[57] ABSTRACT

A cassette for the acceptance of medical instruments, and preferably dental instruments, to enable a hygienic treatment of the instruments when the cassette is placed into a chamber of an apparatus that is capable of being closed pressure-tight. The cassette contains at least one adapter for holding at least one instrument. The adapter will have line channels for the delivery of treatment agents to the interior of the instrument and the adapter can contain a control valve that will close the line channels given an adapter not occupied with an instrument.

FIG 1

FIG 2

FIG 5

FIG 6

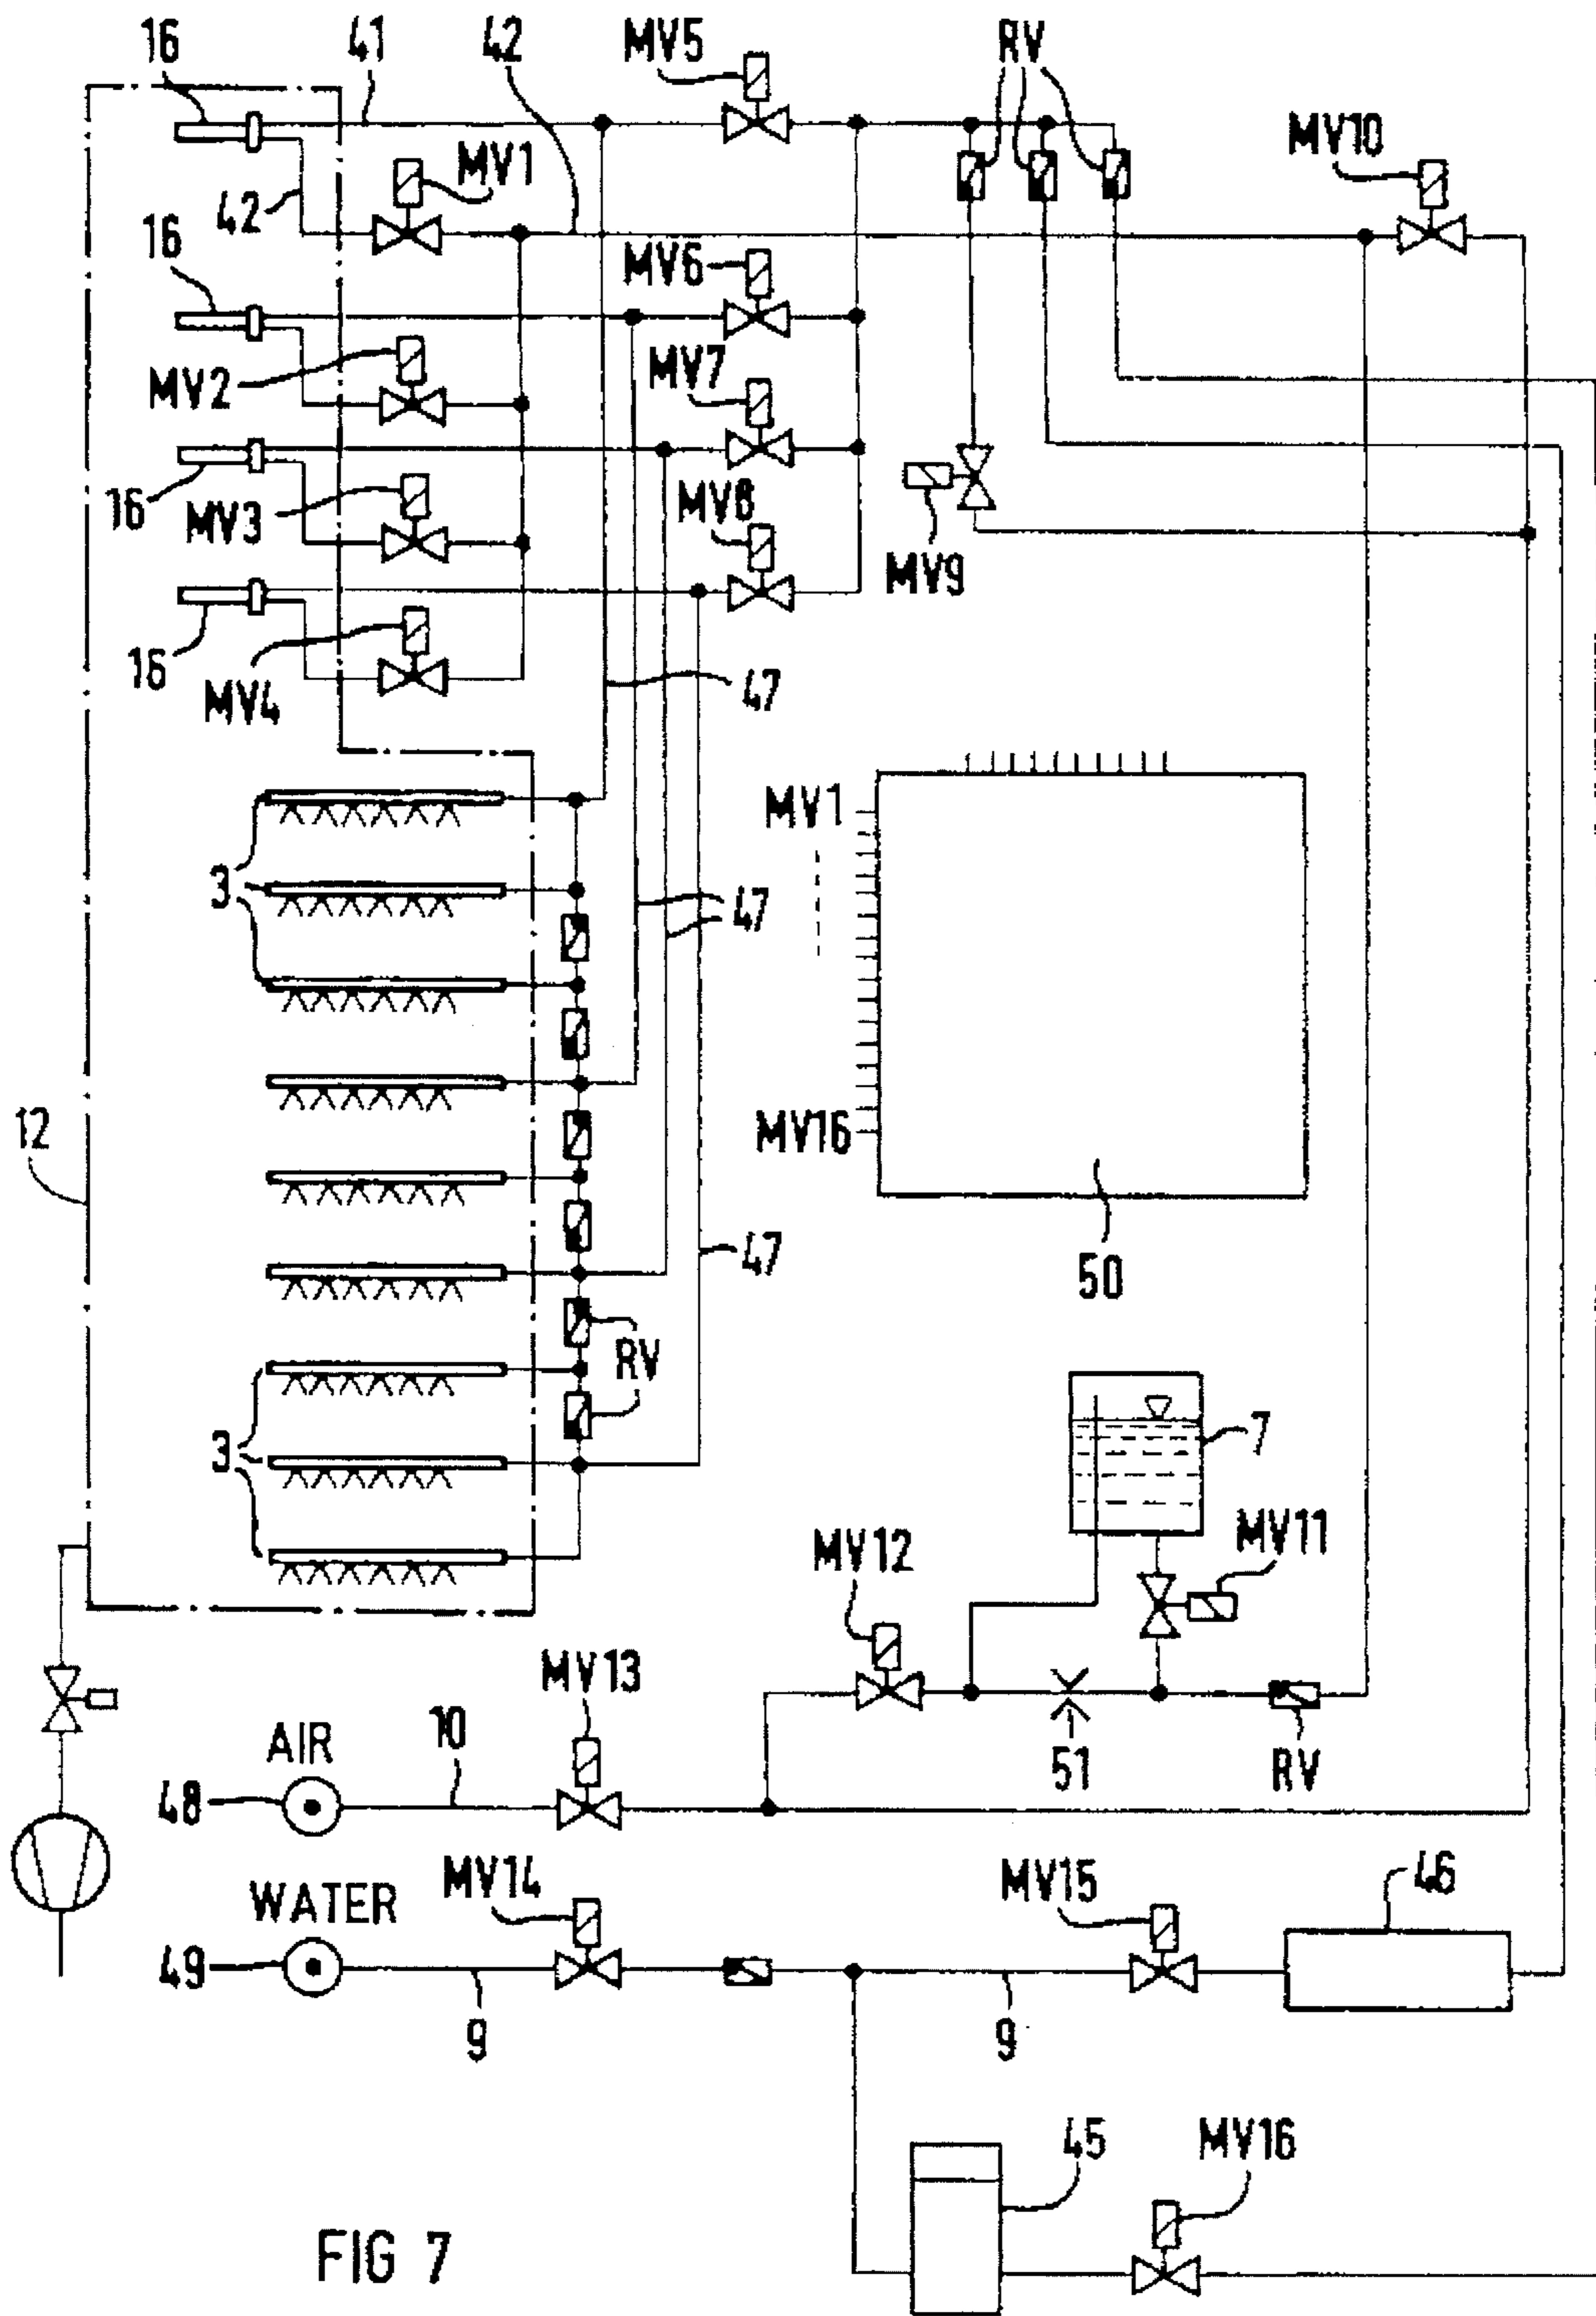

FIG 7

FIG. 8

CASSETTE FOR TREATING MEDICAL INSTRUMENTS

BACKGROUND OF THE INVENTION

The present invention is directed to a cassette for the acceptance of medical instruments, such as dental instruments so that they may be hygienically treated. To subject the instruments in the cassette to the treatment, the cassette is placed into a pressure-tight closable chamber of an apparatus.

U.S. Pat. No. 5,271,893, whose disclosure is incorporated herein by reference thereto and which is a continuation of an application which was the basis for European 0 429 960, discloses a cassette which receives instruments and is inserted into a chamber of an apparatus which injects treatment fluid into the cassette for treating instruments disposed therein. The cassette of the patent is constructed of two parts when the instruments are deposited on a grating in the lower cassette half. The cassette is then closed with the upper half and placed in a sterilizer.

