[57] **ABSTRACT**

A hemostasis valve is provided for catheters or the like, comprising an elastomeric partition valve secured in a housing. A linear slit extends through the partition valve between the major faces thereof. By this invention, the slit defines a line at each major face, with the respective lines at the major faces being in non-alignment and thus defining an angle with respect to each other. The slit defines at least one generally helical slit section between the lines of the major faces, within the partition valve. Such a partition valve exhibits better sealing characteristics over a wide range of diameters of catheters, leads, or the like penetrating the partition valve, as well as other advantages.

## MEDICAL INSTRUMENT VALVE

### BACKGROUND OF THE INVENTION

Hemostasis valves are well-known, being currently used, for example, on catheters for performing percutaneous transluminal coronary angioplasty (PTCA) as well as angiographic procedures, for example where x-ray contrast fluid is inserted into the coronary artery. Hemostasis valves are also used to prevent the leakage of blood out of the ends of dilation and guidance catheters, to prevent the seepage of blood between the guide wire and the dilatation catheter, and also between the two catheters.

Numerous types of hemostasis valves are known, by way of example, see Stevens, U.S. Pat. No. 4,000,739, Matsumoto et al, U.S. Pat. No. 4,610,665, and Weinstein U.S. Pat. No. 4,626,245.

Hemostasis valves may also be employed for the introduction of other catheters into the circulatory system or elsewhere in a leak-proof manner. The valve may be carried by any catheter or sheath introducer, to permit an inner catheter, probe, or the like to be placed through the hemostasis valve to form a leak-proof seal and a port of entry.

In accordance with this invention, a hemostasis valve is provided which exhibits significantly improved tolerance for varying diameters of catheters, probes, leads or the like penetrating it without leakage or damage to the valve. Thus, one catheter or another item carrying such a hemostasis valve is capable of receiving catheters or the other items as mentioned above having a greater variation in diameter. Additionally, the valve of this invention exhibits improvements by reducing sliding resistance for elongated objects such as catheters as they pass through the valve, yet they still provide good resistance to dislodgement of such a catheter after it has been properly positioned. Similarly, reduced compression on the catheter or other elongated member is noted within the valve of this invention, permitting greater facility in the use of multi-lumen catheters, for example. Nevertheless, the hemostasis valve of this invention still exhibits excellent and even improved pressure handling capabilities, to prevent leakage under pressure, whether or not an elongated object is passing through the valve of this invention.

### DESCRIPTION OF THE INVENTION

This invention relates to a hemostasis valve, which may be used for preventing backflow of blood or other fluids through a catheter or the like, while permitting passage of a probe, an inner catheter, an electrical lead, or any other elongated member through the valve. As is conventional, the hemostasis valve comprises an elastomeric partition valve having opposed major faces, the partition valve being secured in a housing.

In accordance with this invention, a linear slit extends through the partition valve between the major faces thereof, the slit defining a line at each major face in which the respective lines at the opposed major faces define an angle to each other. Also, the slit through the partition valve defines at least one substantially helical slit section extending between the above described lines on the major faces, through the partition valve. Such a design of slit has been found to provide improved sealing characteristics over a wide range of catheter diameters (or diameters of other elongated members passing through the hemostasis valve). Additionally, a self com-

pensating lubricity is provided, possibly caused by a sliding "iris" effect inherent in the spiral design of the slit used in the hemostasis valve of this invention, to permit easy insertion and withdrawal of elongated members through the valve. Nevertheless, the structure provides sufficient gripping action so that elongated members are not easily dislodged by unintentional means.

Additionally, the design of slit in the valve of this invention provides reduced compression on multi-lumen catheters, as well as improved resistance to leakage under circumstances of high pressure. The valve of this invention is easily manufactured for significant improvements in the performance of hemostasis valves for the above reasons and others as well.

