installable in this disk drive controller in a reasonable time and at relatively modest cost. Accordingly, the decision-making sequence shown in FIG. 2 is configured as a subprogram undergone every time a channel program is executed. There are numerous other ways in which it would be possible to implement the method of the invention. For example, staging could only be considered where the record most recently read began a track and prestaging could only be considered at the end of a track. Those skilled in the art will recognize that numerous other expedients are possible.

In a presently preferred embodiment, the decisionmaking capacity of the invention is embodied in microcode permanently written on a floppy disk physically carried within the storage director container and written to solid-state random-access memory each time the director is turned on. This is operatively connected to a preexisting storage director processor for performing the cache manager function. Use of, e.g., a Zilog Z8000 microprocessor is envisioned as a possible substitute in an updated director, although again those skilled in the art will recognize that there are numerous alternatives.

Attached hereto as Appendix A and incorporated tion of the method of the invention. This pseudocode includes both actual microcode instructions and documentary notes so as to enable one other than the original programmer to understand the program. Appendix A describes a microcode module entitled "End-Channel Program Processing". It begins with a zeneral description of the program function, and with operational descriptions including the bits which are required from

the storage director for its operation, definition of the various subroutines and of the various registers required. The bulk of the program begins at line 01770 (page 2.163) and comprises actual microcode instructions as at lines 02730 through 02840 preceded by En- 5 glish language explanatory matter describing subject matter of the decision made by the following microcode, e.g., as at lines 02630 through 02720. The decision blocks shown in FIG. 2 are contained in modules of the microcode of Appendix 1. For example, the stage deter- 10 mination decision-making flowchart which is described above in connection with FIG. 2 runs from pages 2.169 through 2.176 of Appendix 1. Of this, for example, the decision represented by box 30 in FIG. 2 is shown in English language form at lines 02060 through 02150 and 15 in microcode at lines 02160 through 02390.

The remainder of the microcode and functional description attached will be of use in understanding of various other functions of the cache manager, for example, deallocation of inactive frames is described in a 20 submodule following that referring to the stage determination just discussed. "Deallocation" refers to the process whereby areas of the solid-state memory of the cache are selected for reuse, i.e., it is determined by this sub-module that the data stored in a portion of the cache 25 ways ir will no longer be sought by the host. For example, upon the host's writing to an area on a disk, the contents of which were previously cached, the data stored in the cache is clearly no longer valid and hence that area of the cache is deallocated and returned to the pool of 30 claims.

vacant storage locations, to which the cache manager may elect to assign data to be staged.

Those skilled in the art given the thus incorporated documentation of the End-Channel Program would have no difficulty in practicing the process of the invention.

Other copending applications which may be of relevance in understanding the present invention are incorporated herein by reference, including copending Ser. No. 325,351 filed Nov. 27, 1981 which discusses the organization of the memory space comprised in the solid-state cache memory 22. Error management and recovery functions performed by the cache manager are discussed in copending Ser. No. 325,287 filed Nov. 27, 1981 incorporated herein by reference. Also relevant is copending application Ser. No. 325,288 filed Nov. 27, 1981 incorporated herein by reference which discusses how precise correspondence between storage locations on the disk devices and the cache is maintained.

Those skilled in the art will recognize that there has been described a method for determining the sequential nature of a disk record which satisfies the needs of the art and objects of the invention discussed above. Moreover, it will be recognized that there are numerous ways in which the method of the invention can be embodied and improved upon and that therefore the above disclosure should not be considered as a limitation on the invention but merely as exemplary thereof. The invention is more properly defined by the following claims.

APPENDIX A

DESCRIPTION:

The END CHANNEL PROGRAM command provides the Cache Manager with a summary of the events occurring during the Channel Program. Information regarding errors from either the Cache or the DASD as well as access monitoring statistics is included. Additional flags are included which indicate the following: the operation started on the Cache. the operation started on DASD, an imbedded seek was encountered. a track switching operation occurred, or a write operation occurred.

The DASD operation flag indicates that the Cache Director, following the DIRECTORY SEARCH command, started the track field transfers on DASD versus on the Cache.

Whenever an imbedded cylinder seek (DASD seek or cylinder seek commands) is encountered, the END CHANNEL PROGRAM command is issued lamediately with the imbedded cylinder seek flag set. All statistics and last seek information is updated immediately and the frame in the Cache Directory is invalidated.

If the write flag is set and the processing was to the Cache (ie. not DASD OPERATION'), the frame corresponding to DID.C.C.H is invalidated.

When the track switch flag is set along with the write flag, the Cache Manager invalidates any frame containing a track with an address between the original address that was used for the directory search, and the address currently given (last seek address) in the END CHANNEL PROGRAM command. Thus any track that the write could have occurred to is invalidated and integrity is preserved.