The instruments can only be subjected to a sterilization with the known cassette, whereby it is mainly only the exterior surface of the instruments that are sterilized by the hot steam. With this cassette, a treatment of instruments, particularly of their internal parts or cavities, does not occur beyond the contact of hot steam on the outer surfaces of the instrument.

SUMMARY OF THE INVENTION

The object of the present invention is to provide an improved cassette for use in a treatment apparatus for treating medical instruments, such as dental instruments.

To accomplish these goals, the invention is directed to an improvement in a cassette for the acceptance of medical instruments, particularly dental instruments for the purpose of a hygienic treatment, said cassette being placeable in a pressure-tight closable chamber of an apparatus so that the instruments are subjected to a treatment process, the improvement comprising the cassette having at least one adapter for holding at least one instrument.

The invention of the present cassette is the advantage that the instrument is placed onto the adapter and can be wetted substantially better by the cleaning fluids. Further, they can be stored on the adapter until the next use.

When, as proposed in the advantageous development of the invention, the adapter will comprise line channels for the delivery of cleaning agents into the internal part and these are connectible to delivery channels and then the instrument can be optimally treated, i.e., cleaned, disinfected and being cleaned with a lubricating oil or the like and then can be sterilized. After the patient treatment, the instruments are placed into the cassette and can remain therein until the complete hygienic treatment. The instruments need not be picked up by the operator in the meantime and need not be placed in the special care means for care, as previously was the case in the prior art in addition, the instruments need not be taken from this care means and placed into a separate sterilizing means.

Other advantages and features of the invention will be readily apparent from the following description of the preferred embodiments, the drawings and claims.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic partially exploded perspective view of an embodiment of the apparatus of the present invention;

FIG. 2 is an exploded perspective view of an instrument cassette in accordance with the present invention;

FIG. 3 is a partial perspective view taken from the rear of the cassette with a closure flap in the closed position;

FIG. 4 is a partial perspective view similar to FIG. 3 with the closure flap in the opened position;

FIG. 5 is a longitudinal cross sectional view through an adapter illustrated in FIG. 2 and a portion of an instrument mating with the adapter;

FIG. 6 is a longitudinal cross sectional view of the cassette of the present invention disposed in the apparatus with portions in elevation for purposes of illustration;

FIG. 7 is a diagram illustrating the hydraulic and pneumatic connections of the present invention;

FIG. 8 is a diagram illustrating the sequence of pulses with respect to time during operation of the device of the present invention; and

FIG. 9 is a modification of the apparatus and cassette illustrated in FIG. 6.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

The principles of the present invention are particularly useful when incorporated in a cassette 12 illustrated in FIGS. 2 and 6, which is used with an apparatus, generally indicated at 1 in FIG. 1.

The apparatus 1 is used for the purpose of a hygienic preparation of various dental instruments. The apparatus contains a housing which forms a chamber 2 on the front side for the acceptance of a cassette 12 (see FIG. 2). The chamber 2 has a plurality of nozzle arms 3 (nine are illustrated) which project into the chamber 2. The instruments are capable of being sprayed on the outside with the assistance of these nozzle arms 3. The chamber 2 has guide beads 4 for the guidance of the cassette arranged on both sides. The chamber 2 can be closed pressure-tight on its front side with a cover or door 5, which operates in a known way.

The housing for the apparatus 1 has a container for demineralized or distilled water which is located adjacent an upper surface of the housing and has a filling opening 6. On the right-hand side near the rear of the apparatus, the apparatus 1 has a diaphragm closure provided in a known way, which closure is punctured by a connection shank 7a when the container 7 is placed on the connection shank so that removal of the lubricant can occur. A door or lid 7b can close the niche that receives the container 7 once the container has been inserted.

The apparatus also has an electrical lead 8, a line 9 for receiving water indicated by the arrow W and an air line 10 which receives compressed air indicated by the arrow L. To assure that a largely germ-free gas or air is available for the method steps set forth in greater detail below, the air line 10 passes through a filter chamber which receives a removable and, thus, replaceable sterile filter 11.