Preferably, the above described line at each major face of the partition valve defines a plurality of intersecting radii, typically three, the radii being preferably substantially equiangularly spaced to each other on each face. These radii define an angle with corresponding radii on the opposed major face, with the respective, corresponding, opposed radii on opposed major faces defining a plurality (typically three) of the helical slit sections between them, the helical slit sections being in generally coaxial relation to one another.

Typically, the respective lines or radii on the opposed major faces which are connected to each other by a helical slit section define an angle of 10 to 180 degrees or more. Preferably this angle is 30 to 90 degrees, most preferably about 60 degrees.

The housing and elastomeric partition may be of any conventional design in which the housing holds the elastomeric partition about its edges, so that the central portion of the major faces are exposed for access by a catheter, a probe, or the like for passage therethrough. A major distinction of the invention of this application lies in the nature and shape of the slit which extends through the elastomeric partition valve. The elastomeric partition valve may be a simple disc of natural or synthetic latex, or any other desired elastomer which generally has sufficient resilience, typically in the range of 30 to 50 Shore "A" Durometer. Interestingly, inherently good needle resealability may not necessarily be a critical characteristic for a good material used as the elastomeric partition valve in this invention. For example, silicone rubber, especially silicone rubber materials having an impregnated amount of free silicone fluid (e.g. dimethylpolysiloxane preferably present in an amount of 2 to 10 weight percent) may desirably be used, although such is not often used as a needle-resealable barrier. The free silicone fluid can act as a lubricant that facilitates the advantages of this invention. Other elastomers and other impregnated fluid lubricants may also be used.

As one manufactures the partition valve in accordance with this invention by cutting a slit through it, one rotates the cutting blade (or the valve) during the cutting process so that the blade at its entry point on one major face defines an angle with itself at its exits point on the other major face, to provide the desired helical slit as described above.

The cutting blade may be of the desired helical shape, being rotated as it cuts through the elastomeric partition valve, but straight blades, perpendicular to the plane of the partition valve, can also be easily used because of the elastomeric nature of the partition valve. Specifically, the shape of the blade at its cutting edge will be

identical to the shape of the slit at each major face. Thus, preferably, the blade may also comprise a plurality of intersecting radial edges, particularly three, intersecting substantially equiangularly spaced radial edges, to define the preferred slit pattern. Then, the radially edged blades pass through the elastomeric valve with rotation to form the desired angle between the lines or radii at each major face as described above. It is generally preferred for a slit having a cross section of chevron shape, or a shape of two to six substantially equiangularly spaced radii from a common origin, to be used. However, it is not mandatory for the radii to be equiangular in their spacing.

After the novel design of slit has been formed by cutting into the elastomeric partition valve of this invention, it may be mounted into a housing in conventional manner, carried if desired on a catheter or the like for use. See the above cited patents, as well as other known technology for conventional housing designs and the like.

### DESCRIPTION OF THE DRAWINGS

In the drawings,

FIG. 1 is a perspective view, with a portion cut away, of a catheter which carries the hemostasis valve of this invention.

FIG. 2 is an enlarged plan view of the hemostasis valve of this invention showing a preferred slit pattern in the elastomeric partition valve.

FIG. 3 is a perspective view of the elastomeric partition valve of FIG. 2, showing the slit pattern.

FIG. 4 is a transverse sectional view taken along line 4—4 of FIG. 2.

FIG. 5 is a perspective view of the elastomeric partition valve of this invention.

FIG. 6 is a partial perspective view of a device for cutting the preferred slit pattern into an elastomeric disc.

FIG. 7 is a sectional view taken along line 4—4 of FIG. 6.

### DESCRIPTION OF SPECIFIC EMBODIMENT

Referring to the drawings, FIG. 1 shows a catheter sheath introducer 10, adapted to receive an inner catheter 12 as shown for inserting into the vascular system of a patient. Catheter sheath introducer 10 is used to introduce a catheter into a blood vessel while preventing blood backflow along the outside surface of the catheter during procedures in which a catheter is inserted into the vessel. Current designs of catheter sheath introducers are typically limited to a narrow range of only one or two French sizes of inner catheter 12 for which they can provide effective entry and sealing, while permitting inner catheter 12 to remain lubricious by not removing too much lubricant from it. This situation is improved by the invention of the previously cited U.S. Pat. No. 4,626,245. However, in accordance with this invention, further improvements relating to size tolerance of the valve of this invention are provided, along with the other advantages as described above.