The Update Seek Only flag is indicated when a channel program is received which contains only control commands (not reads/searches). The Recalibrate command is an example of a control command. The Cache Manager updates the last seek address stored in the Cache Manager.

DASD read error is returned in the case of No Record Found, Data Check, or Track Overrun conditions. The frame in the Cache Directory is invalidated.

If Cache read checks are indicated, the Cache Manager marks the indicated frame unusable in the Cache Directory.

If the Cache Manager determines that it would be profitable to stage this track. based on access monitoring and customer indications, it returns 'READ STAGE PARMS' status which causes the STAGE operation to be initiated.

    FUNCTIONAL DESCRIPTION
                                                                           00100
                                                                           00110
    The Update Statistics routing updates the Device Statistics Table.
                                                                           00120
    One of three event counters is incremented, depending on how the
                                                                           00130
    channel program was satisfied. The three counters are:
                                                                           00140
                                                                           00150
    READ CHANNEL PROGRAM SATISFIED THROUGH CACHE -- The channel program +
                                                                           00160
    was satisfied entirely through the cache.
                                                                           00170
                                                                           00180
    SWITCH TO DASD DUE TO WRITE -- The channel program started out on
                                                                           00190
    the cache but was switched to DASD because a write command was
                                                                           00200
    rece ived.
                                                                           00210
                                                                           00220
    TARGET TRACK NOT FOUND IN CACHE -- The target track was not in the
                                                                           00230
    cache so the channel program was satisfied entirely through DASD.
                                                                           00240

   FUNCTIONAL DESCRIPTION
                                                                          00110
                                                                          00120
  The Stage Determination routine is responsible for the decision
                                                                          00130
   on whether or not to stage a track, based on Information
  contained in the End Channel Program command. The module must
                                                                          00140
                                                                          00150
   decide whether or not to Stage the track if the channel program
                                                                          00160
   was executed on DASD, or whether or not to prestage the next
                                                                          00170
   track if it was executed on the Cache.
                                                                          00180
                                                                          00190
   The: following tasks are included in Stage Determination:
                                                                          00200
                                                                          00210
   - Check for no read errors
```

```
- Check for no writes in channel program
                                                                          00220
- Check for no imbedded cylinder seeks/track switch/imbed head seek +
                                                                          00230
- Check for no EDF indication
                                                                          00240
- Check for don't cache fixed head flag and fixed head cylinder
                                                                          00250
- Check for record one and >= 3/4 of track remaining unread as well *
                                                                          00260
    as on DASD for stage?
                                                                           00270
- Check for prestage indications
                                                                          00280
- Set up parameters for read stage parameters command
                                                                           00290
- Set 'read stage parameters data' valid flag
                                                                           00300
- Set 'prestage' flag if prestaging indicated
                                                                           00310
- Return stage/prestage/no stage indication
                                                                           00320
                                                                           00330
DPERATIONAL DESCRIPTION
                                                                           00340
                                                                           00350
The following algorithm is used in Stage Determination: First
                                                                           00360
the End Channel Program command is checked for any no staging
                                                                          00370
indicators which are: 'writes occurred', 'imbedded cylinder seek'
                                                                          00380
'track switch', 'EDF seen', 'cache read error', 'DASD read
                                                                           00390
error'. or 'imbedded head seek'. Any of these indications
                                                                          00400
prevent staging. Also, if the track indicated is a fixed head track +
                                                                          00410
and "don't cache fixed heads" was indicated for this device at
                                                                           00420
configuration time, no staging will occur. +
                                                                           00430
Next, if the channel program was executed on
                                                                          00440
the Cache. a prestaging decision must be made. The decision to
                                                                          00450
prestage is made only if the last record on the track was read,
                                                                           00460
prestaging is allowed on this DID, and at least three accesses
                                                                           00470
to the current track were made.
                                                                           00480
If the channel program executed on DASD, then the decision to
                                                                           00490
stage must be made. If the first record on the track was read,
                                                                          00500
and at least three-forths of the track still remains, then the
                                                                          00510
decision to stage is made. (see the diagram on next page)
                                                                          00520
                                                                          00530