The cassette 12, as illustrated in FIG. 2 in an exploded view, is introducible into the chamber 2 and will receive a plurality of instruments, such as a handpiece 13 and a manual instrument 14. The instrument 13 is shown as either a handpiece or an angle piece whose inside comprises various drive parts and bearings as well as media channels. The instrument 14, by contrast, is a hand instrument that comprises no moving parts and, therefore, has no media channels. The cassette 12 is composed of a base part or a lower part 12a and an upper cassette part 12b which is

removable therefrom. The lower cassette part **12a** is constructed trough-like and contains four different adapters for the acceptance of differently-shaped instruments on a raised backwall **15**. In the exemplary embodiment, the adapter **16** is matched to receive the instrument **13** which is accepted thereon. The four adapters are provided for instruments that comprise moving internal parts and media channels, such as, for example, handpieces, angle pieces, turbine handpieces, handpieces for removing dental tartar or spring handpieces. The instruments that contain no moving internal parts and also contain no media channels, such as, for example, hand instruments **14** in the Figure, are placed on the floor or base of the lower cassette part with a suitable holder for the purpose of preparation.

The backwall **15** of the lower cassette part **12a** also contains bores **17** (nine of which are illustrated), through which the nine nozzle arms or nozzle tubes **3** of the chamber **2** can pass through when the cassette **12** is introduced into the chamber. The arrangement of the nozzle arms and of the bores **17** which correspond thereto is, respectively, a triangular arrangement around the centrally-placed adapters, as illustrated in the Figure.

The upper part **12b** can be placed on the lower cassette part **12a** and can be latched thereto. The upper part **12b** contains lateral guide channels **18** that interact with the above-mentioned guide beads **4** of the chamber and assure the exact centering and guidance of the cassette **12** when it is inserted into the chamber **2**.

At a suitable location, preferably at the floor and in the immediate proximity of the backwall **15**, the cassette is provided with one or more outlet openings **19** for the discharge of the supplied cleaning fluids, as well as any condensed water. This outlet opening or outlet openings are advantageously provided with a part that automatically closes when the cassette is removed from the chamber **2**. These automatic closures can be spring-loaded slides or covers.

The upper cassette part **12b** is advantageously provided with a cover on a back end, and this cover will cover, respectively, both the closing connections leading to the adapter **16** as well as the outlet openings **19** when the cassette is removed from the apparatus. As illustrated in FIGS. 3 and 4, the cover **20** is hinged around a bearing or axle **21**. The movement of the cover occurs automatically when the cassette **12** is inserted into the chamber **2** of the apparatus. To accomplish this, the cover plate **20** comprises a projection **20a** that strikes against the upper edge **22** (FIG. 1) of the chamber **2** upon insertion of the cassette **12** into the chamber. As a result of this, the flap will be tilted upward to the position illustrated in FIG. 4. Thus, the openings **17** located behind the cover plate, as well as the connections, which are not shown in FIG. 4, for the adapters will be uncovered or exposed. Upon removal of the cassette, the cover plate, in turn, automatically pivots or hinges down and, thus, covers the openings so that the hygienically prepared instruments located in the cassette are protected against the penetration of germs, at least for a certain time period.

Alternatively to the automatically opening and closing flap set forth above, a roller shutter element can also be provided. This will effect an automatic covering or, respectively, clearing of the openings or, respectively, connections provided in the backwall **15** with the assistance of a correspondingly provided setting means.

The structure and function of the adapters, as well as the interaction with the instruments that can be plugged thereon,

is illustrated in FIG. 5 with reference to an example of the adapter **16**.

The adapter **16** is provided for connecting a hand and angle piece **13** in FIG. 2. The hand or angle piece **13**, as illustrated in FIG. 5, has an axial bore **13a** which receives bearing **26** that mount a drive shaft **25** for rotation. In addition, the handpiece has media channels **27**, **28** for delivering cooling air and cooling water to a preparation location, and these channels proceed on the interior of the handpiece. The bore **13a** adjacent an open end is provided with ball catches **29**, which will be received in an annular channel, similar to **30**, of a motor housing when the handpiece is inserted thereon to form a connection therewith.

The adapter **16** contains a connecting shank **24** that is structurally matched to the design of the bore **13a** of the instrument. The adapter **16** is fashioned so that the end facing away from the instrument can be secured to the backwall **15** of the lower cassette part **12a** in an easily detachable way. To accomplish this, it contains a catch nose **31** that interacts with an annular channel **37** of a flange or nipple **38** (FIG. 6) that is mounted on the backwall **15** of the lower cassette part **12**.

The adapter **16** has a bore containing a control plunger or spool valve member **32** that is displaceable parallel to the axis of the adapter, and this plunger **32** acts against a spring force so that when the instrument **13** is plugged onto the shank **24**, the control plunger **32** is depressed so that the input channel **33** is connected to a centrally-placed channel **34** and an input channel **35** is connected to an aligned channel **36** which has peripheral openings that are aligned with openings for the media channels **27** and **28** of the instrument. Thus, drive air or lubricating oil can be introduced via the channel **33** to the drive shaft **25** and the bearings **26** and air and water are guided in common in the lines **27** and **28** via the channels **35** and **36**.