Catheter sheath introducer 10 defines outer tubular housing 14 which carries cannula portion 16 of catheter sheath introducer 10, positioned in attached, telescoping relation with tubular protrusion 18 of the housing. Side port 20 may be of conventional design, being adapted for telescoping connection with plastic tubing 22, for providing a saline solution for flushing the interior of housing 14 and tubing extension 16.

Housing 14 also carries self-sealing penetrable barrier as elastomeric partition valve 24, which may be made of an appropriate elastomeric material. For example, natural rubber latex is well-known for providing excellent resealing characteristics. However, silicone elastomers, fluoropolymers, polyurethane elastomers, or any other elastomeric material may be used, depending upon the performance parameters desired, especially when they carry an impregnating lubricating oil. Preferably an oil-impregnated silicone rubber of Durometer 40 may be used.

Housing 14 may comprise casing portions 26, 28 which are sealed together in telescopic relation and which peripherally capture penetrable barrier 24 between them as shown. Alternatively, casing portion 28 may be a screw cap, for adjustable compressive retention of elastomeric barrier 24. Annular ribs 30, 32 may be provided in each housing portion to provide more positive capture of the elastomeric portion 24.

Referring to FIGS. 2 thru 5, details of the slit design in partition valve 24 are disclosed. Specifically, the cross-sectional shape of slit 40 is of the shape of three, intersecting, substantially equiangularly spaced radii 42, 44, 46, spaced about origin line 48 by about 120 degrees, and defined on major face 50. Alternatively, with four equiangularly spaced radii, the included angle between each radius is 90 degrees. Six spaced radii may define included angles of 60 degrees. Two equiangularly spaced radii define an included angle with each other of 180 degrees, and thus define a single, straight line, for a simplified version of the invention of this application.

On major face 52, on the other side of partition valve 24, slit 40 defines a substantially identical cross-section of three, intersecting, substantially equiangularly spaced radii 54, 56, 58, with respective helical slit sections 60, 62, 64 defined between the respective radii on opposed faces 50, 52 through the material of partition valve 24. As stated before, such a slit can be provided by a knife of corresponding cross-sectional shape which may have angled, or helical blades if desired, and which may be rotated as the blades cut through partition valve 24. Specifically, the total angle of cutting rotation shown is about 60 degrees, so that each radius 42, 44, 46 on surface 50 defines an angle of about 60 degrees to each radius 54, 56, 58 on surface 52 of partition valve 24. Preferably, the angle of cutting rotation increases linearly as cutting progresses. For example, if the total cutting angle is 60 degrees, at one-quarter depth from surface 50 the blades have rotated 15 degrees; at one-half of the depth between surfaces 50 and 52 the blades have rotated 30 degrees, etc.

FIGS. 6 and 7 show apparatus for punching a slit in accordance with this invention into a partition valve 24. The silicone rubber disk (containing impregnated silicone oil) that is to become partition valve 24 may be mounted in a jig 60, or otherwise mounted between casing portions 26, 28 on a catheter or the like. Triple-finned blade 62 is brought against the disk, while rotating as shown. Blade 62 is advanced through the opposed, major faces 50, 52 of the disk, being rotated by about 60 degrees as it advances between faces 50, 52, to cut the desired slit. Then, blade 62 is withdrawn from the newly-formed partition valve 24.

Origin line 48, as well as helical slits 60, 62, 64, extend entirely through partition valve 24 in a manner contrary, for example, to the disclosure of U.S. Pat. No. 4,626,245. Thus, when a catheter 12 or other elongated member is passed through partition valve 24, it passes

easily, with great tolerance, as to deviation in diameter of catheter 12, yet with good sealing retention of partition valve 24 about catheter 12, exhibiting the advantages described above.