#### We claim:

- 1. A method for increasing efficiency of operation of a computer system of the class comprising:
  - a host computer including an arithmetic and logic 30 unit and main memory means; and
  - a data storage unit comprising a long-term magnetic data storage means, a solid-state caching memory means and a cache manager means,
  - said data storage unit being connected to said host 35 computer by a channel, said channel comprising means for communication of commands and data between said host computer and said data storage unit, the commands output by the host to the data storage unit in calling for data not including an 40 indication of whether data called-for is part of a sequence of such requests;
  - said method comprising the following steps, performed by said data storage unit solely under conchannel and said host computer:
  - examining the data called for by the host from the long-term magnetic memory means;
  - determining if the called-for data contains indicators indicating that the called-for data is not part of a 50 of: sequential data stream;
  - staging data not called for by said host computer to said cache memory means upon determination that said called-for data does not contain said indicators, said not called-for data staged to said cache 55 memory being stored on said long-term magnetic storage media in a predetermined physical relationship to said called-for data; and
  - avoiding staging data to said cache memory means upon determination that said called-for data con- 60 tains indicators that the called-for data is not part of a sequential data stream.
- 2. The method of claim 1 wherein said indicators comprise commands contained within said called-for data directing additional data to be read from locations 65 other than those disposed in said predetermined physical relationship to said called-for data on said long-term magnetic storage media.

- 3. The method of claim 1 wherein said data is stored on disk drive media organized into logical tracks and said staging is only performed when said indicators are not present and when said previously called-for data includes the starting portion of one of said logical tracks.
- 4. The apparatus of claim 1 wherein said long-term magnetic data storage means comprise disk drive means wherein data is stored on concentric tracks on disks, and said staging is performed with respect to an entire track at a time, successive tracks being staged to said cache as previously staged tracks are called for by said host.
- 5. Method for improving the efficiency of a data processing system of the type comprising a host computer connected via channel means to a memory system comprising a solid-state cache memory means and longterm data storage means, said host being adapted to trol of said cache manager, and external to said 45 issue commands calling for specific data records stored on said long-term storage means, said commands not including an indication of whether a particular request is one of a group of requests for data stored sequentially on said long-term storage means, comprising the steps
  - examining each individual host originated command calling for a particular data record and the contents of the solid-state cache memory means to determine whether the data thus called for is stored in said solid-state memory means external to said channel, and, if said data is stored in said solid-state memory means, transmitting said data to said host; if said data is not stored in said solid-state memory means, accessing said data on said long-term data storage means and passing it over said channel

means to said host, and examining said data passed

from said long-term data storage means to said host

in order to determine whether said called-for re-

cord is one of a sequence of such records; and if said determination indicates that said called-for record may be one of such a sequence, determining the next record in said sequence and reading said next record from said long-term storage means into said solid-state memory means in anticipation of said next record being subsequently called for by said host.

6. The method of claim 5 wherein the determination that a given record is one of a sequence is accomplished by examination of said record for indicators signaling that said data is not part of such a sequence.

- 7. The method of claim 6 wherein said long-term data storage means comprises magnetic disk drive means, said disks being organized into tracks, said indicators signaling that a given record is not part of a sequence of such records comprising commands instructing that records not on the same track of the same disk be supplied to said host.
- 8. The method of claim 5 wherein said records are stored on long-term storage means, said long-term storage means comprising disk drive means adapted to store data organized into tracks, said data being read from said long-term storage means into said solid-state memory means track by track.

9. A method of control of storage of digital data in storage means comprising:

long-term magnetic storage means;

faster access solid-state cache memory means; and controller means;

said method comprising the steps of:

examining the sequence of commands output by a host computer in order to access data required, said commands not including an indication of whether said data required is part of a sequential data stream, and the data accessed by the host computer, for indicators that said data is not part of a sequential data stream;

staging a quantity of additional data to said cache memory means where said indicators are not present, in anticipation of said additional data being subsequently called for by said host computer; and

avoiding staging additional data to said cache means where said indicators are present.

10. The method of claim 9 wherein said examining step comprises the step of determining whether said sequence of commands includes instructions to read other data not stored sequentially on said long-term storage means with respect to said data required.

11. Apparatus for storage and retrieval of digital data for connection to a host computer of the type outputting commands for retrieval of data, said commands not including explicit indication of whether a particular data request is one of a sequence of requests for sequential portions of a given data file, said apparatus comprising:

long-term data storage means; solid-state cache memory means; and cache controller means;

said cache controller means being adapted to examine commands output by said host in effectuating retrieval of data, and to examine said data for embedded commands, said controller being adapted to determine whether said commands indicate that a particular data request is likely not to be part of a sequence of such requests, and to stage additional data from said long-term memory means to said cache memory means if no such indicators are present in the processing of a particular data request, in anticipation of further requests for sequential portions of a given data record.

12. The apparatus of claim 11 wherein said long-term data storage means comprises magnetic disk drive storage means wherein said data stored on said disks is organized into logical tracks and said data is staged from said disk drives to said cache memory means in multiples of one track.