When an instrument, such as **13**, is removed from the adapter **16**, the plunger valve will assume the position illustrated in FIG. 5 and interrupt the connection between the inlet channel **33** and channel **34** and also between the channel **35** and channel **36**. This will prevent any supplied media or oil from being emitted from an adapter which is not occupied with an instrument.

As already mentioned, the connection dimensions with respect to the instruments are different for all four adapters mounted in the cassette in order to, thus, be able to hold different instruments. The connecting dimensions with respect to the connector **38** on the backwall **15** of the cassette, however, are the same for all adapters so that they can be easily interchanged with one another or, respectively, can be replaced by adapters having different connecting contours for different instruments.

The allocation of the individual washing and cleaning nozzles or channels is illustrated in FIG. 6 with reference to an example of the instrument **13** and adapter **16**.

In a highly simplified illustration, FIG. 6 shows the arrangement of the cassette **12** in the chamber **2** in the condition wherein the cassette **12** is nearly completely introduced. Corresponding to the plurality of existing adapters, connecting flanges **38** are located on a backwall **15** of the cassette **12** and the adapter is, as already mentioned, capable of being put in place on these connecting flanges **38** in an easily detachable way. The connecting flange **38** has a coupling sleeve **40** that will form a connection with a lead **41** and a sleeve **39** forms a connection with a lead **42**. The lead **42** corresponds to the lead **35** for pressurized water, compressed gas or air and steam indicated by arrow W/L/D,

while the lead 42 corresponds to the channel 33 for lubricant and air indicated by arrow D. Each of the nozzle arms 3 are arranged star-like or, respectively, triangularly around the instrument 13 and are firmly arranged in the housing wall 43 that defines the back side of the chamber 2. These tubes or arms 3 are connected to the line 47 to receive pressurized water, compressed gas and steam, as indicated by arrow W/L/D. The tubes or arms 3 are fashioned as hollow tubes and comprise a plurality of exit openings 44 that are arranged aligned at a specific angle to a surface of the instrument. The nozzle bores are advantageously arranged along the nozzle arm or tube not only in one plane but in a plurality of planes offset relative to one another by a defined angle. The offset can be advantageously arranged zig-zag or wave-like in the longitudinal direction along the reference plane.

As illustrated in FIG. 1, as well as from the following hydraulic and pneumatic connection diagram set forth in greater detail in FIG. 7, nine nozzle arms are advantageously provided for preparing a maximum of four instruments. The arrangement is therefore undertaken so that the nozzle arms are arranged in two rows and offset so that three arms are arranged around an instrument at a respective angle of 120° relative to one another.

Before the method of the invention is set forth in greater detail with reference to the drawings already described and with reference to the hydraulic and pneumatic block circuit diagram of FIG. 7, it should be pointed out that the steam generator 45 connected to the pressurized line 9, as well as the preheating means 46 for water, are accommodated in the apparatus housing in addition to the above-mentioned oil reservoir or container 7. Thus, it should be pointed out that the nozzle arms 3 length from the backwall is limited so that the lid 20 is able to tip from the closed position to the opened position as the projection 20a engages the edge 22 without striking the ends of the tubes 3.

In the hydraulic/pneumatic connection block diagram of FIG. 7, a compressed air supply source 48 and a pressurized water source 49 are connected through the lines 10 and 9, respectively. For purposes of illustration, the filters, oil separators for the compressed air as well as the over-pressure valves that are standard on the input side are not illustrated for the sake of simplicity.

All solenoid valves MV1 through MV16, as well as the water heater 16 and the steam generator 45, are controlled by a microprocessor 50. Reflex or check valves RV are connected in all of the lines.

The injection of a lubricant (maintenance oil mixed with air) from the reservoir 7 occurs pneumatically here via two solenoid valves MV1 and MV12 as well as by a restriction point or throttle point 51. Alternatively, the lubricating oil could also be supplied with a suitable oil pump. The microprocessor 50 controls the valves MV1 through MV9 and MV11 through MV16 so that the agents of water, air and also lubricating oil can be supplied to the adapter 16 and to the nozzle arms 3 separately for each instrument during a method step of pre-cleaning, after-cleaning and, potentially, during the care procedure so that the instruments are cleaned and potentially maintained in chronological succession.