Valve disk 24 may, for example, be about 0.068 inch thick, with its other dimensions being of proportionate size. When compressed, as by retention in the housing, the radial lines of the slit on the major faces of the partition valve may form arcs even through the original, cut lines are straight, due to compressive forces in the elastomeric valve. It follows that the original, cut lines on the major faces may be originally curved, if desired.

In the selection of a desired cross-sectional shape for slit 40 of this invention, the resistance of valve disk 24 to leakage of pressurized fluids will tend to increase as the angle subtended by the helical slit sections increases. In other words, an angle of 180 degrees between corresponding lines on opposed faces of valve disk 24 (and that much twist provided to the respective helical slit sections) will tend to provide more sealing capability than a significantly lesser angle.

Similarly, the sealing power of valve disk 24 will tend to increase with a reduction in the number of radii present in the slit cross-section. A straight line slit can therefore provide excellent sealing, especially when the helical section present twists by 60 degrees or more.

The above has been offered for illustrative purposes only, and is not intended to limit the scope of the invention of this application, which is as defined in the claims below.

That which is claimed is:

1. A medical instrument comprising a housing, said housing including a valve for receiving and sealing and elongated member which penetrates said valve, said valve comprising an elastomeric partition member having a first face and a second opposed face and adapted for securement in a housing, the improvement comprising, in combination:

a slit extending through said valve between said first and second faces, said slit defining a first line on said first face and a second line on said second face, said first line and said second line having a similar configuration but being in non-alignment with each other with a generally helical slit section extending between said first line and said second line.

2. The medical instrument of claim 1 in which said first line comprises a first plurality of intersecting radii and said second line comprises a second plurality of intersecting radii, with said first plurality and said second plurality having a similar configuration but being in non-alignment with each other and with generally helical slit sections extending between said first plurality and said second plurality.

3. The medical instrument of claim 1 in which said partition member carries an impregnated lubricating oil.

4. The medical instrument of claim 1 in which said partition member comprises a one-piece unitary member formed of silicone rubber.

5. The medical instrument of claim 1 in which the included non-alignment angle is between 10 and 180 degrees.

6. The medical instrument of claim 1 in which the included non-alignment angle is essentially 60 degrees.

7. The medical instrument of claim 2 in which said first and second plurality each define three intersecting substantially equiangularly spaced radii.

8. The medical instrument of claim 2 in which said first plurality have an included angle between each radius of between 60 and 180 degrees.

9. A catheter sheath introducer including a housing, said housing including an elastomeric partition valve for receiving a catheter which penetrates said valve, said valve having a first major face and a generally parallel and opposing second major face, the improvement comprising, in combination:

a slit extending through said partition valve between said first and said second major faces, said slit defining a first plurality of intersecting lines on said first major face and a second plurality of intersecting lines on said second major face, said first plurality and said second plurality having a similar configuration but being in non-alignment with each other with generally helical slit sections extending between said first plurality and said second plurality, said helical slit sections having similar configurations to said first plurality and said second plurality in cross-sectional plane that is generally parallel to and is between said first and said second major faces.

10. A catheter sheath introducer as described in claim 9, in which the line at each major face defines three intersecting substantially equiangularly spaced radii.

11. A catheter sheath introducer as described in claim 10, in which said partition valve comprises a one-piece unitary member carrying an impregnating lubricating oil and being formed of silicone rubber.

12. A catheter sheath introducer comprising a housing, said housing including an elastomeric partition valve for receiving a catheter which penetrates said valve, said valve having a first major face and a second generally parallel and opposing second major face, the improvement comprising, in combination:

a generally Y-shaped slit extending through said partition valve between said first and said second major faces, said slit defining a first plurality of intersecting lines of said first major face and a second plurality of intersecting lines on said second major face, said first plurality and said second plurality having a similar configuration but being in non-alignment with each other with generally helical slit sections extending between said first plurality and said second plurality, said helical slit sections having similar configurations to said first plurality and said second plurality in each cross-sectional plane that is generally parallel to and is between said first and said second major faces.