The chronological offset may be seen from the pulse/time diagram of FIG. 8 that shows the chronological course of the valve connections for the various agents of air and water for the four instruments referenced I1-I4. A high cleaning efficiency given a low water consumption is achieved with this chronologically successive cut-in of the agents.

The method utilizing the cassette is as follows:

The cassette 12 is charged with instruments and the instruments that have movable internal parts, such as the angle pieces, turbines, sprays or the like, are plugged onto corresponding adapters 16 of which a maximum of four are allowed in the cassette. The other instruments are placed at a holder device above the floor of the container. The cassettes are then closed by putting the upper cassette part 12b on the lower part 12a and the cassette is introduced into the chamber 2 of the apparatus. During this insertion, the rear cover 20 is lifted and, as a result thereof, the nine nozzle arms 3 extend through the bores 17 of the backwall 15 of the cassette. After the cassette has been inserted into the chamber to such an extent that the connection of lines 41 and 42 with the connectors 39 and 40 (see FIG. 6) has been produced, the cover 5 of the apparatus is closed and the apparatus is turned on.

After a self-test, which lasts approximately half a minute, a cold cleaning of the instruments occurs utilizing cold water which is supplied to the adapter 16 and to the nozzle arms 3 via leads 9 and the lines 41 and 47. The cold water is preferably supplied in a pulsating fashion whereby compressed air at high pressure, which is also pulsating, is mixed with the water into the pulse pauses illustrated in FIG. 8. A high-energy water jet is thus produced and this surprisingly causes a very thorough cleaning of the surfaces and of the inside channels as well. At the same time, the gearing channel is charged with air via a line 42 with the oil delivery valve MV11 remaining closed so that the penetration of dirt and contaminated wash water is therefore prevented. The pulse frequency with which the compressed air is supplied to the water amounts to approximately 3 Hz.

The cold cleaning is ended after about two minutes. The warm cleaning of the exterior surfaces of the instrument and of the inside channels follows thereafter, likewise with a pulsating water jet upon addition of pulsed compressed air. This procedure follows the sequence in the above-mentioned way. After about two minutes of warm cleaning, an intense after-cleaning and a vapor disinfection occurs by blowing the exterior surface of the instruments and of the media and gearing channels in the interior of the instrument off and out with the hot water or water vapor at a temperature in a range of 60° C. through 100° C. To this end, the water is heated by the heater 46 which acts as a flow-through heater. This procedure lasts for about 30-45 seconds.

Care of the moving inside parts follows this intensive after-cleaning by injecting a metered quantity of lubricant from the lubricant reservoir 7. The metering can occur dependent on the adapted instrument and amounts to about 1 gram per instrument in the injection cycle on average. This maintenance step lasts approximately half a minute.

A sterilization of the instrument then subsequently occurs, namely both from the outside as well as from the inside with saturated water steam at a temperature of approximately 134° C. given a pressure of approximately 2-2.5 bar. The sterilization procedure amounts to between 5 and 6 minutes. The sterilization procedure is followed by a drying and cooling of the instrument with cold air. The cooling procedure lasts approximately 3-5 minutes. Given an overall time of approximately 15-20 minutes for preparing the instruments, the cassette 12 with the prepared instruments can be subsequently removed and can be kept ready for use in its closed condition.

The method of execution which automatically sequences in and of itself in the described way can be varied by intervention. For example, on the basis of an appropriate program, pre-selection can be called in at a control and

display panel 52 (FIG. 1) on the front side of the apparatus 1, for example, in that an intermediate drying, for example with air, is implemented following the intensive after-cleaning and disinfection of the external surfaces. An interruption can likewise occur after the maintenance in order to be able to remove articles which are not to be sterilized from the cassette.

For removing existing dry air, particularly from cavities, and particularly from cavities of the instruments, the chamber can be evacuated before the sterilization of the instruments in an advantageous modification. In order to achieve an optimum removal of the dry air, the vacuum should lie in the range of between 40 mbar and 500 mbar absolute. The vacuum can be produced according to a known fractional, multi-step method or according to a pre-vacuum method.

Extremely short times for an optimum, hygienic preparation of the instrument occur with the described method. Due to the pulsating water jet to which high-energy compressed air is supplied in surges, an especially intense cleaning of the parts is obtained. A reliable transport to the treatment location is established in that the instruments can remain in the cassette after the preparation. In addition, the cassette may be used to receive used instruments and store these used or contaminated instruments until they are to be sent for preparation. The instruments contaminated with germs after being used remain in the cassette until they are taken again therefrom and, therefore, a risk of injury to the operating personnel, among other things, is precluded as a result of this procedure. Processing, storing and transport will occur in the cassette. Since the cassette is largely closed, a sterile storing of the instrument is assured over at least an adequately long time, as measured in hours. In that the internal parts and the agent channels are flooded with hot water and steam, a relatively rapid heating time for the overall instrument occurs. A certain lime-dissolving effect is also achieved in the lines due to the fact that the lines are blown out with the water and/or steam and the exteriors are blown off with the water and/or steam. A critical advantage is that no cleaning and drive agent whatsoever need be employed.

A modification or embodiment of the cassette is illustrated in FIG. 9 by a cassette generally indicated as 112. This modification is with regard to the nozzle arms 3. For example, the nozzle arms can be component parts of the cassette, as shown in the exemplary embodiment of FIG. 9, and are mounted in the backwall 15. In addition, even though this would be relatively involved, the nozzle arms can be pivoted around their longitudinal axis and can also be potentially arranged movable in an axial direction. The cover shown in FIGS. 3-5 can alternatively also be a component part of the lower cassette or can be allocated to both cassette halves.

Although various minor modifications may be suggested by those versed in the art, it should be understood that we wish to embody within the scope of the patent granted hereon all such modifications as reasonably and properly come within the scope of our contribution to the art.

We claim:

1. In a cassette having an interior for receiving medical instruments including dental instruments for purposes of hygienic treatment, said cassette being placeable in a pressure-tight closable chamber of a treatment apparatus wherein the interior of the cassette is subjected to a treatment process, the improvements comprising the cassette having at least one adapter for holding at least one instrument, said

adapter comprising line channels for delivering treatment agents into the interior of the instrument and means enabling a direct spraying of all external surfaces of each instrument with treatment agents from a plurality of nozzles or nozzle arms arranged around each instrument.

2. In a cassette according to claim 1, wherein the adapter contains a control valve for closing the line channels of the adapter when the adapter is not occupied with an instrument.

3. In a cassette according to claim 1, wherein a plurality of adapters are provided for different instruments, each adapter having the same connecting dimensions for connecting on a housing wall of the cassette.

4. In a cassette according to claim 3, wherein the adapter is held on a backwall of the cassette by a disconnectible connection.

5. In a cassette according to claim 4, wherein the means for enabling direct spraying has the backwall being provided with openings through which the nozzle arms with the plurality of nozzles are received when the cassette is inserted into a chamber of the apparatus, said openings in the cassette for the passage of the nozzle arms being closed by a cover means having means to open the cover means as the cassette is inserted into the chamber.

6. In a cassette according to claim 5, wherein the cover means is a plate pivotably held at the backwall of the cassette, said plate having a projection engaging an upper housing edge upon introduction of the cassette into the chamber and thereby moving the plate to uncover the openings in the backwall.

7. In a cassette according to claim 5, wherein the cassette is composed of sterilizable plastic.

8. In a cassette according to claim 5, wherein the cassette is composed of two housing halves formed in a transverse division and connectible to one another, the lower housing half having the backwall carrying the adapters and the upper housing half having guide elements for guiding the cassette as it is inserted in the chamber of the apparatus.

9. In a cassette according to claim 1, wherein the cassette is composed of two housing halves formed by transverse division and connectible to one another, the lower housing half having a backwall carrying the adapters and the upper housing having guide elements for guiding the cassette as it is inserted in the chamber of the apparatus.

10. In a cassette according to claim 9, wherein the means for enabling direct spraying includes the nozzle arms with the plurality of nozzles being secured to the cassette and having branches coming into engagement with leads for the treatment agent upon introduction of the cassette into the chamber.

11. In a cassette according to claim 10, wherein each of the adapters has a line channel for delivering a treatment agent into the interior of the instrument.

12. In a cassette according to claim 10, wherein each of the adapters includes a control valve for closing the line channels when an instrument is not applied on the adapter.

13. In a cassette according to claim 10, wherein the nozzle arms and adapters are mounted on a backwall of the cassette.

14. In a cassette according to claim 1, wherein the means for enabling direct spraying includes the nozzle arms being secured to said cassette, each nozzle arm having a plurality of the nozzles, said nozzle arms having connecting branches coming into engagement with leads for treatment agents upon introduction of the cassette into a chamber of the apparatus.