13. A catheter sheath introducer as described in claim 12 in which the included nonalignment angle is 10 to 180 degrees.

14. A catheter sheath introducer as described in claim 12 in which said partition valve carries an impregnated lubricating oil.

15. A method for making an elastomeric partition valve for use in a housing, comprising the steps of:

positioning an elastomeric member having a first face and a second opposed face on a fixture for cutting; providing a cutting blade;

bringing the cutting blade into alignment with said first face;

providing relative rotation between the cutting blade and the elastomeric member so that the cutting blade progresses from said first face through said second face, with the total rotation having a total angle of rotation of less than 180 degrees, whereby

a slit is provided through the partition valve between said first and second faces, and with said slit defining a first line on said first face and a second line on said second face, said first line and said second line having a similar configuration but being in non-alignment with each other.

16. A method for making an elastomeric partition valve for use in a housing of a medical instrument, comprising the steps of:

- positioning an elastomeric member having a first face and a second, opposed face on a fixture for cutting;
- providing a cutting blade having three equiangularly spaced and radially extending cutting members;
- bringing the cutting blade into alignment with said first face;
- providing relative rotation between the cutting blade and the elastomeric member so that the cutting blade progresses from said first face to said second face, with the total rotation between said first face and said second face having a total angle of rotation of less than 180 degrees, whereby a slit is provided through the partition valve between said first and second faces, said slit defining a first plurality of intersecting lines on said first face and a second plurality of intersecting lines on said second face, said first plurality and said second plurality having a similar configuration but being in non-alignment with each other.

17. A medical instrument comprising a housing, said housing including a valve for receiving and sealing an elongated member which penetrates said valve, said valve comprising an elastomeric partition member having opposed major faces and secured in a housing, the improvement comprising, in combination:

- a slit extending through said partition valve between the major faces thereof, the slit defining a line at each major face, the respective lines at said opposed major faces defining an angle to each other, said slit defining at least one generally helical slit section between said lines on the major faces and within said partition valve.

18. The medical instrument of claim 17 in which the line at each major face defines a plurality of intersecting radii, said radii on one major face being non-aligned

with the radii on the other major face and defining an angle to each other between the major faces, the respective, corresponding, opposed radii defining a plurality of said helical slit sections between them, said slit sections being in coaxial relation to each other.

19. The medical instrument of claim 18 in which the line at each major face defines three, intersecting, substantially equiangularly spaced radii.

20. The medical instrument of claim 18 in which said angle is 10 to 180 degrees.

21. The medical instrument of claim 20 in which said angle is 30 to 90 degrees.

22. The medical instrument of claim 18 in which said partition valve carries an impregnated lubricating oil.

23. The medical instrument of claim 22 in which said partition valve is made of silicone rubber.

24. A medical instrument comprising a housing, said housing including a valve for receiving and sealing an elongated member which penetrates said valve, said valve comprising an elastomeric partition valve having opposed major faces and secured in a housing, the improvement comprising, in combination:

- a slit extending through said partition valve between the major faces thereof,
- the slit defining, at each opposed, major face, a plurality of intersecting, substantially equiangularly spaced radii, the respective, individual radii on said opposed faces defining an angle of 10 to 180 degrees with each other, the respective, corresponding, angularly related radii on said opposed major faces respectively defining a plurality of helical slit sections between them and within said partition valve, said helical slit sections being in coaxial relation to each other.

25. The medical instrument valve of claim 24 in which the angle of respective radii on said opposed major faces is 30 to 90 degrees.

26. The medical instrument valve of claim 24 in which said partition valve carries an impregnated lubricating oil.

27. The medical instrument valve claim 24 in which said partition valve is made of silicone rubber.
